It has been strongly urged that all men doing executive referee work should be executive officers of the state commission and not of the funds, on the ground that they would be more impartial, that they would be less apt to lean too much to the side of the funds or to the side of the patient, and that both employers and employees would be satisfied with any decision so long as it was given by an impartial person representing the central power of the state. Theoretically this might be so. Practically, officers appointed by the commission would not be responsible to the funds, and could not be held to strict accountability by the funds. It would be a loss of local control and local authority. The local funds represent both employer and workman, and it is necessary that they should control the men on whose decision depends the expenditure of their money. A state referee would not be removable by the funds either for unsatisfactory or for incompetent work, and if he were incompetent, it would not be any advantage simply to transfer him from one fund to another. In our system of government, appointments by governmental commission are more liable to be purely political than appointments by local funds, because the self-interest of the funds would force them to protect themselves against poor appointments. This self-interest in money matters, this self-interest in the expenses of these mutual funds, is the active driving power to keep up the standards of service in sickness insurance. Employers and workmen will be unwilling to see their earnings wasted, and this factor will inevitably prove the force necessary to keep up essential standards.

The personal care of the insured is carried on by panels of physicians. Every legally qualified physician in the state may, on application, be put on the panel or list of physicians willing to do health insurance work in his district Any physician living on the edge of a district or any other physician so desiring may enter his name on one or more panels The proposed law provides that if the medical work in a district is done by salaried physicians or by physicians in establishment funds, the requisite panels shall be formed of these same physicians The insurance provided is not only for the workmen but also for his dependents, and there is contemplated free choice of physicians by the insured, within reasonable geographic distance All persons provided for in the law must be on the list of some physician Free choice of physicians by any patient must be subject to the willingness of the physician to take the patient The local medical committee must have the power to assign to some physician all patients who have not become definitely settled on some physician's list Probably there must be a limit of the number of patients that a panel physician may treat If this is not done the English error of having a small fraction of physicians care for a majority of the patients, producing hurried medical service and inadequate care to the sick, will be repeated Five hundred families, or 1,000 insured, or some such ratio as this, which would give to each physician an average of twenty or thirty patients a day to see, would be a useful maximum This is a matter, however, that could well be left for executive regulation The panel physicians must group themselves together, as such, in order that they may appoint their representatives on the local medical committee and also that the interests of the physicians who are on the panels may be protected by organization Under such organiaztion or through existing medical societies these physicians, should they so desire, may contemplate collective bargaining This collective bargaining should be permitted, but it should not be the only method by which medical service could be arranged Panel physicians must give the sick adequate care for ordinary needs The medical referee as an officer of the funds takes from the panel physicians all responsibility of deciding when a patient is sick enough to receive cash and medical benefits, and when he is well enough to cease to receive these Experience abroad has shown definitely that it is impossible to combine this responsibility with the daily care of the sick in one physician If the physician who has the daily care of the patient must also decide when the patient is to go on the funds or off the funds, as it is called, there is incessant friction There is always the accusation of collusion with the funds to drive sick people to work or of collusion with the patient to put healthy men on the funds or to keep them there Hence the necessity of the medical referee officer of the funds deciding all questions involving beginning, duration and cessation of benefits

The usual body with which the directorate of the fund will deal in medical matters is a definitely organized local medical committee The various regulations necessary for the control of all medical matters in any district, that is, regulations referring to panel physicians, to dispensaries and hospitals, to specialists, and dentists, to the relationship between the panel physicians and the medical referee officers and between doctors, druggists and nurses, and all such relations as are necessary for the intricate running of a health insurance law must be supervised by the local medical committe, composed of representatives of the panel physicians and of representatives of the dispensary and hospital attending staffs, and also — and here is a very important point — a member of the local health department or the local health officer This committee has the power to pass on and report to the directorate of the local fund on all regulations affecting medical matters promulgated by that directorate In the majority of cases these two boards will agree But if they fail to agree, an arbitration committee is to be formed consisting of a representative of the local sick fund, a representative of the local medical committee, and a third person who shall be appointed by a county judge or by a justice of the supreme court This arbitration committee has the final decision in these matters, unless there be an appeal on either side to the advisory medical board and through that to the commission It seems necessary that this local medical committee should have the veto power to be exerted only against the appointment of an unfit medical referee officer by the local sick fund It should not have the power, nor should it be permitted to recommend medical referees to the fund, but it should be able to prevent unfit referees from being appointed This doubtless would be rarely used, but it should be in existence

There should be in many localities, if not in all, a corps of consultants to furnish second opinions This is especially true of small towns which lack dispensary service and may lack sufficient hospital accommodations The consultants may be connected with dispensaries or hospitals, or may not be They should act as referees in purely medical and surgical questions whenever there is an insistent demand or an insistent appeal from the decision of the medical referee officer of the fund

Under the health insurance law the dispensaries would be places for group medicine, that is, for the gathering together of all specialists, and consulting opinions in general medicine and surgery may be secured Any patient can be sent by any physician to the dispensary to obtain special treatment or an opinion on some special condition, or he may be sent to a general practitioner at the dispensary for an opinion on diagnosis or therapeutics This second opinion — that is, this consultation — should be granted to the patient whenever it is demanded by the patient, by the panel physician, by the medical officer of the funds, or by the directorate of the funds Under the panel system every patient is under the care of some panel physician, and therefore panel physicians cannot treat in dispensaries in every day medical and surgical care the patients of other panel physicians Panel physicians can act as consultants in the dispensary, but it would not seem possible to have the ordinary advice in internal medicine in the dispensary as is done today If the panel physician is restricted in the number of patients he can treat, and if patients are not permitted to change their panel physicians except at stated intervals, patients certainly cannot go from physician to physician or from dispensary to dispensary to be treated for ordinary ailments If they are going there with the knowledge of their physician for a second opinion on diagnosis or therapeutics, the dispensary will prove a boon to them and to the community, but if any other condition is allowed, the dispensaries will prove a never ceasing source of trouble, friction and confusion The different specialties can be followed in the dispensary, or the specialists outside the dispensaries can send their patients to men in the dispensaries for the consultant's opinion, if they so desire But here again the division must be made to prevent incessant confusion The dispensaries will be a boon because they will develop into the best examples of group medicine Free dispensaries will cease to exist The medical and surgical care furnished in dispensaries will be paid for the same as to other physicians under the insurance act If, in the community, there remain patients who are not under the insurance law, who desire to go to the dispensary, that is a question outside of the insurance law, and regulations must be promulgated and enforced to regulate such special groups of patients

There must also be ample hospital accommodations for patients who need hospital care Patients sent to hospitals must be attended by members of the staff who are regularly enrolled on the panels A reorganization of the basis on which physicians do their work in municipal hospitals, and even in private hospitals, would have to take place At present, both public and private hospitals accept fees for the treatment of patients under the workmen's compensation laws, but it is forbidden the attending staff to accept any of these fees, and these are kept from them and go to the hospital The exploitation of physicians should cease The men working under the act should receive their just dues for the care of these patients, the hospital charging its just due for their nursing, food and lodging But hospital care and medical care should be distinctly separated, and the whole of hospital nursing expenses should not be charged as is now done to medical fees

We come now to the consideration of the state medical advisory board This forms part of the general state supervision, and should be taken into consideration with the state health insurance commission This advisory board is composed of representatives of the various state medical societies and the state commissioner of health It passes on all regulations relating to medical benefits and on the relation of physicians and surgeons to the insured, and the commission waits for the approval of this board before putting these regulations into effect The commission may put temporary regulations into effect for not more than six months To this medical advisory board are referred all disputes regarding medical benefit that have come from the local committees on appeal through the arbitration committee to the commission This medical advisory board also decides on the standards on which the local medical referee officers shall be appointed, and gives these standards either to the civil service commission to hold the necessary examinations or to some other authorized body whose duty it is to examine these medical referee officers for the local funds In the law as now contemplated the state commissioner of health is a member of this advisory board, but if thought advisable the secretary of the state board of health could be designated The state board of health has the power through him to see that in the standards promulgated by the medical advisory board for the local medical referee officers there shall be included standards of sanitation and preventive medicine which will enable these referee officers to act in an intelligent manner in regard to the questions of preventive medicine and sanitation in their daily duties in supervising the care of the sick under the local funds Moreover, the local medical officer or the representative of the local board of health is on each local medical committee, and the regulations under which the work is done in each district has been passed on by the central health authorities This health insurance law does not detract or take away in any manner from the powers already possessed by the state health department or by any local health department in the state The powers of both the state and the local health departments are widely autocratic and should be so, and they are not hampered or diminished in any way by this act as contemplated This act, as a matter of fact, broadens the field of preventive medicine and sanitation and gives wider and better opportunities than is now possible for the health departments to put into effect their regulations, because the opportunity is here offered to promulgate standards by which men may be appointed and regulations under which officers shall work which shall contain all the necessary provisions for the problems of preventive medicine and for the control of sanitation The idea has been widely disseminated that this health insurance law does not provide for the great problems of preventive medicine and for the sanitation of the community If it does not, it will be due to the failure of the members of the health department of the state and of the local departments to grasp the broad opportunities here offered through the control of their representatives by means of the standards under which they are appointed and the regulations under which they work There is here both local and central control If there arises any dispute between two local committees about sanitary matters, the local power over them possessed by the local health department can quickly force a decision Such power exists today, and there is nothing in the health insurance act to diminish that power If disputes arise between two committees of separate districts, the state health department has control and can exert it The same power is possessed by state and local health departments under this law as is now possessed, and can be exerted, and the same responsibility rests with them to exert it

Under the health insurance law there are also advisory boards to the central state health insurance commission from the local sick funds and also from the trained nurses, appointed by the state society of trained nurses, where one exists The organization of an efficient form of nursing under this law is a necessary feature and one which will be formulated The regulations would probably run parallel to the medical regulations, because harmony between these two sets of regulations will be necessary There will also have to be regulations regarding the prescribing of drugs, both for the economical prescribing of the necessary medicine and the economical provision of surgical supplies and the various appliances, such as eye glasses and trusses These are part of the medical benefits, and are paid for by the local funds They, therefore, come in under the regulation of the board of directors of the local sick fund All regulations regarding them will have to be promulgated in general by the commission, and, if necessary, modified under the advice and guidance of the directorate of the local sick fund These details, however, should be regulated by executive order of the commissioners and not be put into the fundamental organic law of the state There are matters that need quick action, and therefore should not be in that part of the law which requires legislative action to change, but should be left to the discretion of the commission in order that they may be changed at any time

The state health insurance commission appointed by the governor is composed of a chairman, a physician and a third member The medical profession has wisely insisted that it shall be adequately represented on all committees before which their interests would come for decision, and in the scheme here outlined this adequate representation of the profession has been provided and safeguarded in a manner that is just and fair to the profession

The question of remuneration to physicians is one that is not yet decided Some members of the profession insist that it shall be definitely stated in the law They are unwilling to leave it to executive regulation after the law is passed The experience of physicians in some states, especially in Massachusetts and in New York, under workmen's compensation laws, has made them realize that their interests were not safeguarded These laws were passed before physicians realized the responsibilities that would come to them or what their duties would be under the law One of the most noticeable features of the workmen's compensation laws today is the totally inadequate surgical care provided by the law for the really seriously injured person, and the inadequate remuneration which any honorable physician may obtain when caring for any person who is seriously injured

The methods of remuneration should be discussed, There are four possible ways of payment by straight capitation, by visitation, by some variation or combination of these two, or by salaried district physicians By straight capitation is meant that the doctor is paid so much per patient per year This is the scheme which is employed in England, and is the scheme of the ordinary lodge practice and club practice, as seen in this country It is a method of payment which has always produced inadequate service, unsatisfactory to both physician and patient Those who require the greatest amount of care and those who are really sick are the ones who are liable to receive disproportionately less care than they should have These evils are inherent in the method, and it is the condemnation of these evils which has caused such vigorous condemnation and resentment in the profession against the lodge practice and contract practice of today Everywhere an underpaid physician giving inadequate and hurried service is held in contempt by his patients and by his profession The only recommendation for this method is that it is the cheapest and also the easiest method for the funds to calculate how much medical care will cost

The payment by visitation is acknowledged to be the most expensive method, since the physician treats his patient, as in ordinary private practice, and charges each visit pro rata against the funds Expensive though it may be, unless it is proved to be prohibitive, the expense per se is not a valid objection against this method Under this method there is no question that the patients receive the best care It has always proved to be more satisfactory than any other method to both patients and doctors The time honored relationship of confidence and privacy between physician and patient, which from time immemorial has been considered desirable, is best conserved under this method of remuneration In certain towns in Germany, such as Bremen, this is the method employed, and its operation has there proved satisfactory In certain rural districts of Germany it is also the only method under which medical care is given It is urged against it that with an unknown morbidity of disease there is always an unknown expense facing the funds This objection sounds stronger than it really is in fact, because after a few months' trial the varying morbidity of a district can be fairly well gaged, and unless there is some unforseen outbreak of an epidemic, the morbidity as calculated runs along with very little variation of error It is further urged against this method that unnecessary visits may be made If this proves to be true there must be a procedure by which a dishonest physician may be dropped from the panels and, unless reinstated, prevented by law from receiving further remuneration from the insured under the health insurance law The local committees and the physicians on the panels must protect themselves against the action of dishonest physicians This has been done in England and Germany, and can be successfully done here

It is possible that a compromise between the methods of capitation and visitation may be put in force It is a more complicated method than either one of the other two, but, like all compromises, it may appeal to many people The method referred to is that by which the local sick funds give a lump sum to some responsible medical society Physicians give their services by visits and by work done, and calculate each visit and each kind of service as so many points and charge the total number of points against the medical society At the end of each quarter each physician hands in his record of points made, and the total number of points of services given are divided into the total lump sum of money, and each point has a certain value for that quarter, the value of each point varying from quarter to quarter according to the amount of work done The disadvantage of this method is that the more work that is done the more the value of each point diminishes, and there comes a time when, with the amount of money remaining stationary, a period of great morbidity, such as an epidemic, would cause double the amount of work to be performed, and the value of the point would be one-half its value in ordinary times Hence a physician is paid by the law of diminishing returns the greater amount of services he gives This is unquestionably unjust and soon forces the same situation of an overworked physician, underpaid, giving hurried service To obviate this, it is possible to agree that if the morbidity of a district increases above a certain amount, physicians shall be remunerated per point of service done at the rate of the average value of the points as shown in the previous three years This would prevent the injustice of this law of diminishing returns in payment referred to above, and would be a just remuneration on a just basis Of course, under this proposed law there would be 100 per cent collection of all just medical fees, a factor which should be taken into account in considering the remuneration of physicians

The medical organization as outlined here is a well balanced scheme by which the quarrels and friction produced under the health insurance laws of the old world are avoided It gives to the medical profession the standing and the privileges for which the English physicians had to fight — that of adequate representation throughout the entire scheme on the committees before which their interests will come It prevents the incessant wrangling of the German scheme because of the false position in which the physician is there placed, in which he is forced not only to give the daily care to his patients but also to decide when they are put on and off the sick fund In this scheme this decision is relegated to the special medical officer of the funds This medical officer has other functions which safeguard the interests of the patients Because it is his duty to decide whether or not the patient can continue to receive cash benefits, he is in constant touch with the panel physician, and if affairs are not going well medically he can at all times obtain the necessary second opinion and aid to bring about the best care of the patient

All possible disputes between panel physicians and the funds or between patients and the funds are safeguarded by arbitration committees, and the whole scheme of health insurance is delegated to local organizations of funds and physicians by which the real work can be best carried out The proposed plan avoids the English mistake of huge insurance carriers with their thousands of insured scattered helter skelter in masses or individuals throughout the entire country All health insurance to be successful must be locally controlled, and the medical benefits and medical nursing are done by local control under this present scheme

The scheme outlined takes what is best in the German method of giving medical benefits sufficient to guard the health and the best interests of the patients It furnishes not only daily care, but develops the means by which a patient may obtain a second opinion for diagnosis or for therapeutics whenever it is desired The scheme as here promulgated in the dispensaries and hospitals offers not only a better method than is now in vogue, but also the very scheme through which medicine is developing and through which it is bound to develop to the highest degree in the near future — that of group medicine It offers in districts, in which there are no dispensaries or hospitals, consultants from whom the necessary second opinion may be obtained even though the development of group medicine has not proceeded so far as in more densely settled communities This health insurance scheme is also linked firmly together with the present existing powers of the health departments The standards through which the local officers of the funds are appointed are supervised by the health commissioner himself before being promulgated In each local medical committee there is a health officer with the full powers of the health department behind him, and there is in the law a provision that if the medical officers of the funds do not properly report and do not take proper cognizance of sanitation and preventive medicine in their daily work, it is a cause sufficient to bring about their trial and removal from their position Every endeavor has been made to uphold the hands of the present health authorities and continue their present great powers for good As far as organization is possible, as far as it is possible to give power and responsibility, they have been adequately linked together Every endeavor has been made to localize responsibility for the performance of each duty, and with this responsibility the endeavor has been made to give adequate power to perform it This is true of the ordinary every day medical and surgical work of the profession and equally true in the great fields of preventive medicine and sanitation of the health department There remains only the personal equation of the human machine, and the human personal equation until put to the trial is always an unknown quantity

---

Medical Fossils—Occasionally I meet with men who are still living professionally in their undergraduate days, reading the same old books, and writing the same old prescriptions, both blind and deaf to the changed environment Fortunately the more intelligent of the public easily recognize these fossils and appraise them at their true worth They are interesting as relics of the past, but worthless in the present—V C Vaughan M D, *Science,* Dec 8, 1916

A CONSIDERATION OF THE SEROBIOLOGIC REACTIONS AFTER FIVE YEARS OF OBSERVATION *

CHARLES R BALL, MD
ST PAUL

Somebody has said that the serobiologic reactions have created a new science It may also be said they have given us a new symptomatology If we regard them as symptoms and not as *reactions,* they become much easier of understanding and interpretation The lack of understanding concerning them has been due chiefly to two things First, we do not know the source of the so-called antibodies which are necessary for a positive Wassermann, or the origin of the lymphocytosis or increase of globulin content which occurs not only in the spinal fluid but in the blood as well Naturally, then, all our knowledge thus far in regard to these reactions has been obtained by the inductive method, that is, drawing conclusions from individual observations and striking an average or a percentage to be used in the formulation of general rules about them from the sum total of observation

In any knowledge obtained in this way, it is natural to expect that new observations will be reported from time to time which require some modification of previous conceptions In the second place, in the application of general laws to any particular class of cases, there are always the exceptions to be taken into consideration These reactions or symptoms were often found where, from the nature of the case, we did not expect them to occur, or, on the other hand, absent in cases in which, according to our previous knowledge we thought they ought to be If, then, we view these reactions as symptoms, which they certainly are, and study their interpretation in connection with and as we do other symptoms in any case, much of this past confusion in regard to them will disappear We do not expect to find all the symptoms of a disease present in every case Not every case of meningitis presents a Kernig's sign or rigidity of the neck Furthermore, not every case of rigidity of the neck is diagnosed as meningitis Nystagmus is a common symptom of multiple sclerosis, but it would be a serious mistake to regard every case in which the symptoms of nystagmus was present as a case of multiple sclerosis Tremor is an important and frequent symptom of paralysis agitans, yet we would fail to recognize many cases of this affection if we excluded the diagnosis because of the absence of tremor

We must learn to think of the serobiologic symptoms as we do all other symptoms and realize that their value and the interpretation which we give them is not an isolated one, but depends largely on the syndrome accompanying them In this new symptomatology, as in the old, it is not in the typical cases in which the symptoms are present that difficulty in interpretation arises, but in those in which these symptoms are irregular or only partly present

In the beginning of the Wassermann era the impression was quite general that a negative Wassermann made the diagnosis of syphilis extremely doubtful

---

* Read before the Section on Nervous and Mental Diseases at the Sixty Seventh Annual Session of the American Medical Association, Detroit June 1916

* This article and the one by Dr Pilsbury which follows complete the symposium on Syphilis of the Nervous System, which was begun with the articles by Drs Schaller and Riggs and Hammes last week

We are still often confronted with the statement that the Wassermann is negative, as if the final word with reference to syphilis in the case under consideration had been spoken. We know positively at present from records made by hundreds of observers all over the world that in syphilis of all stages a serum Wassermann is found in only about 65 per cent. of the cases. We do not often find it in the primary stage. In the secondary stage it is nearly always present, and in the tertiary in perhaps from 40 to 50 per cent. of the cases. In tabes this symptom is present in from 60 to 70 per cent., in cerebrospinal syphilis in 80 per cent., and in paresis in from 95 to 100 per cent. of all the cases. In my own work, in sixty cases of syphilis without symptoms referable to the nervous system, the Wassermann was positive in thirty-nine, or 68 per cent., in eighty-one cases of cerebrospinal syphilis, in forty-three, or 53.3 per cent., in fifty-seven cases of paresis, in fifty-three, or 92.7 per cent., and in twenty-six cases of tabes, in thirteen, or 50 per cent. It ought to be perfectly plain, from a perusal of such reports, that in a large number of cases of syphilis the serum Wassermann is absent, so that we are able to say positively that the absence of this symptom in the blood serum proves nothing either for or against the assumption of specific disease.

Observation[1] has shown us that a definite relationship between the activity of the syphilitic processes and the Wassermann reaction, as well as the other reactions in the blood and spinal fluid, does not always exist. Late syphilis, bone syphilis, tabes and cerebrospinal syphilis with extensive involvement and active symptoms may give negative reactions, while, on the other hand, cases with strong positive reactions occur in persons who are apparently in good health. A case of paresis, in a complete remission, may give just as strong a positive Wassermann, or just as much of an increase of the lymphocytes in the spinal fluid as an active and rapidly progressive one. There are numerous cases which, after a mild treatment, lose their positive reactions, only to have them return after a short interval. On the other hand, there are cases which, before the beginning of treatment, are negative, but afterward become positive. In one of my cases, a positive serum Wassermann, after the administration of salvarsan intravenously, became negative and remained so, although the clinical condition gradually grew worse and the patient finally died. In another case, a positive reaction remained positive in spite of vigorous treatment, although the symptoms entirely disappeared. Practically all of the authorities at present regard a positive Wassermann as proof of a syphilis either past or present, and the weight of opinion considers that it is present.[2] In other words, a positive Wassermann is thought to mean the presence somewhere in the system of living spirochetes. The exceptions to this rule are so few, about 0.5 per cent., and the other diseases in which it occurs are so easy to differentiate from syphilis by the symptoms and history, that their importance may be considered negligible.

The spinal fluid reactions, especially in obscure conditions, and where the nervous system is involved, are of much more practical value, in both diagnosis and prognosis, than the serum Wassermann. It is quite the vogue now to have a serum Wassermann made on the patient, but to have a thorough examination of the spinal fluid is comparatively rare. In all cases with obscure symptoms referable to the nervous system, the spinal fluid examination is of vastly greater value. In my work I have been much impressed with the large number of cases in which what may be called the cardinal symptoms of nervous syphilis, such as pupil anomalies, Romberg sign, absent knee jerks, and sensory disturbances, were absent, and the symptoms present were few in number and obscure in character. In this category may be mentioned especially neuralgias and paresthesias of the fifth nerve, sciatica, Bell's palsy, persistent insomnia, symptomatic migraine, and choreiform movements not unlike the type occurring in Sydenham's chorea. In many of such cases the serum Wassermann is negative, and unless a spinal fluid Wassermann is made, only serves to mislead one.

Case 1.—A man, aged 40, whose only somatic symptom was a twitching of the left cheek and lower eyelid, subjectively had no complaints. Both the physical and neurologic examinations were negative. A history of a syphilitic infection dating back fifteen years, was obtained. The serum Wassermann was strongly positive. Likewise, the spinal fluid in 0.2 c.c., the lymphocytes were 80/3, the globulin + +, and the colloidal gold test gave the typical paretic curve. Within six months from the date of this examination although specific treatment was begun immediately and continued during this entire period in the form of weekly injections of mercuric salicylate, the patient began to get irritable and quarrelsome, his sleep was disturbed, and he soon became violently insane. This case ran a galloping course, and in a little more than a year the patient died of paresis.

This case is interesting for the reason that six months before the appearance of any somatic or psychic symptoms of paresis, how much longer, no one knows, the serobiologic symptoms of paresis were all present. It is further interesting from a therapeutic standpoint because specific treatment was begun at once, and on the first appearance of mental symptoms, salvarsan intravenously and salvarsanized serum intraspinally were administered and then followed with a course of sodium nucleinate injections, but without any result in staying the progress of the disease.

Case 2 illustrates the incongruity often existing between the clinical and serobiologic symptoms. It also shows how misleading a serum Wassermann and the symptoms which we formerly had to depend on for our diagnosis may be, as well as the value of the spinal fluid examination in every suspicious case.

Case 2.—T., man, aged 45, married, American salesman, examined March 2, 1916, had one brother who died of paresis and another who had an advanced tabes. The patient had been married seventeen years, and had one child living and well; his wife had had no miscarriages. Fifteen years before he had a chancre and mild secondaries; treatment at that time consisted of yellow mercurous iodid pills for about two years. Since then he had had potassium iodid and some mercurial inunctions at intervals, but had not taken any systematic course after the first two years. The only complaint at the present time was a sensitiveness in the upper part of the nose internally and a stuffy feeling in the head as if he had a cold. These symptoms were not constant. The nose and throat specialist whom the patient consulted could find no explanation for them in the nasal passages. The patient visited me, not because of these symptoms, but for the reason that the death of the brother from paresis frightened him, and he wished to find out if any traces of his former syphilis were still present. The serum Wassermann, a luetin test and the neurologic examination all resulted negatively He was then persuaded to have an examination made of his spinal fluid This gave a strongly positive Wassermann with 0 2 c c, the minimal quantity of fluid, a Nonne + +, lymphocytes, 172/3, and the colloidal gold test reacted in the paretic zone Up to the present time the patient's condition continues good

[1] Von Wassermann, A., and Lange, C.: Zur Frage des Entstehens der Reaktions producti bei der Serodiagnostik auf lues, Berl. klin. Wchnschr., March 16, 1914.

[2] Nonne, M.: Syphilis und Nerven System, Ed. 3, p. 813.

It is interesting to note that the origin of the infection in all three brothers was different This argues against the doctrine often expressed of a certain type of syphilis which possesses a special virulence for the nervous system and in favor of the theory of lessened family resistance which is so often observed in other infectious diseases

In a certain type of cases in differential diagnosis the globulin and lymphocyte reactions have been of more value to me than the Wassermann In many cases with organic nervous involvement the Wassermann has been absent in both the serum and spinal fluid, even when 1 c c of the fluid was used, and the diagnosis had to be made from the history, clinical symptoms and the spinal fluid findings without the Wassermann In such cases, with either no history or a negative history of specific infection, the variations in intensity of these two spinal fluid findings, carefully considered, in conjunction with the clinical symptoms, have often proved the deciding factor in making the diagnosis The following cases are illustrative of this

Case 3—B, aged 26, farmer, seen in consultation Dec 26, 1915, could give only an imperfect history on account of his mental condition There was nothing of importance in the family history It was learned from his father that he smoked and drank to excess, but on the advice of a physician had stopped drinking about five months before In June 1915, he began to have paroxysms of pain in the region of the left kidney which were thought to be due to gravel In November, he had a very severe attack of pain lasting several hours From this time on, at night, he began to whistle and sing, and kept up such a disturbance that his room had to be changed so the other members of the family could sleep During the day he seemed rational This condition remained the same until December 4, when he began to have trouble in passing urine He became unable to void it, and some difficulty was experienced in catheterizing him At the time I saw him, December 10, he was delirious all of the time, and had involuntary actions of both bladder and bowels His temperature, although it had been normal for the two days previous to my visit, varied between 101 and 101 6 The pulse ranged between 90 and 112 The patient was rather emaciated and had a slight cough Heart and lungs were negative The urine contained albumin and quite a number of red blood cells The inguinal glands were distinctly enlarged, also, two epitrochlear, about the size of a split pea, were present on each side There was a general tendency to a coarse tremor A suggestion of ankle clonus and a positive Babinski on the left side were the only somatic symptoms observed in the neurologic examination The serum Wassermann was negative A spinal puncture was made December 11 On that day the temperature reached 103 The spinal pressure was slightly increased The spinal fluid was clear, Nonne, +, lymphocytes, 20/3, spinal fluid Wassermann negative with 0 2 and 1 c c of fluid The colloidal gold test gave what might be called a freak reaction, with no change in the first tube, a reddish blue in the second, blue in the third, and no further changes in the remaining tubes On the same day of the puncture mercurial inunctions were begun On the following day, the patient became worse and went into an unconscious condition in which he remained for a week

In this case the enlarged epitrochlear and inguinal glands, as well as the history of development, with delirium coming on at night and disappearing during the day, led one to suspect syphilis On the other hand, the emaciation, slight cough, and the high temperature caused one to feel that tuberculosis was also a probability to be reckoned with From the history and the neurologic examination as well as the spinal fluid findings, it seemed quite certain that the case was a meningitis and that this meningitis was either syphilitic or tuberculous in character After careful consideration of both the reactions and symptoms, tuberculosis was excluded, chiefly because of the mild degree of intensity of the globulin and lymphocyte reaction The position was taken that in any case of tuberculous meningitis in which the symptoms were so extensive and severe, both the globulin and lymphocyte reactions would be much increased The mildness of these reactions was thought to be absolutely out of harmony in a tuberculous meningitis manifesting such acute and extensive symptoms The negative Wassermann in the blood and spinal fluid was given the importance only which should be given to any negative symptoms We know absolutely that we cannot exclude syphilis because the serum Wassermann is negative, and we must come to the same opinion relative to the spinal fluid Wassermann If it is absent we must not, for this reason alone, exclude the possibility of nervous syphilis, but merely apply to its absence whatever other differential diagnostic value this absence may possess It does sometimes have a very particular value, which is well brought out in the next case

Case 4—T, aged 35 merchant married, with two healthy children, stated that his father died from tuberculous meningitis, which was the significant thing in the family history The patient himself, five years before, had a tuberculous affection of the lungs which was at this time apparently quiescent He also gave a history of a specific affection dating back ten years He seemed in good health up to the time of the present illness He had been sick two weeks when I saw him He then complained of a pain in the head and back of the neck His eyes were very sensitive to light He was extremely nervous and restless, with no appetite and bowels constipated His temperature ranged from 99 to 101 The only objective symptom elicited in the physical and neurologic examination was a slight rigidity of the neck muscles The serum Wassermann was negative The spinal pressure increased The spinal fluid Wassermann in 0 2 and 1 c c was also negative The globulin was strongly positive, the lymphocytes 100/3 The goldsol test showed the greatest change in the dilutions from 1 160 to 1 640 In this case the absence of the Wassermann in the spinal fluid taken in connection with the marked increase of the lymphocytes, was very significant According to our past experience all spinal fluids in specific cases with so large a lymphocyte increase had given a positive Wassermann For this reason it was thought that syphilis could be safely excluded Accordingly the diagnosis of tuberculous meningitis was made The subsequent history of the case confirmed this diagnosis

The Wassermann reaction is, of course, the most reliable of all serobiologic symptoms when present in differentiating between nervous syphilis and other organic disease of the nervous system, but it is so often absent, even in the spinal fluid, and there are so many times when the distinction must be made without it, that I have come to depend a great deal on the globulin and lymphocyte reactions in my work The lymphocyte reaction has been especially valuable The diseases in which it occurs with a symptomatology that might be mistaken for syphilis are not numerous, and even then there is usually some factor which in itself is distinguishing, as in the case just reported of tuberculous meningitis, with a negative Wassermann and the large lymphocyte increase

The normal number of lymphocytes in a cubic millimeter has been often stated to be from nothing to five, with a borderland of nine or ten[3] According to my observation, I believe this estimation of the normal number of lymphocytes too high Five lymphocytes to 1 c mm would give fifteen in the 3 c mm in the Fuchs-Rosenthal counting chamber, while the usual count in normal cases for the whole space is certainly much less than this In the following case a pupil anomaly and the lymphocyte count were the most important differentiating symptoms

CASE 5—G, man, aged 40, clerk, unmarried, had been sick about four weeks when he came under my care, he was then incoherent, disoriented as to time and place, and unclean in his habits, with an inclination to expectorate on everybody and everything near him He complained of some headache, which was increased by coughing or sneezing His appetite was excellent, his mental state one of exhilaration and good humor, his memory very poor On account of the mental condition, no past history or history of a present illness was obtainable Physically, his condition was good Pulse and temperature were normal, urine examination was negative Station was bad, and when he attempted to walk he staggered like a drunken man He did not lie still for a second when awake, but kept twitching and jerking, like a person with an aggravated case of chorea The right pupil was larger than the left, but both reacted to light No other pupil anomalies were observed The patient's articulation was good, but he was coarse and loud in his talk Spinal pressure was not increased Both the serum and spinal fluid Wassermanns were negative The globulin reaction was also negative and the lymphocyte count was 18/3, just one more to the cubic centimeter than is given as normal Brain tumor or cerebrospinal syphilis seemed the most probable conditions to be considered However, on account of the number of lymphocytes the latter diagnosis was made This patient made a good recovery with mercurial inunctions and intravenous injections of salvarsan After his recovery a history of specific infection of twelve years' duration was obtained

When even a slight increase in the number of lymphocytes is often so important in deciding the diagnosis, the necessity for obtaining the spinal fluid absolutely free from blood can be readily appreciated The faintest trace of it will give a positive Nonne and a lymphocytosis, and if not detected, lead to erroneous conclusions

The study of these reactions in the spinal fluid was at first almost entirely confined to patients manifesting nervous symptoms Recently, however, a great many observations on their behavior in the spinal fluid in primary and secondary cases of syphilis without any nervous symptoms have been made M Fraenkel[4] was among the first in reporting on the spinal fluid reaction in fifteen cases of untreated secondary syphilis, without evidence of nervous involvement He found the Wassermann positive in five of these cases Dreyfus and Assmann, in a large number of examinations in secondary syphilis, found that the spinal fluid was normal in only 22 per cent of the cases In later examinations on the same patients, 75 per cent of them gave negative reactions

Wile and Stokes,[5] in an article on the spinal fluid in secondary syphilis, conclude that from 60 to 70 per cent of all cases which progress to the secondary stage show some change in the fluid, which indicates a nervous involvement In a later article on the same subject they say "We now feel our figures in our former article were too conservative and in all probability every case of secondary syphilis has an involvement of the nervous system" A consideration of these observations and others similar in character indicates to what extent the study of these reactions have changed our conceptions of syphilis and especially the syphilitic invasion of the nervous system A nervous syphilis has always been regarded as belonging distinctly to the later manifestations of that disease In the light of these recent investigations we may now believe that the nervous system shares in the general invasion of the body during the primary and secondary stages In the great majority of these cases either as a result of treatment or a naturally developed resistance, recovery takes place and the spinal fluid becomes normal Dreyfus has ascertained that in approximately 12 per cent of the syphilitics, without nervous symptoms, examined by him, the spinal fluid has continued pathologic He compares this percentage with the 12 per cent of specific organic nervous affections found by Mattauscheck and Pilcz among 4,000 army officers who had contracted syphilis In commenting on this comparison, Nonne[6] says that the conclusion lies near that these cases in which the fluid remains pathologic are the ones which later on develop the syphilogenic nervous affections The conception at present of the development of a specific nervous disease is then a latency, dating back to the primary and secondary stages, which continues latent until some exciting cause transforms the latent process into an active one Clinical experience is also in harmony with this view In one of my cases, a cerebrospinal syphilis developed several weeks after a severe head injury The patient was apparently well before his accident, but soon afterward he complained of a severe headache and became mentally very dull He also developed a hemiparesis on the right side The spinal fluid gave an increased globulin and lymphocyte reaction These symptoms entirely disappeared with specific treatment

In regard to head injuries, Nonne says, "It has been known for a long time that they can cause an outbreak of brain syphilis, and especially the development of gummatous brain tumor has been observed following such injuries" It is not rational to suppose in these cases that the nervous tissue became infected with spirochetes after the injury from some distant focus The only logical explanation is that these germs were already present in the injured tissues in a latent state, and the injuries so lessened the normal tissue resistance that the latent process was converted into an active one

In prognosis, as has been stated, and as we have seen in the cases reported, neither the number of the reactions present nor their degree of intensity bears any direct relationship to the rest of the symptomatology In Case 3 the syphilitic process was an exceedingly acute and progressive one, yet the only reactions present were the globulin and lymphocyte, and these were mild in character On the other hand, in Case 2 there was entire absence of subjective and somatic symptoms and yet the reactions were all intensely positive Case 1, with a slight twitching of the face as the only somatic or subjective evidence of nervous disease in which all the reactions were strongly positive and which in a short period of time developed into a galloping paresis, would seem to point to a gloomy prognosis when such conditions exist Nonne has reported in this connection thirteen cases in which the reactions were positive, both in the blood and in the spinal fluid Three of these cases were progressive in character, the other ten remained stationary over a period of five years The following case is quoted from Nonne [7]

[6] Nonne M Syphilis und Nerven System Ed 3 p 139

A man, aged 62, formerly a captain, has been a tabetic for fifteen years Mercurial treatment, twelve years ago Since then no specific treatment The pupils do not react to light Knee jerks are absent Hitzig's zone Four years ago Wassermann in blood, + + + Wassermann in spinal fluid, + + with 5 c c of fluid Globulin, +, lymphocytes, + At present practically no change in either the reactions or somatic findings The patient feels well and works every day

This case is not an isolated case, but one of a series of cases which Nonne has observed

The next case is a report on the reactions in an old case of tabes, the first symptoms of which appeared about twenty years ago

Case 6—This case has gradually progressed in a halting way during all of these years and is still advancing The chief discomforts now are a high degree of ataxia, lightning pains which are exceedingly severe in character, and loss of bladder control Feb 15, 1915 the serum Wassermann was slightly positive, spinal fluid examination pressure, normal, globulin, negative, lymphocytes 3/3, colloidal gold test typical in the syphilitic zone, spinal fluid Wassermann, negative in 1 c c March 1, 1916, a little over a year later, the serum Wassermann was negative, spinal pressure normal, globulin, negative, lymphocytes, 6/3, spinal fluid Wassermann negative, colloidal gold test still in the syphilitic zone Except for the colloidal gold test, the spinal fluid reactions, at both examinations, might be considered normal, yet during the period between these examinations, this patient has been practically bedridden because of the high degree of ataxia and has suffered most severely from lightning pains

When such contradictory observations as I have cited are compared, the whole subject of the interpretation of these reactions from the standpoint of prognosis seems to be in confusion The confusion, however, is not so complete as it appears Many cases of cerebrospinal syphilis of the genuine type have been reported in which the spinal fluid became normal, either spontaneously or as a result of treatment In these cases, so far as I know, there have been no relapses reported On the other hand, observations thus far indicate that cases in which there is a pathologic fluid are never safe from relapsing It seems quite plain that we cannot consider any case of syphilis as having recovered, and this applies as much to primary and secondary syphilis as it does to the nervous type until the spinal fluid becomes normal Absence of symptoms and repeated negatives in the blood cannot be regarded as recoveries in those cases in which there is still a pathologic spinal fluid For this reason no patient should be dismissed by the syphilologist and treatment stopped without a complete spinal fluid examination In the so-called cases of parasyphilis, such as tabes and paresis, the outlook for obtaining normal spinal fluids, with present methods of treatment, except in the old *abgelaufene* type (cases in which the disease has spent itself), such as the last case reported, is rather hopeless, and in treating these cases this should be realized

The variations in intensity of the reactions in such cases or the changing of some of the positives into negatives as a result of treatment have, in my opinion, very little value from a prognostic standpoint The following explanation of the reactions in the type of cases represented by Cases 2 and 3, in which such an incongruity exists between the reactions and the symptoms, is suggested In Case 3 the process is an active one and the invasion of spirochetes is limited in extent In other words, it is an active syphilitic process of recent origin and with a good prognosis In the type represented by Case 2, the process is an extensive one The whole central nervous system is invaded, but up to the present time it is latent Sooner or later something will occur to make it active, and then the course will be rapid and severe, as it was in Case 1, in which the conditions were somewhat similar

CONCLUSIONS

The serobiologic reactions should be regarded in the same manner as the symptoms in a clinical picture They furnish only a part of the information, which must be carefully weighed in connection with all of the other facts obtained Often when other symptoms fail, they are found to be present, and give the clue to the proper diagnosis On the other hand, we must not forget that the reverse is sometimes true and they are absent, and then we must depend on the other symptoms for our diagnosis In atypical cases, hard and fast rules cannot be formulated for these reactions any more than for the other symptoms

A spinal fluid examination should be made in all cases in which symptoms are present which are referable to the nervous system, unless the etiology of these symptoms is definitely known

An examination of the spinal fluid is the surest means we have at present of discovering the presence of latent syphilis, and in all cases of syphilis before the patients are discharged from further treatment, this ought to be done, in both early and late cases

In the absence of other symptoms, its findings form the best criteria in deciding when it is safe to stop treatment In the so-called cases of parasyphilis the last statement does not apply because of the impossibility with the present methods of therapy of obtaining a normal spinal fluid

In nervous syphilis, without other symptoms, a normal spinal fluid means a good prognosis and a recovery, a pathologic one, a latency which at any time may become active

Reporting Tuberculosis—The *Monthly Bulletin* of the New York State Department of Health reviews the excuses that physicians give for failing to report cases of tuberculosis, and states that these cannot be regarded as valid by the department All cases, no matter what the organ involved or the stage of the disease, must be promptly reported to the health officer on the special report card, even though the diagnosis was made only at death or necropsy The coroner's certificate of a person dying from tuberculosis may be accepted by the health officer in lieu of a report, but in this instance the health officer must make out a report and send it to the department A laboratory report of sputum positive for tuberculosis will not be regarded as doing away with the necessity of sending a regular report card When the clinical symptoms justify a diagnosis of tuberculosis, the case must be reported by card, even though the laboratory findings are negative for tubercle bacilli If afterward the case proves not to be tuberculosis, the physician may notify the health officer to that effect

MERCURIAL MEDICATION WITH SPINAL DRAINAGE *

L B PILSBURY, M D
LINCOLN, NEB

This is intended to be a brief paper, and few references will be given The literature of syphilis of the nervous system is now so extensive that it properly falls into various categories, though sharp divisions are not always made into clinical, serologic, etc We seem to be no nearer a valid line of distinction between paresis and cerebrospinal syphilis than we were, and most authors are becoming very cautious in their assertions as to what does and what does not constitute paresis There is no reason to suppose that there is any essential difference in the spirochetes in these two conditions, but there is experimental evidence to sustain the view that the spirochete which attacks principally the brain is somewhat different from the one which cripples the heart or assails the liver, as witness a recent communication from the Army Medical School to Dr Archibald Church[1]

On anatomic grounds, Dunlap[2] characterizes general paralysis as "a subacute or chronic inflammatory and degenerative process which goes through and through the great central nervous organs," whereas "the varieties of cerebral syphilis on the other hand, for the most part, play around the surface of the central nervous system, instead of going all through it" In making a serologic distinction, Kaplan[3] considers the colloidal gold test of more value than the Wassermann, and of course the findings in any case of nervous syphilis may have been altered by treatment Kolmer[4] says, "In cerebral syphilis the blood serum, and particularly the cerebrospinal fluid, will react positively less frequently than in general paralysis", but this is doubtful It is sometimes said that the cell count runs higher in cerebrospinal syphilis, but the largest count which I have seen, 360 cells, occurred in the fluid of a patient with undoubted paresis Darling and Newcomb,[5] in four of five cases of cerebrospinal syphilis, failed to find more than six cells, and in a fifth case never found more than 100 They lay stress on the great variation in cell count in these conditions but state that it was no greater in the one condition than in the other They, with Weston,[6] had previously reported three cases of cerebrospinal syphilis in which the cell count never exceeded 3 per cubic millimeter Two of the cases now being reported have never shown to exceed 5 cells per cubic millimeter, and one has varied from 130 to 360, all being cases of paresis

There seems to be no reason for making a distinction in treatment between paresis and cerebrospinal syphilis, and no extravagant hopes can be built on any form of treatment as yet devised in well developed cases of either condition, though prolonged remissions, even in general paralysis, may be expected with vigorous treatment in early cases Gilpin and Earley[7] assume that mercury and arsenic given by any of the ordinary routes fail to reach the cerebrospinal fluid, but this is probably not invariably true, as very small amounts of arsenic have been reported For example, Barbat[8] found 1 part per hundred thousand of metallic arsenic in the fluid immediately following the administration, presumably intravenous, of a full dose of neosalvarsan Gilpin and Earley ask, "Is it not reasonable, then, to think that if we reduce the pressure within the cerebrospinal cavity we may succeed in bringing foreign substances through the capillary walls and thus secure the direct effect of drugs such as arsenic and mercury on the nerve tissue itself?" The plan carried out on three patients reported at that time was repeated lumbar puncture, performed every week or every two or three weeks, together with mercurial inunctions Paresis taboparesis and tabes were represented, and the results were quite encouraging

On theoretical grounds it does not seem that the removal of from 20 to 40 c c of fluid once every week or two should have more than a very transient effect in reducing pressure, and it seems probable that spontaneous variations in pressure may occur from time to time, though doubtless in less degree The fluid is probably rapidly replaced after withdrawal, and it is possible, of course, that the very rapidity might have a tendency to carry over foreign substances which happened to be circulating in the blood at that particular time At any rate, the method seemed worth trying, and ten cases of paresis, taboparesis and cerebrospinal syphilis were so treated, that is, the patients were given mercurial inunctions, 1 dram six days in the week, and were punctured every two weeks with few variations In most cases the inunctions were continuous They were not selected patients, but would represent about the usual hospital run, and some would be a severe test for any form of treatment The amount of fluid withdrawn varied from 20 to 35 c c, the Wassermann was performed with 1 c c of fluid by Dr Clarence Emerson, and the cells were counted in a Thoma-Zeiss chamber with the high power On the whole, the results are not striking, and similar effects might reasonably be expected without spinal drainage One of the patients is decidedly better and several are slightly so, but the one who improved the most had an alcoholic as well as a syphilitic factor None have been treated in this fashion for more than about four months, and none for less than ten weeks, and this is perhaps not time enough for a maximum amount of benefit

REPORT OF CASES

Case 1—White man aged 35, laundryman, married, no children, always intemperate admitted Jan 10, 1916, acquired syphilis at the age of 19 and has had gonorrhea several times with resulting stricture He had a little treatment following chancre, but probably not very much He first showed signs of mental disturbance in July, 1915 after drinking heavily He was excited, nervous, sleepless, suspicious and threatening He spent ten weeks in a general hospital before commitment, and received specific medication, including two intraspinal treatments On admission he was found well oriented, with little disturbance of conduct aside from irritability Right pupil was large and rigid to light, left moderately responsive to light and distance Knee jerks were exaggerated, cremas-

teric, abdominal and gluteal reflexes absent Slight muscular unsteadiness was present The Wassermann reaction was positive in blood serum and later in spinal fluid (Table 1) A diagnosis of cerebral syphilis was made At present the right pupil is large and fixed, while the left reacts only a very little to light The knee jerks are about as they were, and there is about the same amount of muscular unsteadiness The patient is fairly reasonable in his conduct, and cooperates well in treatment

Case 5—White man, aged 48, cigar maker, married, one child aged 20 years, admitted Oct 25, 1915, gave a history of probable chancre occurring a good many years before There was mention in the physician's return of sexual abnormality for ten years, the exact nature not known The symptoms began about July, 1915 with sleeplessness, restlessness, later hallucinations of hearing and delusions of plotting There was no marked alcoholic factor When admitted, the patient showed no disturbance of orientation, but had delusions of influence and acknowledged hearing voices, especially at night He was good-natured, but not euphoric. He had a noticeable speech defect and a little defect in writing The knee jerks were slightly exaggerated but pupils normal, cremasteric and abdominal reflexes present He was paroled from November

24 till January 16 The blood Wassermann was positive, March 18 A diagnosis of paresis was made The spinal fluid Wassermann was variable, and never more than 5 cells were present The physical condition is essentially unchanged, hallucinations and delusions are less prominent, and efficiency is increased The patient takes care of the clothing room in the ward in which he resides

Case 6—White man, aged 44, laborer, divorced, two children, admitted Sept 18, 1915, gave a history of nervousness, speech difficulty and mental confusion for about three months before commitment When admitted he was quiet, a trifle confused, without definite or systematized delusions There was no marked disorientation, but some impairment of memory as evidenced by inconsistent statements Alcoholic intemperance and venereal infection were denied The pupils were slightly unequal and very sluggish to light, knee jerks exaggerated, cremasteric and abdominal reflexes present, movements and station a little unsteady, and speech and writing defective February 23, the blood Wassermann and also the spinal fluid were + + + + A diagnosis of paresis was made The number of cells has been quite variable, but there has been little variation in the intensity of the Wassermann reaction The pupils are now almost rigid to light knee jerks very much exaggerated, tremor and unsteadiness greater than at time of admittance The patient cannot be said to have shown the least improvement under treatment

Case 7—White man aged 38, telephone man, married, who had had no children and whose wife had had no miscarriages, who was not intemperate and who denied venereal infection, admitted Aug 22, 1914, was well oriented, his memory was good, no delusions were present, but his condition was not fully appreciated The pupils were equal, but rigid to light Knee jerks present, also abdominal cremasteric and gluteal reflexes There was considerable tremor, and well marked ataxia There was considerable increase of globulin and albumin, and 115 cells per cubic millimeter in the spinal fluid A diagnosis of paresis was made Mercurial inunctions and potassium iodid were ordered There was a mild paretic seizure Oct 14, 1915 The number of cells has varied considerably, but the number was high at the last count, and the Wassermann still strongly positive The pupils are still rigid, the left knee jerk much exaggerated, and the patient is more tremulous and unsteady now than he formerly was He still does not appreciate his actual condition

* Other than red cells

Case 8—White man aged 47, tailor married, three children, admitted Nov 20 1915, had no history of intemperance or venereal infection About two years before commitment his gait became peculiar and he began to drop things He became very nervous and so forgetful that he could not go on a simple errand and bring back what was wanted About one year before commitment, spinal fluid was negative When admitted, patient was disoriented and showed considerable mental confusion, impairment of memory, judgment, etc The pupils reacted to light and distance the knee jerks were a little exaggerated, and there was slight defect in speech, writing and gait A diagnosis of paresis was made December 6, the spinal fluid showed a slight increase in globulin, but there were only 4 cells per cubic millimeter, the Wassermann reaction was negative in both blood and spinal fluid Since then the spinal fluid Wassermann has been positive three times and negative twice, and the number of cells has never exceeded four There has never been more than a slight increase of albumin and globulin, and the Ross-Jones test was positive only once The knee jerks are now more exaggerated than they were while tremor and muscular unsteadiness are more pronounced

Case 10—White man aged 36 painter single, formerly intemperate, admitted March 14, 1916 one year before com-

mitment had an attack of mental disturbance which lasted about three weeks Shortly before commitment he became excited, sleepless and confused, with hallucinations and illusions When admitted, patient acknowledged having had both gonorrhea and syphilis at the age of 18, but said he was treated and cured Delusions were present and some mental confusion Pupils were sluggish to light, knee jerks exaggerated, tremor present, speech and writing a little defective The Wassermann reaction was + + in the blood and + + + + in the spinal fluid A diagnosis of paresis was made The fluid Wassermann was the same at all examinations since admission Cells have varied from 17 to 85 per cubic millimeter The right pupil is now a little larger than the left and decidedly sluggish to light Otherwise the patient is about the same, except that he is steadier and more efficient in his work

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS SCHALLER, RIGGS AND HAMMES, BALL, AND PILSBURY

Dr J Henry Barbat, San Francisco During the past two years I have been doing experimental work regarding the permeability of the meninges to drugs Patients were given salvarsan, neosalvarsan, and later arsenobenzol intravenously, and immediately after the injection as much spinal fluid as possible was withdrawn by lumbar puncture, usually as much as 60 c c The second half of this fluid was tested for arsenic Twenty-four hours after the first tapping, 20 c.c. of spinal fluid were withdrawn Within one hour after the injection of arsenobenzol, 20 c c of blood were taken and the serum separated from the clot These specimens were all sent to the Hygienic Laboratory at Washington to be tested for arsenic About four fifths of the arsenic is fixed in the body cells within one hour after its intravenous administration leaving only one fifth in the blood, a proportion of about 1 100 000 When neosalvarsan is used a slightly larger proportion of arsenic gets into the spinal fluid than with arsenobenzol In my series of cases the analyses showed an average of 10 per million arsenic in the blood, largely in the serum In the spinal fluid which was drawn twenty-four hours after the administration of the drug, there was found from a trace to 10 per million, the average being one fourth per million The second half of the fluid drawn immediately after the injection of arsenobenzol showed traces of arsenic in 40 per cent of the specimens Carr and Hall demonstrated arsenic in the spinal fluid after the administration intravenously in a very small percentage of cases J J Viton of Buenos Aires showed clearly that the permeability of the meninges depends on whether or not they are irritated or inflamed The injection of homologous serum into the spinal canal will produce leukocytosis, injection of horse serum will produce leukocytosis plus pain and fever Therefore irritation of the meninges, whether by chemicals or other means, will increase the permeability This brings us to the question as to whether the intraspinal injection of any drug has any specific effect in the treatment of any of the cerebrospinal syphilitis lesions I believe that the effect of all these intraspinal injections is to set up a meningitis which, by increasing the blood supply, permits the passage of antibodies and drugs into the spinal fluid enabling them to act more efficaciously on the spirochetes This condition can more easily be brought about by the technic which I spoke about at first

Dr Tom A Williams, Washington, D C One feature of syphilitic meningitis which is so frequently forgotten is the fact that in the tertiary phase, at least, it is not a serositis, the inflammatory condition is not one of the surface of the membrane, but of the deeply seated blood vessels in the membrane. The lymphocytotic reaction is a mere epiphenomenon, so to speak, quite different from the leukocytotic reaction in epidemic meningitis or in pneumococcic meningitis Therefore, in order to affect the disease one must attack the perivascular lymphatic spaces in the meninges What Dr Barbat has just said is, I think, very true Three years ago I considered the real elements of advantage in intraspinal medication I need not repeat what I said in view of what Dr Barbat said Sicard, at the very beginning of salvarsan therapy, made a practice of injecting intraspinally weak salts of mercury while at the same time mercurializing or salvarsanizing the patient, with exceedingly gratifying results, which are not inferior to those which have been so often vaunted as peculiarly efficient by persons using salvarsanized serum I believe that the meningeal reaction produced by the introduction of foreign substance intraspinally is responsible for any advantage there may be, although we do not really know that there is any permanent advantage in intraspinal medication, which must always be combined with systemic medication, whether by salvarsan, preferably, or by mercury as was formerly the case I do not presume to speak of the problem of paresis, for it would take much longer than five minutes to even lay down the ground for it I am talking only of the syphilitic meningitis which eventuates in what is called tabes dorsalis

Dr Albert E Sterne, Indianapolis In the last seven years I have seen no reason to change the estimation of the results of treatment of any form in cases of the kind under discussion I desire to place particular emphasis on the fact that no neurologic examination is complete without a thorough bioserologic survey of each individual case, for undoubtedly the biologic findings guide us correctly, to my mind not only diagnostically, but, still more important, prognostically But so far as the ultimate results of treatment are concerned, I have not been able to convince myself that there is any marked gain We have, possibly, a better temporary result than was formerly secured But the crux of this whole question seems to me to lie in two directions First, we must not fail to recall that we achieved excellent results in the vascular forms of syphilis, not only of the nervous system, but of the body as a whole, but particularly of the nervous system, by the methods employed previous to the use of salvarsan Some of the forms of vascular syphilis affecting the nervous system recovered then as now The results of treatment of parenchymatous syphilis are hardly better now than formerly The happy aspect of the present methods of treatment is this Personally, I believe that every nervous system is affected early after the primary infection If the patient has headaches within the first few weeks following primary infection, his spinal fluid should be examined, when in most instances it will be found to bear the characteristics of an invasion of the central nervous system That is the time, if any time, when we might expect to accomplish something, not only positively curative, but also prophylactically for the prevention of the tertiary degenerative changes in syphilis of the nervous system That is the time to give intraspinal medication I do not care what form you use, whether arsenical or mercurial preparations It has been our habit recently to use the drainage method, but in a slightly different way When we give an intravenous injection we immediately follow it with a spinal puncture, injecting nothing into the spine, but withdrawing spinal fluid, and creating, so to speak, a wave toward the cerebrospinal axis Until we know positively the direction and extent of the flow of the cerebrospinal fluid, we cannot definitely say how much may be gained in this way Owing to the characteristics of the choroid plexus we cannot say, with any degree of assurance, how much or little can be attained, but there is evidence pointing to the fact that we have rapid regeneration of the fluid, and furthermore that at least part of the spinal fluid is derived from the blood With the influx into the cerebrospinal axis we have reason to believe that whatever drugs we place in the blood current will soon reach the cerebrospinal axis after lumbar puncture The time to give intraspinal medication is early, and intravenous medication followed within twenty minutes by spinal puncture would seem to be worthy of trial, in place of direct intraspinal application

Dr Julius Grinker, Chicago I would like to ask Dr Schaller if the presence of the knee jerks in thirteen of the thirty-five cases was really controlled by him, or was it only reported by his interns? It has been my experience that interns will occasionally report the knee jerks as being present in tabetics, when there is only a pseudoreflex present, which is often found in tabetics, and which is merely a voluntary response If he has controlled the findings then the percentage of present reflexes in tabes is rather high in his service My own observation of hundreds of cases of tabetics gives me a smaller percentage of present tendon reflexes As regards the Achilles jerk, it has been my experience that this reflex is very often lost before the knee reflex Referring to the negative Wassermann findings in the spinal fluid of eleven cases of tabes, I wish to ask Dr Schaller whether they were not advanced cases of tabes I have in mind just one case of tabes in which the patient had positive Wassermann findings with symptomatic improvement after intraspinal injections of neosalvarsan by the Swift Ellis method He left the hospital, but returned after a year when repeated Wassermann tests corroborated by an outside laboratory failed to give positive tests The man at his second entry had an advanced case of tabes, he was extremely ataxic and there was no doubt that he was worse, and yet the Wassermann reaction was negative With reference to intraspinal injection of either salvarsan or salvarsanized serum in paretics, and the following remission of symptoms, I think the so-called favorable results are deceptive We must not delude ourselves into believing that we are causing improvement when the improvement is simply a natural phenomenon incident to the disease I have seen tabes patients with extreme ataxia come to the hospital with crutches and after a few injections of salvarsan go out without assistance, but even here we must use extreme caution in estimating the beneficial effects Besides, intraspinal injections are not as harmless as one may imagine In two cases paraplegia followed an injection, in two other cases (not my own) death was the result of intraspinal injection of neosalvarsan The injection of neosalvarsan, even the small dose of 3 mg, has in many instances caused disastrous effects Mercurialized serum injections given intraspinally have in my hands caused violent reactions, high temperatures, and extreme pain In some of the cases there was improvement and in others the reverse It appears then that at the present time we are not quite prepared to say which is the best mode of treating nervous syphilis Certain it is that in both tabes and cerebrospinal syphilis the Swift-Ellis treatment, the most harmless of any deserves still further trial In paresis we may use this method experimentally, though I have still to see the first patient who improved under treatment by any means whatever

Dr Mathew A Reasoner, Washington, D C As to experimental studies of strains of the specific organism of syphilis, a word may not be amiss As the result of isolating twenty strains from various sources, two from the spinal fluid of patients suffering from nervous syphilis and eighteen from chancres and mucous lesions we have satisfied ourselves that there are variations in the strains of syphilis we have studied I am not prepared to say that there are any variations in the morphology of the strains of spirochetes which we have seen In one strain which I obtained from a man who probably committed suicide three months afterward, I did find choroidal involvement in the rabbit This same manifestation was observed with our nervous strains With reference to one statement by Dr Ball, the serobiologic findings must be considered in conjunction with the others In the absence of history or manifestations, one positive Wassermann should not be accepted as proof of syphilis Some one might have mixed the tubes, not to mention other possible sources of error The test should be repeated And likewise in the presence of suspicious manifestations, a negative Wassermann will not be accepted as proof that syphilis does not exist Other methods may be needed to prove it

Dr George H Moody, San Antonio, Tex Excluding here a consideration of all syphilitic affections except paresis and tabes, and coming directly to the question of their treatment, we recall that two or three years ago some believed they had had and were reporting recoveries as the result of arsenical treatment and that a year ago it was practically decided that no patients were getting well It seems to me that all the papers and discussions at this present meeting lead us definitely to our same former position that nobody is recovering from paresis or from locomotor ataxia I ask the essayist if they have observed any deleterious results following the administration of arsenic in large doses? I am afraid that in a few of my cases the degeneration in cases of paresis, especially, has been more rapid after heroic arsenical administration, such as is being advocated and administered I am not certain of this and would like to be convinced a little further if there is any evidence leading to such conclusion Dr Riggs has reported definitely that there seems to have been marked improvement in many cases All of us, perhaps, have had similar observations I know also that many of these patients improved before we gave arsenic at all, under the mercurial treatment, some of them becoming so much improved that for a little while we almost believed them well The point is, Are there any cases in which we are making patients worse as a result of the arsenic? We are now agreed, I think, that formerly we did degenerate many of our patients with paresis and locomotor ataxia by the long administration of heroic doses of the iodids and I believe that none of us are administering them this way to patients at this time Shall we later come to believe that the heroic treatment by arsenic may degenerate some of our patients with paresis and tabes?

Dr Henry F Stoll Hartford, Conn I would like to ask some one who has given more intraspinal treatments than I to explain the following Three patients recently treated were given salvarsan, and within an hour the spinal canal was drained practically dry The next day the patient was given an intraspinal injection In this case the Wassermann reaction in the fluid obtained on the first day was ten times as strong as on the second day, i e, it took ten times as much fluid to get complete inhibition the second day I do not know whether to interpret this as indicating that the newly formed spinal fluid had not had time in which to develop fully its Wassermann bodies, or whether it means that some of the salvarsan had gotten into the spinal fluid

Dr W F Lorenz, Mendota, Wis I doubt the value of removing spinal fluid with the hope of increasing the amount of contained arsenic This practice would seem to me analogous to catheterizing the bladder and by the creation of a vacuum hope to abstract from the blood toxins that may be present It seems to me that the difference in the chemical composition of cerebrospinal fluid and blood plasma is so great that one must conclude that the former is not a simple transudate or filtrate but the product of a secretory tissue Viewing it in that light, a negative pressure on one side would hardly affect the composition of the secretion Several years ago I reported traces of arsenic in the spinal fluid after the intravenous administration of salvarsan In regard to negative Wassermann reactions in syphilitics, I recently succeeded in obtaining a positive reaction with the globulin fraction of such a negative serum The albumin fraction was negative and antagonistic to the binding forces contained in the globulin I could by varying the amounts of globulin and albumin from the same serum create a negative or positive reaction

Dr James B Ayer Boston I thoroughly believe that we can treat successfully a paretic, only we must get the case early I believe that the chief value of all this work during the past five or six years is that it is pushing us back more and more toward the original lesion, so that now the feeling is that we should get patients with nerve syphilis in the secondary stage or the very earliest tertiary stage, and begin the treatment then It sounds radical, but I believe it is rational On the other hand, if we do get a patient late, perhaps after he has had syphilis for five years, if we can pick him up on some slight symptom and find that he is suffering from cerebrospinal syphilis, I believe that often the patient can be cured Perhaps you cannot prove that a seeming neurasthenic is going to be a paretic, but if you find the reactions strongly positive in the blood and spinal fluid, if you get the colloidal gold reaction, you can feel quite certain that that man is an early paretic Such patients are being treated successfully at the present time If in those cases you do not do something, there is every reason to believe that the patient is going to develop general paresis and die from it Even if you save only one in one thousand, you do more than you would by letting them alone or by giving them a little something to relieve the immediate symptoms I thoroughly believe in some form of antisyphilitic serum treatment I am trying now to get serum into the brain under pressure by the lumbar route I believe that is a likely form of treatment

In regard to Dr Stoll's question of the significance of changes in the spinal fluid on two successive injections, I think the work of my colleague Dr Solomon on variations in Wassermann and colloidal gold reactions in different loci of the brain and spinal canal bears on that subject

Dr Robert Henry Haskell, Ionia, Mich I would like to ask if any of the men using the Ogilvie method of treatment have had herpes zoster develop After using the Swift-Ellis treatment, two years ago, I treated two patients by Ogilvie's method Following the initial injection the first patient developed herpes zoster in a rather unusual location He had been in the hospital for some time and there was no other herpes zoster present Two months later another patient developed herpes zoster following treatment, this time a typical shingles Was there any etiologic relation between the injection and herpes? Herpes zoster in general paralysis is not unknown Arsenical zoster is well recognized in dermatology Salvarsan intravenously occasionally has herpes following it but search of the literature has not revealed any such complication following salvarsan intraspinally The French literature contains several instances of cocain administered for spinal anesthesia producing a herpes, and following Camp's observations on spinal cords from patients receiving intraspinal salvarsan treatment, the etiologic relation in these cases appears possible and probable

Dr Malcolm Sumner Woodbury, Clifton Springs, N Y In regard to the question Dr Moody has raised, I do not know that I have positive evidence of deleterious results following subdural treatment I have seen some patients with paresis whom I though were helped by the combined subdural and intravenous methods We have been using mercurialized salvarsanized serum subdurally, supplemented by injections and inunctions of mercury The patient whose case I will report as bearing on the question is one I saw during the last few months and who appeared to be simply a psychoneurotic There was a lurking suspicion that we might have here a case of very early paresis, though physical signs were absent To corroborate the diagnosis the usual serobiologic tests were made As a result we obtained a positive Wassermann on both the blood serum and spinal fluid This patient was put on the ordinary line of treatment intravenously, subdurally and by inunction At two weeks' intervals he received three doses of the mercurialized salvarsanized serum He appeared to be feeling generally very much better Two weeks after the third dose, while coming by train to report for the fourth treatment, he was seized with a sudden manic attack His case has progressed rapidly since that time to a paretic dementia Whether the treatment stimulated the onset of the active symptoms I do not know In regard to the early diagnosis of tabes It seems to me that it is of considerable value for us to pick out the single, individual symptoms which may appear alone and indicate possible tabes I would refer to one case, not particularly unusual, in which loss of vibration sense in the legs was the only indication which we could make out on examination, and in which examination of the spinal fluid corroborated the diagnosis

Dr George A Moleen, Denver Anisocoria, mentioned by Dr Schaller, is not infrequent when tuberculosis, especially of the deeper set of lymphatic glands, is present, and when they exert an irritative influence from pressure on the cervical sympathetic I have found that to be the case Such pressure obviously causes dilatation of the pupil on the ipsolateral side In addition to the symptom mentioned by Dr Grinker, the early recognition of the loss of the Achilles reflex together with loss of the vibratory sense as estimated by the tuning-fork are also important and early symptoms With reference to paresis The first patient received five injections of salvarsanized serum, and recovered so thoroughly that he was able to leave the institution and carry on his ordinary occupation, that of salesman, and did well for a year, but took no other treatments and ignored advice to do so, after the injections But he returned to the hospital with a definite paresis, failed rapidly, and died about a month ago The second patient had three intraspinal injections of salvarsanized serum followed by mercurialized serum The mental confusion disappeared following injections, and he then came down with an apoplectiform seizure, which has left its permanent effects, with no mental symptoms Two other patients, brothers, one with distinct confusion, expansiveness and grandiose ideas, were given intraspinal injections of salvarsanized serum and left the hospital, however, continuing a mercurial course The brother was definitely paretic, with little mental change, but received the same treatment These two cases have been rendered stationary for about a year under the treatment The fifth patient went to California, was given intraspinal treatment and then returned, evidently very much confused, and had to be brought home by attendants He then had about six injections of salvarsanized serum made by the same laboratory in spite of which he progressed rapidly and died about six months after his return A patient with tabes, treated by intraspinal salvarsanized serum and doing well, after involvement of sphincters and marked diminution of visual acuity, was given three salvarsanized serum injections The patient went to New York, where five more injections were given, without changing the cytologic picture or limiting the number of lymphocytes but very little The use of iodin particularly in the form of Lugol's solution, alternated with mercury in some form (blue mass by the alimentary tract being my favorite), has to my mind been a means of at least ameliorating or checking the progress in these cases The method of administering Lugol's solution is 5 or more drops in water or milk before meals and gradually increasing to 50 or 60 drops

As to the Wassermann reaction, if we regard it from its fundamental application it is not specific I favor the clinical findings against the laboratory if there is conflict The reaction is not specific, but is rather a reaction against lipoid bodies which have been shown to be present in other conditions

Dr C Eugene Riggs, St. Paul Dr Ball's paper recalls our own experience with the colloidal gold reaction In over 90 per cent of our cases of paresis we obtained the typical paretic curve, and in over 50 per cent. of our tabetics we observed a distinctive curve, which we believe to be characteristic of tabes Also our cerebrospinal syphilitic cases have almost invariably reacted in the syphilitic zone. There are some bizarre reactions, however, that we all have noted in this colloidal gold test It is not uncommon for us to get the paretic curve in a case apparently of pure tabes I have in mind now one of our cases of tabes which gave the paretic curve This patient has been under observation for the past four years He says he is feeling well The objective signs still obtain but the important point is that there has been no development of mental symptoms, no suggestions of paresis In syphilitic endarteritis one may obtain the paretic curve A German observer has reported its occurrence in puerperal eclampsia We have observed it in disseminated sclerosis We have also obtained this curve in cases of cerebrospinal syphilis, in which the infection had occurred not more than a year previously Just what the significance of this reaction is, it will require further observation to definitely determine Eleven year ago, Dr Dana called attention to the importance of treatment of the early, "the pre-paretic" stage of paresis If we can get these patients early there is a possibility of accomplishing definite results After the disease is well established, and nervous tissues have been disintegrated, they cannot be replaced Our experience, as well as that of Cotton, Ogilvie and many others, has been that very frequently an amelioration of the disease takes place Sometimes we are able to make the patient what we call socially possible He is able to live at home under a restricted environment, much to his own and his family's satisfaction Even if we obtain only an incomplete remission, the patient may be able to straighten out his business affairs, which usually are in a chaotic condition We believe it has been demonstrated that frequency of remission is an accomplished fact as a result either of the intraspinal or of the intensive form of treatment, this means much and of itself makes the treatment of this class of patients well worth while. Answering Dr Moody's question, we have never seen a patient unfavorably influenced by the use of intraspinal medication We have under our care at the present time a paretic who had a remission and then a relapse He is now undergoing his second remission In his case, we have given forty-one intraspinal injections This man is certainly very greatly improved over what he was when he first consulted us

Dr Walter Frank Schaller, San Francisco In reply to Dr Grinker I would say that my comparative figures dealt only with the early tabetic cases As to the tendon reflexes in the lower extremity I have seen all of the cases reported, and practically without exception have examined all of them for the tendon reflexes I have been very careful about the technic, preferring the Babinski reflex hammer, as I think that this instrument is better than any of the others in common use, and is especially desirable for eliciting the Achilles tendon reflex Often instead of striking the patellar tendon with the reflex hammer, I purposely arrest the hammer just before contact in order to eliminate a possible voluntary knee jerk through suggestion I have often been impressed in certain cases by a striking difference between the activity of the Achilles tendon reflex and the patellar tendon reflex, when the former is lost, the latter is found not only to be present but quite lively instead of diminished as one might expect In regard to Dr Moleen's remark about the vibration test, I included this test under "Deep Sensibility" We use the Luer fork and very often find the osseous sensibility reduced to 4-5 on the scale

I was very much interested in what Dr Ball said about the cell count and I believe that this is one of our most accurate diagnostic tests I use the Nageotte cell chamber in which one may count cells in a considerable amount of fluid What Dr Reasoner and Dr Pilsbury had to say about the Wassermann reaction appears to me to be deserving of emphasis I do not accept a Wassermann reaction alone without clinical support as conclusive evidence of syphilis

Dr Charles R Ball, St Paul There is one point in my paper which I would like to emphasize particularly Case 2 was a patient with very active and severe symptoms but negative reactions except for a mild globulin and lymphocytosis The patient in Case 3, on the other hand, had practically no symptoms, either subjective or objective and yet his spinal fluid reactions were such as are usually found in paresis A rational explanation of the difference in the reactions in these two cases may be that in the first case we have an active process with all the congestion and pressure symptoms which accompany active processes but localized and limited in extent In the second case we have a so called latent process but widespread in character with a general invasion of the nervous system In the one case the symptoms are from two sources, first pressure due to hyperemia and swelling, second, the toxin of the spirochete Here the symptoms, due to pressure, predominate In the other case, there is no active process, and consequently, no symptoms which accompany such processes There is simply a mild and chronic toxemia which in time will have its influence on the nervous elements To my mind these two cases illustrate the difference between true cerebrospinal syphilis and parasyphilis (tabes and paresis) In the former, we have the symptoms of a localized and limited inflammation of a mechanical nature predominating The symptoms due to a toxemia are secondary while in the latter the mechanical or pressure symptoms are secondary in character and the toxic predominate The rational explanation to me of the cortical atrophy in paresis and the posterior column degeneration in tabes is that it is toxic in origin, in all probability the toxin of the spirochetes

Dr Lawrence B Pilsbury Lincoln, Neb Two years ago I reported twelve or fourteen patients with paresis treated with intravenous injections of salvarsanized serum Some did badly, two or three at least are still in the hospital apparently no worse than they were two years ago, and have had absolutely no treatment in the last two years of any sort whatever Just how much the salvarsanized serum had to do with the remissions I do not know I also have other cases with prolonged remissions without any treatment I fear that Dr Lorenz took too seriously the suggestion that substances might pass over from the blood into the spinal fluid Yet it does appear from Dr Barbat's results that a small amount of arsenic appears in the spinal fluid in some cases, and some other investigators have obtained the same result I believe it is very important that these patients if they are to be treated intensively should be treated early And if the general practitioner would only send at once to the neurologist his patients with "heat and sun stroke," "fainting spells" etc, and let the latter make a thorough examination of the blood and spinal fluid I think there would be fewer patients with paresis getting to the state hospitals later on in a hopeless stage

THE MASTOID OPERATION OF TEN YEARS AGO AND OF TODAY

BRIEF ESTIMATE OF THE ADVANCE AS MEASURED BY PRACTICAL RESULTS *

PHILIP D KERRISON, MD
NEW YORK

Whatever changes have occurred during the past decade in our method of operating have involved chiefly the treatment of the flaps or soft parts When men differ as to technic they differ usually in advocating either the old wide-open, gauze-packed wounds, with which we are all familiar, or some form of closed or partially closed wound

Undoubtedly a growing respect for the soft parts in mastoid surgery has led to some modifications of surgical method I shall try to show that these changes have not been haphazard, but rather the logical outgrowth of a better appreciation of laws governing wound repair

The Bone Operation—With minor differences to be noted later, the bone operation of ten years ago was practically that in use today Posterior drainage from the vault and thorough removal of diseased bone in whatever direction and to whatever distance this might lead, were then, as now, recognized as the chief surgical aims Complete obliteration of the mastoid cells and removal of the mastoid tip formed part of the prescribed technic Removal of the diploic tissue or intercellular bone structures from the zygomatic region was recognized in theory, but in practice not so generally or so thoroughly carried out as in the operation of today The necessity for removing all overhanging ledges of bone from the margins of the bony wound was insisted on by all competent surgeons In fact, the dislike for sharp and angular bone margins led often to removal of bone posteriorly considerably beyond the limit of the diseased area, this giving rise to exceedingly extensive bone excavations In skilful hands this operation, thus completed, left a large cavity walled by smooth and apparently healthy bone

Treatment of Soft Parts—The wound at completion was flushed with sterile salt solution, dried, and then packed with iodoform or sterile gauze Beginning at the aditus, gauze strips were pressed firmly into every portion of the bone cavity, and were used in such liberal quantity as to project well above the wound level The soft parts were thus held widely separated, the posterior flap being pressed well back to the posterior margin of the extensive bone excavation

Subsequent Dressings—While the outer dressings were commonly changed within twenty-four hours, the wound packing was usually not removed until the fifth day after the operation When first removed, it was not uncommon to find a perfectly clean wound surface of practically bare bone Not infrequently the appearance of the bone cavity at the first change of dressing was identical with that seen at the completion of the operation, with perhaps here and there a bare trace of beginning granulations This in the absence of fluid pus was generally regarded as a favorable condition Should pus or serum have collected at any point between the bone and gauze, it was wiped away The wound was then repacked in precisely the same fashion as the first dressing, except perhaps that slightly less pressure was employed These, or similar dressings, changed on alternate days, constituted from this stage the routine of treatment

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association Detroit, June, 1916

Results—Generally speaking, the results obtained were fairly good and it may be stated that in a majority of cases recovery with complete elimination of the suppurative process took place As offsetting this fact must be mentioned certain recurring mishaps, which seem to have been in some degree attributable to the method in use

1 In a fairly large percentage of ultimately successful cases, healing was unduly delayed, a lapse of ten or twelve weeks or longer between operation and final healing being by no means uncommon

2 In a portion of the cases, certainly much larger than is met with today, secondary operation for removal of diseased bone was necessary

3 In a rather large percentage of cases final healing, usually considerably delayed, occurred with the formation of a permanent and unsightly depression of variable depth occupying the site of the operative bone cavity This unfortunate deformity is exceedingly rare today

4 In a considerable, and formerly puzzling, percentage of cases healing in an apparently healthy wound was delayed, sometimes indefinitely or to the point calling for secondary operation, by persistent failure of the aditus to close This, again, so far as I know, is a rare obstacle to healing in the mastoid operations of today

The foregoing represent perfectly well-defined postoperative conditions which most experienced surgeons have met with That they occur less frequently today than formerly suggests a relation of cause and effect I personally believe that no discussion of an established operation is of the least value which has not some practical aim in view In this sense, the most useful discussion would take the form of an attempted analysis of the occasional causes of failure With this purpose, I shall limit my discussion strictly to the following headlines (1) surgical treatment of the aditus, (2) surgical injuries to bone, (3) influence of pressure on tissue repair, (4) drainage versus tight packing in mastoid surgery, (5) treatment of the soft parts

Treatment of the Aditus—A stage of the simple mastoid operation in regard to which there is as yet no uniformity of practice is the treatment of the aditus Formerly the simple establishment of drainage was by many considered all that is required, and there are surgeons who still hold and maintain this view It seems to me that a rational view on this point might be stated as follows In very recent cases, in which persistent pain or severity of symptoms compel early operation, little treatment of the aditus may be necessary Why curet the aditus if lined by an intact, though swollen, mucosa, easily capable of a return to normal?

Usually, however, the tympanic lesion sufficiently antedates mastoid symptoms to make this region a seat of advanced pathologic change Generally the mucosa is eroded and partly replaced by exuberant granulations If these granulations are only partially removed from the aditus, what remains may shrink and the parts rapidly regain their normal character On the other hand, a small amount of granulation tissue left in this situation may mark the site of a focus of disease in the underlying bone Such a focus of disease, if not surgically removed, may perpetuate the tympanic lesion There is no question that many trying cases of delayed repair and some failures have been due to this cause

Granulations attached to the roof and posterior wall of the aditus may be quickly and radically dealt with Frequently a considerable mass of diploic tissue is attached to the tegmen tympani, thorough removal of which provides a much safer postoperative condition

Granulations occupying the floor of the aditus are frequently attached also to the short process and body of the incus, and greater care is necessary in order to avoid dislocation and even extraction of the incus Particularly in operating on young children is this danger a real one Removal of granulations in this situation often brings the incus into view, and sometimes also the head of the malleus In cases of longstanding tympanic suppuration, which have not reached the stage characterized as chronic suppuration, exposure of one or both ossicles by careful removal of the outer wall of the vault may be necessary in order to bring the vault into a condition favorable to prompt tympanic resolution This, however, is exceptional The contention of some surgeons that the incus should be exposed to view as a routine practice in all mastoid operations does not appeal to me as sound

Surgical Injuries to Bone—In regard to general technic of the bone operation, I would like to refer to one point only Aural surgeons have been particularly slow to see the possible danger of excessive planing or scraping of bone surfaces in mastoid surgery If the inner plates, either by intent or accident, are actually removed over any considerable area, the underlying dura through its abundant blood supply invariably and almost immediately inaugurates the formation of granulations which are the foundation of tissue repair Who has not exposed an area of dura over tegmen or covering the sinus and within a few days seen this membrane absolutely hidden by a layer of healthy granulations? On the other hand, if the boundary plate in any part of the mastoid cavity is scraped or reduced to an extent injurious to its vitality, the process of repair is either retarded or actually fails Theoretically, excessive scraping of the bone may act injuriously in two ways, namely, either by insult to the minute blood vessels within the bone, as a result of which repair is retarded until the vascular supply is reestablished, or by reduction to a point actually destructive to bone vitality Thus we may have only a superficial or surface necrosis, which later is thrown off in the discharge, or the injury may involve the entire thickness of the bone I have seen cases in which, after a puzzling period of delayed repair, the bony covering of the sigmoid sinus has come away almost as a sequestrum, thus paving the way for normal repair

When we have defined roughly but clearly the confines of our mastoid cavity, that is, have revealed in contour its various limiting plates, we shall do well to avoid overtreatment of these surfaces For example, when we have removed in bulk the cells attached to the bony covering of the sigmoid sinus, we see at first in the inequalities of this surface the outlines of the cells, now opened, lying nearest to this plate. With a curet we may easily display our skill in reducing this surface to one of even and polished smoothness. But in doing so we may seriously impair its health and vitality. This, of course, applies equally to other limiting plates of the mastoid cavity. I am convinced that many an operator has blamed himself in cases requiring secondary operation for failure to remove all diseased bone, when in reality he had erred in the opposite direction, that is, in reducing the bone in certain regions to a degree destructive to its vitality.

There are two causes for excessive curetting of bone surfaces in mastoid surgery, namely, (1) the surgeon's fear of overlooking a series of deeper cells still uncovered, and (2) a more or less general impression among aural surgeons that a smooth and even surface is per se a condition favorable to repair. I know of no evidence in support of this view. If the bone is healthy it may, and often does, withstand this treatment, but repair is retarded. If diseased, it is safer to leave uncovered dura than dura covered by diseased bone or bone which has been scraped to a degree leaving its vitality in doubt.

Influence of Pressure on Tissue Repair.—If in mastoid surgery the bone has sometimes received harsh treatment, the blood supply has received even less consideration. It must be remembered that in the old open-wound method of treatment the sole source of blood supply necessary to tissue repair was the bone itself. In addition to the loss of its supporting periosteum, to the occasional injury to bone vessels through excessive use of curets, the bone cavity at completion was subjected to the pressure of tight gauze packing. That this pressure, maintained at least through the first weeks following the operation, should sometimes influence the wound is not surprising.

Occasional Results of Pressure by Gauze Packing.—Tissue repair, proceeding normally in certain areas, is retarded or inhibited at others, at which points the bone, being deprived of its protective and nutrient granulations, suffers a loss of vitality and consequent superficial necrosis. There can be little doubt that a certain percentage of cases coming to secondary operation owe their failure to this cause.

Repair throughout the entire wound surface being retarded, epidermization from the skin margins has extended into the wound cavity, resulting in eventual recovery, but with the formation of an unsightly cavity, or depression, behind the ear.

Repair throughout the bony wound being retarded, the mucosa lining the tympanic vault has spread outward through the aditus to contiguous wound surfaces. As a result of this, closure of this part of the wound has been indefinitely delayed. The nature of this obstacle to closure of a mastoid wound has not been understood, and many patients have suffered prolonged and painful postoperative treatment and some have been subjected to secondary operation who, but for irrational pressure in the region of the aditus and antrum, would have recovered promptly.

A rational deduction from experience which would seem applicable to all fields of surgery might be stated in the form of a law, namely, that *wounds in the process of normal and healthy repair should be subjected to the least possible mechanical disturbance*. Judged by this standard, we bring still another indictment against this method of treatment. Aural surgeons have failed to appreciate that small new processes of tissue repair, delicate new granulation, rudimentary efforts at vascular anastomosis were destroyed or set back at each change of dressing.

The foregoing, in my opinion, represents the defects in theory and practice of the operative methods of ten years ago. Nor is it safe to speak of them as belonging wholly to the past, for, as in every field of endeavor, there are many men of established reputation who, with their immediate followers, are slow to abandon methods learned when they were younger.

The Blood Clot Operation.—In passing I want to say a word about the so-called blood clot operation. Its theory was based on the hypothesis that blood possesses inherent bactericidal properties, and that if the wound is closed at the time of operation, the blood collecting therein not only protects from further infection, but actually provides a reticulum, or scaffolding, through which new granulations and blood vessels are projected, the whole being converted into firm and permanent connective tissue.

A weak point in this theory is the fact that in cases of severe tympanic infection, pus from the vault may escape backward through the aditus, and that even if the blood clot occupying the mastoid cavity is not infected thereby, tympanic drainage is cut off, and tympanic suppuration may be perpetuated. That this danger is real is shown by the number of cases in which ultimate breaking down of the wound occurs. This in some cases takes place shortly after the operation, in others only after a much longer period. These considerations have brought the blood-clot theory as applied to mastoid surgery into disrepute.

While the blood-clot theory as such has never appealed to me, there can be no question as to the important influence which the operation, as originally described under that name, has exerted on the surgical methods and growth of the past decade. It at least proved definitely and beyond dispute the possibility of quicker and on the whole better average results than those obtained by the older methods. Apparently a direct result of the Blake-Reik operation was to stimulate general interest among American surgeons in any rational modification of established surgical methods aiming at quicker average results. Unfortunately the time at my disposal will not permit of even a brief review of the various modified operations which have contributed to our technical knowledge. All that I shall attempt is a brief outline of a simple end operation now in use by many practical surgeons.

Care of the Periosteum.—The initial incision behind the ear should in its central part be placed at least three eighths of an inch behind the auricular attachment. In elevating the flaps an effort to save the periosteum from injury is distinctly worth while. In children and women this is usually not difficult over the upper two thirds of the mastoid. On the other hand, in strong, muscular men, the frequently rough cortex and extensive muscular attachment may make some injury to periosteum even over the upper half of the mastoid inevitable. In any case, attention to this point is of importance, since an intact and unlacerated periosteum is distinctly favorable to postoperative healing.

Treatment of Soft Parts, Drainage.—In healthy wounds, that is, those lined with apparently sound bone and in which no dura has been exposed or even those in which a moderate exposure of healthy dura has been made, the following technic may be followed A wick of gauze, so infolded that no ravel threads may be left when it is withdrawn, is placed in the depth of the wound with one end at the aditus, the other emerging at the lower end of the wound Over this the flaps are approximated and the wound united from its upper extremity to within half an inch of its lower, or tip, end by interrupted silkworm-gut sutures The sutures are carried preferably through the entire thickness of each flap so as to approximate not only the skin, but also the periosteal, edges This is not assured by metal clips A gauze wick fills the auditory canal, and the wound is covered by the usual gauze dressing

Postoperative Treatment —The dressings are changed daily On the day following the operation the wick is withdrawn and very gentle pressure with a pad of sterile cotton is applied over the suture line to express serum or pus through the lower (open) end of the wound The wick removed is then replaced by a much smaller one, which is introduced only from three fourths of an inch to an inch into the wound Thereafter the wicks are changed at each daily dressing until there is evidence that they are no longer required

Dependence on the foregoing treatment is based on the hypothesis that the first wick used establishes a drain or pathway of least resistance along which pus escapes as long as drainage is necessary The small wicks used in subsequent dressings merely maintain the opening at the lower end of the suture line

There are two fairly reliable signs that this treatment is progressing favorably, namely, (1) progressive and fairly rapid return of drum membrane and tympanic structures to their normal appearance, and (2) progressive diminution of discharge

I would abandon this treatment and open the wound in any case in which the tympanic structures did not show progressive improvement On the other hand, I might persist during a considerable period in spite of a fairly profuse, if diminishing, discharge

Interpretation of Pus —It is almost a habit of mind to think of pus as a danger symptom, since it always indicates a focus of infection, present or preexisting In reality, pus per se represents danger only if confined or if its secretion or production is more rapid than its elimination A raw or granulating wound without secretion is, of course, a surgical impossibility Given, therefore, a partially closed wound from which we have reason to believe that we have eliminated the primary focus of infection, we need not be too ready to take alarm at a discharge which may represent only a stage of the process of repair

I have known wounds treated by this method to have every appearance of being practically healed within ten days More wounds are healed within three to five weeks Some for one reason or another do not progress satisfactorily, but after removal of sutures and separation of the flaps, there follows a more rapid process of healing than by the older method

Theoretically this plan of treatment seems to meet the following requirements It provides reasonable and adequate drainage, it utilizes every normal structure, bone and soft parts, in the process of repair, it secures the maximum vascular supply of the parts, it subjects the wound in process of repair to the least possible mechanical disturbance

Contraindications —That there are contraindications to this method goes without saying As such I would consider surgical injuries to the sigmoid sinus, physical signs of disease in an exposed sinus wall, and unusual extension of bone necrosis

Pronounced constitutional symptoms of septic absorption would also call for an open wound, since in such cases the systemic disorder, and not the local lesion, would be the first consideration

Another condition which, though not a contraindication, should be mentioned in this connection is the presence of large tonsils and adenoids, that is, of the obstructive type Two cases from my own experience will illustrate what I mean

In February last I saw, with Dr Howard Gillespie Myers of New York, a child of 3 suffering from bilateral suppurative otitis media Both membranes were bulging, though presenting small perforations The mother had been repeatedly advised to have the tonsils and adenoids removed Double myringotomy did not bring relief, even in reducing temperature Ten days after the myringotomy a double mastoidectomy was performed Following this the temperature returned to normal, but the ears continued to discharge Two months after the operation, the aural discharge still persisting, the tonsils and adenoids were removed Within one week after this operation the aural discharge ceased and both mastoid wounds were healed, leaving, however, a perforation in the left drum membrane which may be permanent

In April last I was called to see R M, a boy of 4 years, whose condition may be summarized as follows Large tonsils and adenoids of obstructive type, acutely inflamed right drum membrane with discharge through small perforation, marked tenderness over right mastoid process

In this case I decided as a first step to remove the tonsils and adenoids, the drum membrane, of course, being incised at the same time Five days later, edema over the mastoid developed, and a mastoid operation after the method here outlined was performed In this case the drum membrane healed promptly and the mastoid wound was completely healed with only a fine linear scar, just three weeks after the mastoid operation

Probably the correct deduction from such cases would be, not that the presence of tonsils and adenoids is a contraindication to any operative method, but rather that tonsils and adenoids of the obstructive type should be removed either as a preliminary step or at the same time as the mastoid operation The latter may seem harsh treatment, but children stand it, and the results justify the additional strain

If the question were asked in what essential feature the operative method here outlined differs from that originally described as the blood clot operation, I should say that a blood clot, allowed entirely to fill the mastoid cavity, may act as an obstacle to pus seeking escape, whereas I should regard as unsurgical any operation which does not take account of and provide adequate drainage

In conclusion, I need not say that I make no pretense to having described a new or original technic The method I have described is that followed by many surgeons today What I have attempted is to show the value of the soft parts and particularly the periosteum in mastoid surgery, and to point out wherein the latter methods are in better accord with sound surgical law

As to comparative results, my own experience may be stated as follows quicker average healing and lessened suffering to the patient, better cosmetic results, that is, practical elimination of unsightly depressions, smaller percentage of failures

58 West Fifty-Sixth Street

ABSTRACT OF DISCUSSION

DR R B CANFIELD, Ann Arbor, Mich All the records and experiments will show the tremendous difficulties we have to overcome in attempting to remove diseased bone in and about the mastoid process Still, it seems to me that the advance that has been made in the distinctly surgical technic of the operation on the mastoid during the past ten years has been along the line of more and more removing as much of the diseased bone and tissue as we can As far as the after-treatment is concerned, the end-result of the successful case is more or less always the same, no matter whether we use one treatment or another, and the after-treatment which interferes the least with Nature is the best Therefore, in deciding on what technic should be used and what advance has been made, we should operate as radically as we can without producing too much deformity, and during the after-treatment leave the case alone, to the benefit of the patient We must remember that all healing takes place in the soft parts, not in the bone, and the condition of the bone of these mastoids which we have to reopen or which we see three to six weeks after operation is a sad commentary on our after-treatment If the mastoid process has been excavated, the bone looks best immediately after the operation, it gets into a less and less satisfactory condition the more we treat it I had an opportunity to compile statistics on the first series of blood clot cases, and although I tried to compile these statistics honestly it seemed to me the paper read much more satisfactorily and gave the idea that blood clot operations are much more satisfactory than an examination of the cases would lead us to believe. I have seen fatal complications arise—cases in which the blood clot was removed better without operation, and it is decidedly a nonsurgical procedure. The best surgical technic is that which removes the greatest percentage of disease, and that after-treatment is best which interferes the least with Nature's healing of the wound

DR. CULLEN F WELTY, San Francisco I do not think that Dr Kerrison has placed sufficient emphasis on the removal of the individual cells The removal of every individual cell that can be found by the Jansen searcher has contributed more to the rapid healing than anything else in the whole field of otology To speak for myself, I rarely operate on a patient the second time That was not so ten years ago In the Politzer clinic twelve years ago, more than 5 per cent required a secondary operation The more thoroughly the cells are removed, the more sure you are of a complete cure. By removing every individual cell to hard bone, I am again assured of the fact that the healing is retarded and there will be more or less depression, granulation tissue does not spring up as readily My cases heal in from three weeks to two months This is not ideal surgery because of the long duration of healing

I do not believe in the blood clot operation because an occasional case will develop a serious brain lesion that would have gone along without any trouble by the open method Some four or five years ago, a New York otologist reported seven deaths following the acute mastoid operation by the blood clot procedure On the other hand, I wish to report 120 cases of my own of acute mastoid operation by the open method without mortality, furthermore, these cases were not selected However, I do feel that some one will devise a safe procedure that will shorten the after-treatment of acute mastoid operations, and it seems to me that it will be along the line of what is now designated as the closed operation

DR JOSEPH C BECK, Chicago Dr Kerrison's review referring to the last ten years' work on the mastoid is very instructive to those who have had anything to do with mastoid surgery You heal a number of patients quickly, and then there will be a few that will not get along, although the same technic was employed It must be something else than the technic employed I am confident that it is a causative factor such as bacteria that originally produces the disease, and the secondary changes of the bones that have to do with the way these conditions heal up There are various types of bone disease and each individual type heals differently Whether this or that method is used the result is usually the same It does, however, matter whether we have tuberculosis, syphilis, or chronic osteitis of purulent character with or without cholesteatoma In discussing this subject of healing we ought to separate acute from chronic cases In the last ten years I have employed a definite technic in a simple mastoid With an uncomplicated case, in which no vital structures are exposed, such as the dura, the sinuses or the labyrinth, the wound is cleaned out completely—I am not particularly enthusiastic about polishing the bone by means of a burr, but after the cavity is clean, the wound is packed loosely with a strip of gauze, a rubber tube is inserted in the opening of the antrum and the drainage gauze and tube allowed to come out through a stab wound The main incision is primarily closed. Just as soon as the discharge from the external auditory canal stops the drain material is removed and the cavity of the mastoid allowed to close just as any other I am now speaking of uncomplicated cases, and I mean by that that the discharge and the hearing correspondingly improved Just as long as there is discharge from the auditory canal I allow drainage from the wound In the radical mastoid the cavity is never packed primarily, and only when that little space between the facial spur and the upper portion of the tegmen begins to narrow, then we sometimes pack lightly We do not now make use of any skin grafting

DR WENDELL C PHILLIPS, New York I am very often asked the question by students and other observers what I consider should be the extent of the mastoid operation, and my invariable reply is that there is no limit to the operation, except the limitations of the disease, and that ought to be the rule that is followed by every operator Unfortunately, the disease so frequently does extend even beyond the confines of the temporal bone that men of limited experience do not completely excavate the diseased bone and thus bring about conditions that require a second mastoid operation I have no doubt that Dr Kerrison meant to imply that the extent of the operation is the limitation of the diseased area I remove the entire area of diseased bone and all granulations excepting at one point, and that is in the tympanic portion of the mastoid antrum I do think it is dangerous to do much curetting around here on account of the danger of disturbing the incus Experience has proved that Nature will attend to the granulations in this area I wish also to say that one of the points where men fail in the simple mastoid operation to get the diseased bone removed is in the region of the zygoma In most of my operations I find it necessary to cut away the cortex over the zygoma as far forward as the middle line of the external auditory canal in order to get to the point of limitation of the disease Regarding the healing process, I quite agree with Dr Canfield that it is not so much the method we follow in the after-treatment as the method we follow in the operation itself You can close the wound largely and drain it with a strip of gauze, and then you will have a sinus that will remain for six or eight weeks before it will heal, or you can leave it wide open and pack it

I must take issue with Dr Welty if I understood him correctly when he inferred that all postoperative temperatures are due to the fact that all the diseased bone has not been removed We know that we have postoperative temperature where the bone has been completely removed, and there are various reasons for it I wish to emphasize one more point in connection with the healing process We all have delayed cases, in which the granulations do not come toward the center, where secretion persists, where there are flabby granulations, especially when an extensive operation has been done Under these circumstances we must look elsewhere for the cause and we all know that there are underlying dyscrasias which may account for it. Here it is wise to call in the family physician and get him to examine the urine, the intestinal organs, and find out if there is not something wrong with the general physical condition of the patient, and it is marvelous what results we get and how rapidly they improve when these conditions are corrected Sometimes as simple a remedy as bicarbonate of soda will have a marvelous effect on the healing process

Dr Philip D Kerrison, New York Dr Beck's reference to bacteria is important—a point I did not take up My paper was intended simply to give certain rational grounds for making a better attempt to utilize the soft parts than has been done in the past My own experience is that this can be done with perfect safety, and with a quicker and a better cosmetic result The soft parts play a more prominent part in the process of repai than aural surgeons generally have considered to be the fact

RENAL FUNCTION IN NEPHRITIS *

ROBERT L I SMITH, SB, MD
Research Fellow, Wesley Memorial Hospital, Chicago
PASADENA, CALIF

In the last few years a vast amount has been written on the subject of renal function and the various methods of its estimation Reviews of the literature have appeared frequently

The present paper is the report of a clinical study of renal function, involving 150 determinations by one of the newer methods — by an index of urea excretion which has been derived from Ambard's laws[1] by F C McLean[2]

Ambard found that

1 When the concentration of the urea in the urine is constant, the rate of excretion varies directly as the square of the concentration of urea in the blood This law is expressed

$$\frac{(\text{Urea in blood})^2}{\text{Rate of excretion}} = \text{Constant}$$

2 When the concentration of urea in the blood is the same, the rate of excretion varies inversely as the square root of the concentration in the urine

$$\frac{\text{Rate of excretion I}}{\text{Rate of excretion II}} = \frac{\sqrt{\text{Concentration II}}}{\sqrt{\text{Concentration I}}}$$

$$\text{or Rate I } \sqrt{\text{Concentration I}} = \text{Rate II } \sqrt{\text{Concentration II}}$$

Introducing this factor into the first law we have

$$\frac{\text{Urea in blood}}{\sqrt{\text{Rate of excretion } \sqrt{\text{Concentration in urine}}}} = \text{Constant}$$

3 Other factors remaining constant, the rate of excretion varies directly with the weight of the individual

$$\frac{\text{Rate}}{\text{Weight}} = \text{Constant}$$

Combining this with the previous formula, we have

$$\frac{\text{Concentration of urea in blood}}{\sqrt{\frac{\text{Rate}}{\text{Weight}} \sqrt{\text{Concentration in urine}}}} = \text{Constant}$$

This formula expresses all of Ambard's laws in the simplest form In order to standardize the formula for use in human subjects, Ambard expresses it as follows

$$\frac{\text{Ur}}{\sqrt{\text{D} \times \frac{70}{\text{Wt}} \sqrt{\frac{\text{C}}{25}}}} = \text{Constant (k)}$$

Ur = Grams of urea per liter of blood
D = Grams of urea excreted per twenty four hours
Wt = Weight of individual in kilograms
C = Grams of urea per liter of urine

This formula is known as Ambard's coefficient, and the value of K usually found in the normal human subject is 0 08 (McLean) The introduction of a standard weight of 70 kg, a standard concentration of 25 gm per liter of urine and the expression of excretion as the rate per twenty-four hours are purely arbitrary, and do not affect the general relationship between the variable factors When these arbitrary factors are kept constant, they, in conjunction with the constant relationship between the four variable factors, tend to keep K constant, and the actual numerical value of K is determined by these arbitrary additions to the formula

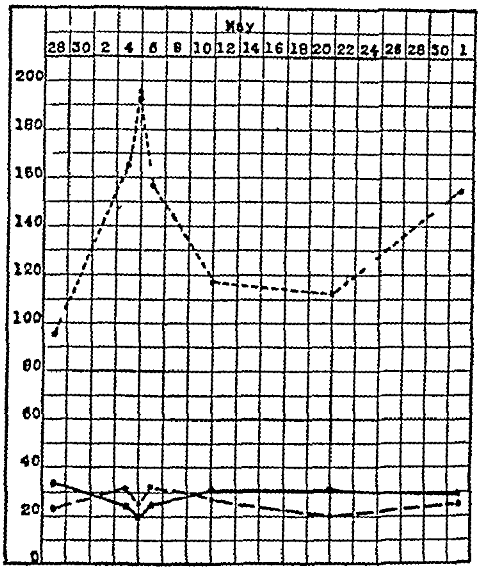

Chart 1 —Normal solid line milligrams of urea per hundred c c of blood, broken line, grams of urea excreted per twenty four hours dotted line index of urea excretion This chart shows the variations as found by McLean in a healthy adult

Index of Urea Excretion —To obviate the necessity of an arbitrary scale for the interpretation of Ambard's coefficient, McLean[2] has adapted a formula from Ambard's laws, based on a scale of 100 so that the rate of urea excretion is given in per cent of the normal, an index of 100 corresponding to a value of 0 08 for Ambard's coefficient

The derivation of the index is as follows

$$\text{Index} = \frac{\text{Rate of excretion}}{\text{Standard normal rate}} \times 100$$

From Ambard's laws

$$1 \quad \text{K} = \frac{\text{Ur}}{\sqrt{\text{Rate}}} \qquad \text{Rate} = \left[\frac{\text{Ur}}{0\ 08}\right]^2$$

$$2 \quad 0\,08 = \frac{\text{Ur}}{\sqrt{\text{Normal rate}}} \qquad \text{Normal rate} = \left[\frac{\text{Ur}}{0\ 08}\right]^2$$

$$3 \quad \frac{\text{Rate}}{\text{Normal rate}} = \frac{\left[\frac{\text{Ur}}{\text{K}}\right]^2}{\left[\frac{\text{Ur}}{0\ 08}\right]^2} = \left[\frac{0\ 08}{\text{K}}\right]^2$$

$$4 \quad \text{Index} = 100 \times \left[\frac{0\ 08}{\text{K}}\right]^2 = \left[\frac{0\ 08}{\text{K}}\right]^2$$

[2] McLean and Selling Urea and Total Non Protein Nitrogen in Normal Human Blood Relation of Their Concentration to Rate of Elimination Jour Biol Chem, 1914, **19**, 31 McLean, F C The Numerical Laws Governing the Rate of Excretion of Urea and Chlorides in Man, Jour Exper Med, 1915, **22**, 212 366 Clinical Determination of Renal Function by an Index of Urea Excretion The Journal A M A Feb 5 1916 p 415

Substituting for K (Ambard's coefficient) and simplifying,

$$\text{Index} = \frac{\text{Gm. urea per 24 hrs.} \sqrt{\text{Gm. urea per liter urine} \times 8.96}}{\text{Wt. in kg.} \times (\text{Gm. urea per liter of blood})^2}$$

When K = 0.08 the standard normal Index = 100.

Methods.—Specimens. The methods recommended by McLean[2] have been used with slight modification. The observations may be made at any time, since the application of the laws is independent of the nitrogen intake. However, it has been considered preferable as a routine to make the observations in the forenoon, no food or water being taken during the period.

The patient is given 300 c.c. of water to drink. One half hour later the bladder is emptied, by catheter if necessary, and the time noted. Then after one or two hours the bladder is again emptied, the time carefully noted, and the amount of urine measured to within 1 c.c. The shorter period is used when the patient is secreting a fairly large amount of urine. At about the middle of the period, 10 c.c. of blood are drawn from a vein into a dry tube containing about 1 gram of potassium oxalate with which it is mixed to prevent clotting.

Analysis. The urease method introduced by Marshall[3] has been used. This depends on the breaking down of urea into ammonia and carbon dioxid by the specific enzyme found in soy bean and the subsequent determination of the ammonia. The permanent preparation of urease described by Van Slyke and Cullen[4] has been used throughout. Three analyses were made in each case: blood urea, urine urea and urine ammonia. The urine ammonia is determined in order to correct the urea figure for preformed ammonia, which is also determined in the urea method.

Calculation of the Index. From the results of the determinations the following calculations are made:

1. Grams of urea excreted per 24 hours = D
2. Grams of urea per liter of urine = C
3. Grams of urea per liter of blood = Ur

These values in the body weight in kilos are substituted in the formula for the index as given above, and the value of the index calculated by aid of a slide rule. With the modified slide rule described by McLean it may easily be calculated in fifteen seconds.

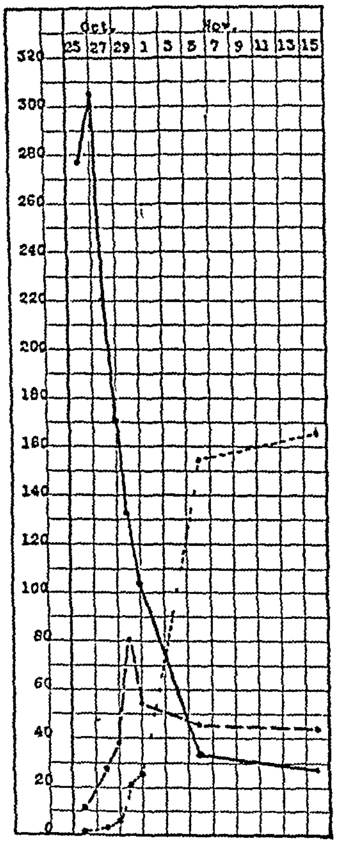

Chart 2.—Uremia: solid line, milligrams of urea per hundred c.c. of blood; broken line, grams of urea excreted per twenty-four hours; dotted line, index of urea excretion.

Nitrogen Intake.—It has been clearly demonstrated[2] that while the nitrogen intake has a direct and marked influence on the concentration of blood urea, it has no effect on the index of urea excretion.

The character of the diet in this series has been included in the tables after each observation. The diet noted as "nephritic" is one which is low in protein and sodium chlorid.

UREA EXCRETION

Urea Excretion in Chronic Nephritis With Hypertension.—Series 1 contains seventy-seven observations made in cases of chronic nephritis with hypertension. It is to be noted that the blood urea ranges from 0.2 to 3.98 gm. per liter. In 62 per cent. of the patients the blood urea is within normal limits (from 0.2 to 0.5 gm.), yet every observation gave an index of urea excretion below normal. The excretion of phenolsulphonephthalein was low or delayed in nearly every instance in which the test was made.

This series[2] again demonstrates the fact that except in extreme conditions the blood urea figure alone does not show the degree of renal impairment; in fact, it is deceptive, as in over 60 per cent. of the cases in Series 1 the blood urea figure is within normal limits. In spite of this large percentage of patients with normal concentration of blood urea, we know that every one in the series had a definite and permanent impairment of renal function. It is only in the individuals with marked renal impairment, who have a low index of urea excretion and a low phenolsulphonephthalein output, that the blood urea figure rises above the upper limit of normal.

It is significant that 100 per cent. of the patients with chronic nephritis and hypertension had an index of urea excretion below normal.

Urea Excretion in Chronic Nephritis With Normal Blood Pressure.—Series 2 contains eighteen observations made on patients with chronic nephritis and normal blood pressure. Of the eight with normal concentration of blood urea, two had a normal index of urea excretion (above 80), four had a slightly lowered (from 50 to 80) and two had an index below 50, which indicates a considerable impairment of renal function. All cases with a blood urea concentration above normal had a low index of urea excretion, that is, one indicating a marked degree of renal impairment. This series is in sharp contrast to the one of chronic nephritis with hypertension in which all cases, regardless of the blood urea figure, have an index of urea excretion below normal. The individuals in this series with normal blood urea tend to have a normal or moderately reduced index of urea excretion, whereas the ones with blood urea concentration above normal all have a low index of urea excretion.

Urea Excretion in a Series of Miscellaneous Cases.—Series 3 contains nineteen observations made on eighteen miscellaneous hospital patients. The cases of plumbism, pernicious anemia and diabetes mellitus had an index of urea excretion below 50. One case of acute plumbism shows the marked reduction of blood urea, from 1.3 to 0.74 gm. per liter, which occurred during the course of twenty-three days of treatment. A corresponding rise (from 1 to 12) is noted in the index of urea excretion.

Urea Excretion in Uremia.—Chart 2 gives in detail a case of uremia in which the patient recovered.

[4] Van Slyke, D. D., and Cullen, G. E.: A Permanent Preparation of Urease and Its Use in the Determination of Urea, Jour. Biol. Chem., 1914, **19**, 211; [illegible]d, The Journal A. M. A., May 16, 1914, p. 1558.

H S, man, aged 32, whose case was diagnosed as chronic gonorrhea, multiple strictures, retention of urine, uremia, gluteal abscesses (colon), and colon bacillus septicemia, came under observation Oct 25, 1915, at which time the pulse was 120 temperature 101 F and respirations 40 per minute He was cyanotic and irrational and had retention of urine The retention was relieved, but the patient continued to grow worse during the day, and 500 c c of blood were withdrawn by venesection The following day (October 26) the patient's condition was apparently the same, although the blood urea concentration was higher October 27 there was a definite improvement in the general condition, and the blood urea had fallen to 2 21 gm per liter From this time on the blood urea continued to fall The urea excretion was at no time low, being at the rate of 11 gm per twenty-four hours, when the patient came under observation It rose to 80 gm, October 29, and then gradually returned to normal The blood urea concentration diminished rapidly after October 26, and the index of urea excretion rose to normal There was a much greater improvement in the general condition of the patient during the time the index of urea excretion increased from 0 5 to 26 than in the time it changed from 26 to 166 The amount of urine voided was at all times large, varying from 1,650 to 4,600 c c in twenty-four hours

UREA INDEX AND PHENOLSULPHONEPHTHALEIN

Although the question as to the agreement of the phenolsulphonephthalein test and the index of urea excretion does not come within the scope of this paper, it is interesting to note that in general the two tests give parallel results There are striking instances, however, in which the tests do not agree A case illustrating this is seen in Chart 3 Clinically this is a case of chronic diffuse nephritis with hypertension The presence of marked impairment of renal function was demonstrated by the presence of a high blood urea concentration and a low index of urea excretion, and the fact that improvement under prolonged hospital treatment was slight and transitory The phenolsulphonephthalein excretion for two hours was 55 per cent While 55 per cent may be considered a little low it does not indicate the degree of renal impairment that actually existed

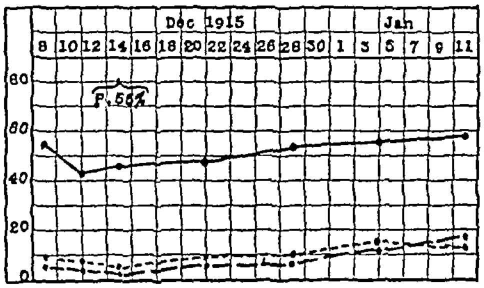

Chart 3—Chronic diffuse nephritis solid line milligrams of urea per hundred c c of blood broken line grams of urea excreted per twenty four hours dotted line index of urea excretion, P percentage of phenolsulphonephthalein excreted in two hours

CONCLUSIONS

1 The index of urea excretion gives much more information as to the degree of renal impairment and the prognosis, than does the blood urea determination *alone*

2 All cases of chronic nephritis with hypertension here studied have impairment of renal function sufficient to alter definitely the relation that normally exists between the urea concentration of the blood and the rate of urea excretion, that is, have a low index of urea excretion

3 The majority of these cases of chronic nephritis with hypertension have a blood urea concentration within normal limits (from 0 2 to 0 5 gm per liter)

4 Chronic nephritis with normal blood pressure may or may not have sufficient renal impairment to alter the relation which normally exists between the blood urea concentration and the urea excretion, that is, it may have a normal or a low index of urea excretion

5 In general the phenolsulphonephthalein test parallels the index of urea excretion, but there are marked exceptions to this rule in which the phenolsulphonephthalein test apparently gives an erroneous idea of the degree of renal impairment

OBSERVATIONS ON IMMUNITY OF MONKEYS TO EXPERIMENTAL POLIOMYELITIS *

E C ROSENOW, M D
ROCHESTER, MINN

E B TOWNE, M D
BOSTON

AND

G W WHEELER, M D
NEW YORK

It is a generally accepted fact that a monkey, after recovery from an attack of experimental poliomyelitis, is immune to subsequent injection with virulent virus It is a question whether an inoculation which does not cause paralysis confers immunity Romer believes that immunity follows unsuccessful intracerebral injection in some cases But there are in the literature many instances in which experimental poliomyelitis has been produced in monkeys which had shown no evidence of infection from a previous inoculation

We wish to record an experiment which appears to indicate that immunity was conferred on three monkeys by inoculations which were not followed by obvious evidence of infection One of the apparently immune animals had previously received an intracerebral injection of a culture of pleomorphic streptococci, the second had received emulsion of central nervous system of animals paralyzed by cultures of streptococci, and the third had received virus in the usual way

Material used for test inoculation—A virus which had been passed successively through four monkeys was employed A 5 per cent emulsion in physiologic sodium chlorid solution of the brain and cord of the fourth animal (Monkey 26) was made immediately after necropsy, November 3 This was ground thoroughly with sterile quartz sand, and shaken for twenty minutes Eight rhesus monkeys were injected in the left frontal lobe with this emulsion Two of these were controls, five had received previous inoculations with virus, filtrate of virus, or culture, and the eighth had received a mixture of the test virus and blood serum from monkeys suspected of being immune Seven of the monkeys which were of approximately the same weight were given 1 c c of the test virus, and the eighth, which was a large, old animal, was given 3 c c

The accompanying table records briefly the results of this experiment For details of the source of material used in the previous injections, reference should be made to the protocols

* From the Mayo Foundation

PROTOCOLS

EXPERIMENT 1—*Control*—Monkey 33 *Macacus rhesus,* 2 6 kg

Nov 3, 1916 Etherized, 1 c c of Virus 751^5 injected into left frontal lobe

November 10 (seventh day) Tremor of arms and legs, rapidly followed by flaccid paralysis of left arm and marked weakness of muscles of the right arm back and legs

November 11 Prostrate Killed with ether Cyst size of pea filled with clear fluid, was found at point of inoculation Microscopic section of brain and cord showed marked typical lesions of experimental poliomyelitis

EXPERIMENT 2—*Control*—Monkey 34, *M rhesus* 7 3 kg

November 3 Three c c of Virus 751^5 injected into the left frontal lobe Immediately after injection there was spastic weakness of the right arm

November 7 Several convulsions Right arm remained almost useless and there was slight weakness of right face and leg Acted sick and ate little

November 10 Better took food well and was active the right arm still weak

November 13 (tenth day) Irritable Coarse tremor of left arm

November 15 General tremor Legs weak could scarcely walk Handling legs appeared to cause pain Knee kicks exaggerated

November 16 Legs flaccid reflexes abolished Left arm tremulous and weak back muscles weak Difficulty in swallowing Killed with ether A cyst about the size of an almond filled with clear deep yellow fluid (old blood) was found at point of injection Microscopic sections of brain and cord showed typical lesions of experimental poliomyelitis

EXPERIMENT 3—*Attempt to destroy activity of virus by mixture with serum of monkeys thought to be immune*—Monkey 37, *M rhesus* 2 8 kg

November 3 Virus serum mixture made as follows Blood was removed from the internal saphenous vein of Monkeys 19 and 21 (which see) previous to their inoculation with the test virus The serums were mixed so that 1 c c contained approximately three parts from Monkey 19 and seven parts from Monkey 21 One c c of the serum mixture was added to 1 c c of the test virus The mixture was filtered through paper kept at a temperature of 35 C for two and one half hours and then in the ice box for fifteen hours

November 4 Etherized Two c c of virus serum mixture (containing 1 c c of Virus 751^5) injected into left frontal lobe

November 19 (fifteenth day) Very excitable Head inclined to the right constant coarse tremor of right neck muscles

November 20 Tremor has extended to muscles of right arm Knee jerks brisk

November 21 Flaccid paralysis of legs back and right arm Left arm weak and tremulous Killed with ether Small cyst containing clear fluid at the point of inoculation Microscopic sections showed characteristic lesions of experimental poliomyelitis

EXPERIMENT 4—*A monkey previously injected intravenously with culture from pus about the teeth of a monkey which did not have pathologic lesions of poliomyelitis was not immune to test virus*—Monkey 21 *M rhesus* 2 5 kg

Previous Inoculation Sept 16 1916—Injected intravenously with 4 c c of a suspension in physiologic sodium chlorid solution of the centrifugal growth from 60 c c of ascites dextrose broth culture of pus around the teeth of Monkey 18, Case 756 This organism appeared in smears from broth as a somewhat elongated diplococcus, occasionally in short chains and on blood agar plate as small dry green producing colonies (Monkey 18 was a domesticated monkey with marked pyorrhea alveolaris, he became spontaneously paralyzed in the animal room When muscle power began to come back he was killed with ether Microscopic sections did not show lesions of poliomyelitis)

September 17 Sick and irritable

September 21 Appeared well Etherized Injected into frontal lobe 1 3 c c of physiologic sodium chlorid solution containing the growth from 20 c c of ascites dextrose broth culture 756 3 (Monkey 18 teeth) This was a second subculture of the culture injected September 16

November 2 Had remained well Blood for serum removed from saphenous vein (compare Monkey 37)

November 3 Etherized One c c. of Virus 751^5 injected into left frontal lobe

November 19 (sixteenth day) Irritable and tremulous, with weakness of legs

November 20 Flaccid paralysis of both legs Wrist drop on right

November 26 Right arm and back muscles gone Left arm weak and ataxic but could be used to take food Good appetite

December 5 Improving able to sit up Arms were stronger but markedly ataxic Legs could be moved a little

December 15 Got about quite well Legs paretic and began to show contractures

EXPERIMENT 5—*A monkey injected intracerebrally with filtrate of brain and cord of a monkey which did not have pathologic lesions of poliomyelitis was not immune to test virus*—Monkey 24 *M rhesus* 2 3 kg

Previous Inoculation October 5—Etherized One and five tenths c c of Berkefeld N filtrate of Virus 737^2 (glycerinated brain and cord of Monkey 16) injected into left frontal lobe (Monkey 16 was inoculated with a filtrate of mixed human and monkey virus and developed muscular weakness but microscopic sections did not give the picture of experimental poliomyelitis)

November 3 Had remained well Etherized One c c of Virus 751^5 injected into left frontal lobe

November 10 (seventh day) Irritable, with rapid tremor of neck and shoulder muscles Internal squint apparently due to weakness of right sixth nerve General muscular weakness

November 13 Markedly ataxic Left arm awkward

November 17 Less tremor Both arms weak especially the right which showed complete wrist drop Right leg tired quickly No knee jerk on right Strabismus less marked Photophobia

November 26 Improving Shaky and weak took food well

December 15 Very active showed only some residual weakness of right arm slight internal strabismus and photophobia

EXPERIMENT 6—*Example of apparent immunity conferred by inoculation with filtrate and virus seven weeks previously without evidence of infection*—Monkey 17 *M rhesus* 2 5 kg

Previous Inoculation September 13—Etherized Injected into frontal lobe 1 5 c c of Virus 737 (compare Monkey 24) which had been passed through a dense porcelain filter

September 19 Had remained well Etherized Seventy five hundredths c c of fresh human Virus 729 injected into frontal lobe

November 3 Had remained well Etherized One c c of Virus 751^5 injected into left frontal lobe

RESULTS OF TEST INJECTIONS OF A VIRULENT VIRUS

H. S., man, aged 32, whose case was diagnosed as chronic gonorrhea, multiple strictures, retention of urine, uremia, gluteal abscesses (colon), and colon bacillus septicemia, came under observation Oct. 25, 1915, at which time the pulse was 120, temperature 101 F. and respirations 40 per minute. He was cyanotic and irrational and had retention of urine. The retention was relieved, but the patient continued to grow worse during the day, and 500 c.c. of blood were withdrawn by venesection. The following day (October 26) the patient's condition was apparently the same, although the blood urea concentration was higher. October 27 there was a definite improvement in the general condition, and the blood urea had fallen to 2.21 gm. per liter. From this time on the blood urea continued to fall. The urea excretion was at no time low, being at the rate of 11 gm. per twenty-four hours, when the patient came under observation. It rose to 80 gm., October 29, and then gradually returned to normal. The blood urea concentration diminished rapidly after October 26, and the index of urea excretion rose to normal. There was a much greater improvement in the general condition of the patient during the time the index of urea excretion increased from 0.5 to 26 than in the time it changed from 26 to 166. The amount of urine voided was at all times large, varying from 1,650 to 4,600 c.c. in twenty-four hours.

UREA INDEX AND PHENOLSULPHONEPHTHALEIN

Although the question as to the agreement of the phenolsulphonephthalein test and the index of urea excretion does not come within the scope of this paper, it is interesting to note that in general the two tests give parallel results. There are striking instances, however, in which the tests do not agree. A case illustrating this is seen in Chart 3. Clinically this is a case of chronic diffuse nephritis with hypertension. The presence of marked impairment of renal function was demonstrated by the presence of a high blood urea concentration and a low index of urea excretion, and the fact that improvement under prolonged hospital treatment was slight and transitory. The phenolsulphonephthalein excretion for two hours was 55 per cent. While 55 per cent. may be considered a little low, it does not indicate the degree of renal impairment that actually existed.

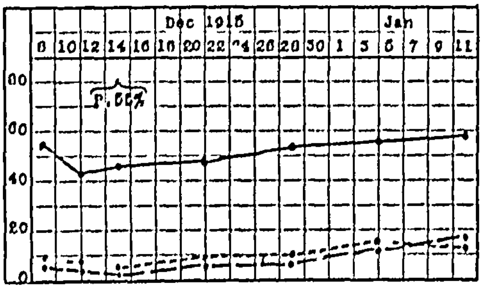

Chart 3.—Chronic diffuse nephritis: solid line, milligrams of urea per hundred c.c. of blood; broken line, grams of urea excreted per twenty-four hours; dotted line, index of urea excretion. P, percentage of phenolsulphonephthalein excreted in two hours.

CONCLUSIONS

1. The index of urea excretion gives much more information as to the degree of renal impairment and the prognosis, than does the blood urea determination alone.

2. All cases of chronic nephritis with hypertension here studied have impairment of renal function sufficient to alter definitely the relation that normally exists between the urea concentration of the blood and the rate of urea excretion, that is, have a low index of urea excretion.

3. The majority of these cases of chronic nephritis with hypertension have a blood urea concentration within normal limits (from 0.2 to 0.5 gm. per liter).

4. Chronic nephritis with normal blood pressure may or may not have sufficient renal impairment to alter the relation which normally exists between the blood urea concentration and the urea excretion, that is, it may have a normal or a low index of urea excretion.

5. In general the phenolsulphonephthalein test parallels the index of urea excretion, but there are marked exceptions to this rule in which the phenolsulphonephthalein test apparently gives an erroneous idea of the degree of renal impairment.

OBSERVATIONS ON IMMUNITY OF MONKEYS TO EXPERIMENTAL POLIOMYELITIS*

E. C. ROSENOW, M.D.
ROCHESTER, MINN.
E. B. TOWNE, M.D.
BOSTON
AND
G. W. WHEELER, M.D.
NEW YORK

It is a generally accepted fact that a monkey, after recovery from an attack of experimental poliomyelitis, is immune to subsequent injection with virulent virus. It is a question whether an inoculation which does not cause paralysis confers immunity. Römer believes that immunity follows unsuccessful intracerebral injection in some cases. But there are in the literature many instances in which experimental poliomyelitis has been produced in monkeys which had shown no evidence of infection from a previous inoculation.

We wish to record an experiment which appears to indicate that immunity was conferred on three monkeys by inoculations which were not followed by obvious evidence of infection. One of the apparently immune animals had previously received an intracerebral injection of a culture of pleomorphic streptococci, the second had received emulsion of central nervous system of animals paralyzed by cultures of streptococci, and the third had received virus in the usual way.

Material used for test inoculation.—A virus which had been passed successively through four monkeys was employed. A 5 per cent. emulsion in physiologic sodium chlorid solution of the brain and cord of the fourth animal (Monkey 26) was made immediately after necropsy, November 3. This was ground thoroughly with sterile quartz sand, and shaken for twenty minutes. Eight rhesus monkeys were injected in the left frontal lobe with this emulsion. Two of these were controls, five had received previous inoculations with virus, filtrate of virus, or culture, and the eighth had received a mixture of the test virus and blood serum from monkeys suspected of being immune. Seven of the monkeys which were of approximately the same weight were given 1 c.c. of the test virus, and the eighth, which was a large, old animal, was given 3 c.c.

The accompanying table records briefly the results of this experiment. For details of the source of material used in the previous injections, reference should be made to the protocols.

---

* From the Mayo Foundation.

PROTOCOLS

EXPERIMENT 1.—*Control*.—Monkey 23. *Macacus rhesus*, 2.6 kg.

Nov. [illegible], 1916. Etherized. 1 c.c. of Virus 721 injected into left frontal lobe.

November 10 (seventh day). Tremor of arms and legs, rapidly followed by flaccid paralysis of left arm and marked weakness of muscles of the right arm, back and legs.

November 11. Prostrate. Killed with ether. Cyst size of pea filled with clear fluid, was found at point of inoculation. Microscopic section of brain and cord showed marked typical lesions of experimental poliomyelitis.

EXPERIMENT 2.—*Control*.—Monkey 24. *M. rhesus*, [illegible] kg.

November [illegible]. Three c.c. of Virus 721 injected into the left frontal lobe. Immediately after injection there was spastic weakness of the right arm.

November 7. Several convulsions. Right arm remained almost useless and there was slight weakness of right face and leg. Acted sick and irritable.

November 11. Better; ate food well and was active; the right arm still weak.

November 1[illegible] ([illegible] day). Irritable. Coarse tremor of left arm.

November 1[illegible]. General tremor. Legs weak; could scarcely walk. Handling legs appeared to cause pain. Knee jerks exaggerated.

November 16. Legs flaccid; reflexes abolished. Left arm tremulous and weak; back muscles weak. Difficulty in swallowing. Killed with ether. A cyst about the size of an almond filled with clear, dark yellow fluid (old blood) was found at point of injection. Microscopic sections of brain and cord showed typical lesions of experimental poliomyelitis.

EXPERIMENT 3.—*Attempt to neutralize virus by mixture with serum of monkeys thought to be immune*.—Monkey 27. *M. rhesus*, 2.8 kg.

November [illegible]. Virus-serum mixture made as follows: Blood was removed from the internal saphenous vein of Monkeys 19 and 21 (which see) previous to their inoculation with the test virus. The serums were mixed so that 1 c.c. contained approximately three parts from Monkey 19 and seven parts from Monkey 21. One c.c. of the serum mixture was added to 1 c.c. of the test virus. The mixture was [illegible] through paper, kept at a temperature of [illegible] C. for two and one-half hours and then in the ice box for fifteen hours.

November [illegible]. Etherized. Two c.c. of virus-serum mixture (containing 1 c.c. of Virus 721) injected into left frontal lobe.

November 19 (fifteenth day). Very excitable. Head inclined to the right; constant coarse tremor of right neck muscles.

November 20. Tremor has extended to muscles of right arm. Knee jerks brisk.

November 21. Flaccid paralysis of legs, back and right arm. Left arm weak and tremulous. Killed with ether. Small cyst containing clear fluid at the point of inoculation. Microscopic sections showed characteristic lesions of experimental poliomyelitis.

EXPERIMENT 4.—*A monkey previously injected intravenously with a streptococcus from the teeth of a monkey which did not have typical lesions of poliomyelitis was not immune to test virus*.—Monkey 21. *M. rhesus*, 2.2 kg.

Previous Inoculation, Sept. 16, 1916.—Injected intravenously with [illegible] c.c. of a suspension in physiologic sodium chlorid solution of the centrifugal growth from 60 c.c. of ascites dextrose broth culture of pus around the teeth of Monkey 18, Case [illegible]6. This organism appeared in smears from broth as a somewhat elongated diplococcus, occasionally in short chains, and on blood agar plate as small dry green-producing colonies. (Monkey 18 was a domesticated monkey with marked pyorrhea alveolaris. He became spontaneously paralyzed in the animal room. When muscle power began to come back he was killed with ether. Microscopic sections did not show lesions of poliomyelitis.)

September 17. Sick and irritable.

September 21. Appeared well. Etherized. Injected into frontal lobe 1.5 c.c. of physiologic sodium chlorid solution containing the growth from 20 c.c. of ascites dextrose broth culture [illegible]6.3 (Monkey 18, teeth). This was a second subculture of the culture injected September 16.

November 2. Had remained well. Blood for serum removed from saphenous vein (compare Monkey 27).

November [illegible]. Etherized. One c.c. of Virus 721 injected into left frontal lobe.

November 19 (sixteenth day). Irritable and tremulous, with weakness of legs.

November 20. Flaccid paralysis of both legs. Wrist drop on right.

November 26. Right arm and back muscles gone. Left arm weak and ataxic but could be used to take food. Good appetite.

December [illegible]. Improving; able to sit up. Arms were stronger but markedly ataxic. Legs could be moved a little.

December 1[illegible]. Got about quite well. Legs paretic and began to show contractures.

EXPERIMENT 5.—*A monkey injected intracerebrally with filtrate of brain and cord of a monkey which did not have typical lesions of poliomyelitis was not immune to test virus*.—Monkey 2[illegible]. *M. rhesus*, [illegible] kg.

Previous Inoculation, Oct. [illegible].—Etherized. One and one-tenth c.c. of Berkefeld N filtrate of Virus [illegible] (glycerinated brain and cord of Monkey 16) injected into left frontal lobe. (Monkey 16 was inoculated with a filtrate of mixed human and monkey virus and developed muscular weakness, but microscopic sections did not give the picture of experimental poliomyelitis.)

November [illegible]. Had remained well. Etherized. One c.c. of Virus 721 injected into left frontal lobe.

November 10 (seventh day). Irritable, with rapid tremor of neck and shoulder muscles. Internal squint apparently due to weakness of right sixth nerve. General muscular weakness.

November 1[illegible]. Markedly ataxic. Left arm awkward.

November 1[illegible]. Less tremor. Both arms weak, especially the right, which showed complete wrist drop. Right leg tired quickly. No knee jerk on right. Strabismus less marked. Photophobia.

November 26. Improving. Shaky and weak; took food well.

December 15. Very active; showed only some residual weakness of right arm, slight internal strabismus and photophobia.

EXPERIMENT 6.—*Example of apparent immunity conferred by inoculation with filtrate and virus seven weeks previously without evident infection*.—Monkey 17. *M. rhesus*, 2.5 kg.

Previous Inoculation, September 1.—Etherized. Injected into frontal lobe 1.5 c.c. of Virus [illegible] (compare Monkey 24) which had been passed through a dense porcelain filter.

September 19. Had remained well. Etherized. Seventy-three hundredths c.c. of fresh human Virus [illegible] injected into frontal lobe.

November [illegible]. Had remained well. Etherized. One c.c. of Virus 721 injected into left frontal lobe.

RESULTS OF TEST INJECTIONS OF A VIRULENT VIRUS

	1 Monkey 23 M. rhesus 2.6 kg. December 15 Had continued to be perfectly normal

Experiment 7—*Example of apparent immunity conferred by inoculation with virus from two monkeys which were paralyzed with virus and culture from a paralyzed rabbit* Monkey 14, *M rhesus* 2 1 kg

Previous Inoculation September 11—Etherized One and five tenths c c of a Berkefeld filtrate of fresh emulsion of brain of Monkey 19 (see below) injected into frontal lobe

September 18 Right arm used rather *awkwardly No other symptoms*

September 20 Well no weakness of right arm detected Etherized One c c of emulsion of glycerinated brain and cord of Monkeys 10 and 12 injected into frontal lobe (Monkey 10 received an intracerebral injection of an emulsion of brain of Rabbit 1017 Monkey 12[1] was twice injected intravenously with a pure culture of streptococci grown from the brain of Rabbit 1017 This was the third of a series of rabbits in which a strain of streptococcus recovered from a human poliomyelitis brain caused flaccid paralysis Both monkeys came down with flaccid paralysis and microscopic sections showed marked cord lesions, without, however the perivascular infiltration which is considered typical of experimental poliomyelitis in monkeys)

November 3 Had remained well Etherized One c c of Virus 751[3] injected into left frontal lobe

November 17 No symptoms

December 15 Had remained well

Experiment 8—*Example of apparent immunity conferred by intracerebral injection of a culture of streptococci isolated from a human cord*—Monkey 19 *M rhesus* 2 8 kg

Previous Inoculation September 16—Etherized One and five tenths c c of suspension of Culture 707 2 injected into frontal lobe (This strain came from a single colony of pleomorphic streptococci 2 cm from the top of a four day ascites dextrose agar shake culture of an emulsion of fresh human poliomyelitis spinal cord This colony was subcultured in tubes and bottles of ascites fluid plus sterile rabbit kidney and ascites broth plus sterile kidney September 16 these subcultures had been growing twenty three days and smears showed an extremely pleomorphic organism lanceolate diplococci, round cocci in short chains, flat sided meningococcus like diplococci and very small globoid chains Chains could be found in which each of these types were present On aerobic blood agar plate these cultures grew pure as fine dry green producing colonies)

September 17 Sick since injection quiet would not eat No muscular weakness

September 18 Better began to eat Arms and legs strong, reflexes normal

October 2 Had remained well

November 2 Had remained well Blood removed from saphenous vein

November 3 Etherized One c c of Virus 751 injected into left frontal lobe

December 15 Daily observations had shown no abnormality

COMMENT

Three unused and five used monkeys were injected with a monkey virus The test virus had been carried through monkeys to a stage of virulence at which it should, according to the experience of investigators, cause experimental poliomyelitis in all nonimmune monkeys injected The two control monkeys became severely paralyzed and were killed The third (Monkey 37) also became a good control, as the experiment proved that the animal from which 70 per cent of the serum was obtained (Monkey 21) was not an immune monkey

Monkeys 21 and 24, which came down with typical poliomyelitis symptoms and recovered, are of considerable interest in that they show that inoculation with cultures or filtrate of virus from nonpoliomyelitis sources, as determined by pathologic findings, does not confer immunity to a virulent virus

There remain the three monkeys which showed no symptoms following the test injection and were normal forty-five days after The question whether or not these animals showed any symptoms of infection after their previous inoculation is difficult to determine Monkey 14 had a definitely clumsy right arm for about twenty-four hours at a period seven days after his first injection, but no weakness could be made out His awkwardness rapidly disappeared, and he showed *none of the usual symptoms of irritability and tremor* No symptoms were observed in the other two monkeys

The important point of the experiment is that two of the three monkeys which were not affected by the test virus had previously been injected with material obtained from cultures of human poliomyelitis nervous tissue Monkey 14 received filtrate and emulsion of brain and cord of monkeys which had been paralyzed with rabbit virus and culture, the successive passages of this strain through three rabbits in the form of large lanceolate diplococci grown aerobically would seem to exclude any possibility that the small anaerobic organism described by Flexner and Noguchi could have been carried over Similarly, the culture used in Monkey 19 came from a single colony near the top of an agar shake culture Flexner and Noguchi[2] state that they have never obtained from poliomyelitic material *in solid medium an initial* growth of the small organism, aside from contaminations

We wish to record these observations as suggestive of the importance of immunologic studies with the pleomorphic streptococcus which has been isolated from the central nervous system in cases of human and experimental poliomyelitis

END-RESULTS OF THE TREATMENT OF TUBERCULOSIS OF THE SPINE, HIP, KNEE AND ANKLE JOINTS

FROM THE RECORDS OF THE NEW YORK ORTHOPEDIC DISPENSARY AND HOSPITAL

ROBERT E HUMPHRIES, M D
Surgeon in Chief, New Jersey Orthopedic Hospital Assistant Surgeon New York Orthopedic Hospital

AND

H A DURHAM M D
Assistant Surgeon New York Orthopedic Hospital Surgeon New York Orthopedic Dispensary

NEW YORK

During the past twenty years treatment of joint tuberculosis at the New York Orthopedic Dispensary and Hospital has been for the most part conservative, the main object being to procure as near as possible immobilization of the diseased joints

Weight bearing has been considered advantageous when it did not interfere with fixation, as in the knee and ankle joints, but of considerable disadvantage when it did interfere with fixation, as in the hip and spine

Ankle joint disease has been treated by fixation with a stiff ankle brace having a molded foot piece which fits inside the shoe, plaster having been used as temporary dressing only The use of crutches has been necessary at times when the disease has been too acute to permit of weight-bearing

In the treatment of knee joint disease a stiff leg support has been used, this is fastened to the shoe and extends to the groin, with a leather backing extending from the thigh band to the calf band, thus forming a trough in which the leg is firmly held by a muslin bandage, extending from the middle of the calf to the top of the brace The bandage is changed daily, thus assuring constant fixation, and ready accessibility to inspection by the surgeon The only exception to this rule has been in those cases with marked flexion deformity This has been reduced with a plaster cast supplemented by traction, the cast being changed weekly

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit June, 1916

TABLE 1—ANKLE JOINT DISEASE

Total number of cases of ankle joint disease treated	50
Number of boys treated	28
Number of girls treated	22
Number of cases with right ankle involved	31
Number of cases with left ankle involved	19
Average age on admission, years	5½
Duration of disease on admission months	7½
Average duration of treatment years	4½
Number patients cured	23
Number under treatment at present time	0
Number died	6
Number could not be located	21
Of the patients cured number with free motion with no deformity of foot	15
Number with limited motion with no deformity of foot	6
Number with limited motion and deformity of foot	2

The management of hip joint disease brings other factors into consideration Owing to the conformation of this joint, it is difficult under any circumstances to eliminate all motion This is at once rendered impossible when weight-bearing is allowed The Taylor hip splint has been used almost exclusively for this condition, since it eliminates weight-bearing by its crutch action While the traction on the thigh supplied by this apparatus does not separate the joint surfaces, as was formerly supposed, it does render valuable aid to joint immobilization

Up to the year of 1910 the Taylor spinal assistant was used entirely in the treatment of Pott's disease It is easy to apply, can be accurately adjusted, is not liable to cause excoriation, is sanitary and renders the spine constantly accessible for inspection by the surgeon In spite of the careful treatment given each patient, it has been impossible to prevent increase of deformity in a large percentage of cases This is especially true when the disease involves the dorsal region, because owing to the movement of the thorax during respiration, no form of apparatus yet devised is capable of accurately fixing this area It is true that in some cases of cervical and lumbar disease deformity can be prevented by mechanical apparatus

TABLE 2—KNEE JOINT DISEASE

Total number of cases of knee joint disease treated	156
Number of boys treated	87
Number of girls treated	69
Number of cases with right knee involved	83
Number of cases with left knee involved	73
Average age on admission years	6½
Average duration of disease on admission year	2
Average duration of treatment years	7
Number patients cured	106
Number under treatment at present time	7
Number died	7
Number could not be located	43
Of the patients cured number with lengthening of limb	10
Number with no change in length of limb	73
Number with less than 1 inch shortening	7
Number with less than 2 inches shortening	14
Number with more than 2 inches shortening	2
Number with flexion deformity without ankylosis	5
Number with flexion deformity with ankylosis	13
Number with ankylosis without deformity	13
Number with fifteen to ninety degrees flexion from full extension	36
Number with more than 90 degrees flexion from full extension	39

Because of the inability accurately to fix the spine, and thus prevent deformity, it occurred to Dr Hibbs that it might be possible by operative procedure to produce a fusion over the posterior aspect of the diseased and adjacent vertebrae, thus eliminating motion, limiting deformity, and giving nature a better opportunity of combating the disease

With this end in view, the first osteoplastic operation on the spine was performed Jan 9, 1911 The results obtained in those patients operated on in the early part of 1911 were so gratifying that for the past four years operation has been advised as a routine in all cases except those in which complication rendered the prognosis hopeless This treatment has been supplemented by a spinal assistant worn from six to eighteen months after operation Operative treatment is particularly advantageous in early cases, as it offers a means of limiting deformity and shortening duration of treatment

The accompanying tables report only those cases of joint tuberculosis in which the patients were under 16 years of age at the time treatment was begun, who came to the dispensary between the years of 1895 and 1910, and whose treatment was continued two or more years

TABLE 3—HIP JOINT DISEASE

Total number of cases of hip joint disease treated	461
Number of boys treated	236
Number of girls treated	225
Number of cases with right hip involved	242
Number of cases with left hip involved	219
Average duration of disease on admission years	2
Average age on admission, years	7
Average duration of treatment years	7½
Number patients cured	171
Number under treatment at present time	44
Number died	60
Number could not be located	215
Of cases cured number with less than 1 inch shortening	40
Number with less than 2 inches shortening	59
Number with less than 3 inches shortening	60
Number with more than 3 inches shortening	21
Number with adduction and flexion deformity combined	36
Number with flexion without adduction deformity	17
Number with bony ankylosis	13
Number with fibrous ankylosis	49
Number with no destruction of femoral head (Roentgen examination)	32
Number with partial destruction of femoral head (Roentgen examination)	86
Number with complete destruction of femoral head (Roentgen examination)	88
Number with partial acetabular destruction but no evidence of disease of femoral head (Roentgen examination)	6
Number with dislocation (Roentgen examination)	3
Number with thigh flexion from 15 to 90 degrees	73
Number with more than 90 degrees thigh flexion	45
Number with perfect function without deformity	35
Number with relaxation of knee joint	20

CONCLUSIONS

From the foregoing statistics it would seem that the following conclusions are justified

1 The regions most frequently involved in joint tuberculosis in order of frequency are the spine, hip joint, knee joint and ankle joint

2 The disease is more frequent in boys than in girls

TABLE 4—POTT'S DISEASE

Total number of cases of Pott's disease treated	517
Number of boys treated	284
Number of girls treated	233
Location of disease Cervical	47
Upper dorsal	71
Middorsal	118
Lower dorsal	105
Dorsal lumbar	100
Lumbar	76
Average age on admission years	5¼
Average duration of disease on admission years	1½
Average duration of treatment years	7½
Number patients cured	125
Number under treatment at present time	7
Number died	112
Number could not be located	227
Of the patients cured number with marked increase in deformity	50
Number with slight increase in deformity	42
Number with no increase in deformity	28
Number with no deformity	5
Number of patients operated on	48
Number of patients not operated on	77
Number of cases in which deformity increased, following operation	10
Number of cases in which deformity did not increase after operation	38

3 The disease affects the joints of the right side more frequently than those of the left

4 The average duration of treatment of all joint disease patients was six and one-half years

5 Joint tuberculosis is usually well advanced before diagnosis is made, the average duration of the disease on admission being one and one-half years

6 The average age of patients when admitted for treatment was six and one-fourth years

7 Ankle joint disease can be cured in most instances with little or no deformity

8 Of the knee joint cases seen, 15 per cent had more than 1 inch shortening, 25 per cent had ankylosis, 75 per cent. had more than 15 degrees motion from full extension, 38 per cent had more than 90 degrees motion from full extension

9 Of the hip joint cases cured, 34 per cent had less than 1 inch shortening, 24 per cent had varying degrees of flexion and adduction deformity, 28 per cent had bony or fibrous ankylosis, 55 per cent. had none or only partial destruction of the heads of the femora, 55 per cent had more than 15 degrees flexion from full extension, 9 per cent had some degrees of relaxation of knee joint

10 In Pott's disease the dorsal region is much more frequently involved than all the other regions combined, 73 per cent of all cases of Pott's disease had perceptible increase of deformity during the course of treatment

Of the patients operated on, 20 per cent had some increase in deformity following the operation but in no case was there actual increase in deformity of the area operated on

104 East Fortieth Street—2 West Sixty-Fifth Street

ABSTRACT OF DISCUSSION

Dr John Ridlon Chicago The results of this work are remarkably good Of the twenty-three cases of ankle joint disease cured, fifteen had free motion, with no deformity of the foot It has been a belief of mine for many years that ankle-joint disease is the most favorable kind of chronic tuberculous joint disease we have to handle I have seen a tuberculous ankle joint go through several years of disease, have abscesses and sinuses develop, and go on to spontaneous opening and healing, without having been treated or having been seen by a doctor during the course of the disease recovery taking place without deformity and with almost a normal range of motion This may be the explanation why such remarkably large and good results followed in the cases of the disease reported in the paper In the knee-joint disease, there were eleven in which there was actual lengthening of the limb I have seen this in only one or two, or two or three cases, perhaps, and it is my conviction that these are the cases in which the knee joint disease is a syphilitic inherited disease and in which the disease is located, not within the joint itself, but at the epiphyseal line of the femur, as was the case in such instances of lengthening as I have seen There were five that had flexion deformity without ankylosis and thirteen that had flexion deformity with ankylosis at the knee joint I believe that if we can control our cases, we ought to be able to cure all without flexion deformity Of the hip-joint patients, 171 were cured

Only thirty-six had adduction and flexion deformity and seventeen had flexion deformity without adduction deformity, making a total of fifty-three treated by the long traction hip splint of Taylor I have used that splint all my life, and have never been able to get anything like such good results from it I am amazed that such a large proportion can be cured without adduction deformity It shows the careful attention that the patients have had, and is a wonderful result Eighty-eight had complete destruction of the femoral head, and only a partial acetabular destruction My experience, when I have had the advantage of Roentgen-ray examination, is that I have found a larger number showing destruction of the acetabulum than of the head, and unless these have all been carefully checked up and the sockets compared with the sockets on the other side by Roentgen-ray examination, I should doubt that result Of the 171 patients, 153 were cured without motion These are beautiful results, and show how absurd is Lorenz position that patients should be treated to secure ankylosis as soon as possible, and that it is impossible to cure these patients with motion We know it is possible to get a large number of patients cured with motion, and here are the results Twenty were found, after cure, with relaxation of the knee joint That has been one of the unpleasant results that I have had from the use of the long traction splint, and I have ceased to use it as soon as I find the knee joint begins to be lax I have used it in the past longer and in more cases than necessary, and I believe that we should have obtained as good motion and less deformity, with no relaxation of the knee joint, if we had discontinued its use and put the patients in some form of immobilizing apparatus, allowing them to walk on these limbs

Dr Reginald H Sayre, New York The institution is to be congratulated on the results shown in the paper, but the statistics do not give very much information Here are sixty-three patients getting well of hip disease with flexion and adduction deformity, but there is nothing to show how much of that was due to faulty care in the institution, and how much to inattention on the part of the parents and their lack of taking care of the children as they should There is nothing in the statistics to show how much deformity the patients had when they came under observation, as compared with what they had when they went out from under observation This is true of the statistics of most of our institutions I feel somewhat as Dr Ridlon does regarding the difficulty of preventing flexion deformity in the hip by means of the hip splint with simply a pelvic belt For years I have been using a thorax belt, as well, and since I have adopted this, the patients have not had flexion deformity, if there was regularity in the attendance of the patient I think that Dr Phelps was right in his contention that we should make the splints as nearly fool-proof as possible in dispensaries, and also in private practice In regard to the relaxed knees, I believe that they are caused by our own inattention, and that we often pull on the shin instead of on the thigh Frequently, when the patients legs itch, they pull the plaster off the thigh, and we pull on the shin, instead of the thigh, without noticing it Berkley Hill of London about forty years ago drew my father s attention to the possibility of doing that, and getting relaxed knees in the treatment of hip diseases by the Sayre splint My father said, "You get relaxation of the knee joint from it, because you pull on the shin, instead of on the thigh' That is the trouble in many of the relaxed knee joint cases This report distinctly shows that ankylosis is not the thing to be desired in joint disease I believe that the nearer you get to a normal joint, the more desirable the result will be That is not the German idea, and I know that some of my American friends think that you should strive for ankylosis of these joints I know, however, that I can frequently obtain movable joints, and as long as I can do so, I will follow the efforts to get them

Dr Charles M Jacobs, Chicago I should like to have Dr Humphries tell us whether he uses only long traction hip splints in all his hip cases, and if not, what are his results with the use of the plaster casts

Dr Robert E Humphries, New York Dr Ridlon says that he has found a greater percentage of cases with acetabular destruction than this report indicates The cases considered in this report as having had acetabular destruction showed no evidence of disease in the head of the femur on Roentgen ray examination Many cases showed destruction of both the head of the femur and the acetabulum and are therefore only considered under the heading of destruction of the head of the femur The good results obtained were due mainly to two factors first, a large outpatient nursing staff which keeps in constant touch with the patient, instructing the parents in the adjustment of braces and in the hygienic care of their children and also seeing that the patients are brought regularly to the dispensary, second, a country hospital where many of the cases reported were treated Patients with joint tuberculosis cannot be cared for properly at home without frequent visits by nurses and they can be taken care of very much better in a country hospital devoted solely to the treatment of joint tuberculosis The point advanced by Dr Sayre, that statistics are always inaccurate because one cannot tell what percentage of poor results are due to inefficiency on the part of the surgeon and what is due to the neglect by the parents, is a good one, however, I do not see how this can be ruled out Plaster of paris is never used except as a temporary dressing consequently it is impossible at this time to compare this form of treatment with that of plaster

A PRIMIPARA AT 46

SEELEY ANDREWS, M D MINDEN NEB

The patient, a blonde, small boned normal weight 115 pounds, was born in Denmark June 17, 1870 She was a domestic until ten years ago then clerked in a store, and was married two years ago Her last menstruation occurred Feb 1, 1916 Pregnancy was uninterrupted except for threatened miscarriages in June and September 1916 when she had several pains and a good deal of hemorrhage Since the fourth month she had considerable albuminuria and the blood pressure had constantly been above 150 She had had dropsical conditions of the lower limbs and violent headaches at times

Two days before confinement I examined the patient, and found her in normal condition except for a funnel-shaped pelvis with a diameter of 8 cm The coccyx was movable and could be pushed well back Pains began at 12 p m, November 16, labor terminated at 9 p m November 17 Preparations were made for cesarean section because of conclusions from the prior examination Labor was normal, the head engaged and then delivery was accomplished after the medium forceps operation There was a slight laceration which was repaired at the time

I have been unable to find in the literature a record of a patient anywhere near this age at first confinement

DISTURBANCES OF THE KIDNEYS

(Continued from page 199)

RENAL CALCULI

Renal calculi vary from small particles of precipitated salts—enough to make a granular sediment in the urine passed without pain or knowledge, to concretions large enough to cause colics, or to remain in the pelvis of the kidney Although it was thought that uric acid stones were very frequently found in the urine and that calcium oxalate stones seldom appeared, it has been shown recently that the latter occur most frequently, and form the largest element in the composition of renal calculi It has been shown also that these calcium oxalate calculi are not necessarily hard[59] As uric acid calculi may be very hard, and calcium oxalate calculi may be soft, Rowlands believes that the hardness of calculi depends on the rapidity of their formation — the slower the formation the harder the calculus

Most renal calculi contain uric acid or urates in small amounts However, these ingredients can be determined only by chemical analysis, as one cannot decide the character of a calculus from its color, shape and hardness Renal calculi may occur with or without gout, that is, gout and the formation of calculi are not closely related, according to Kahn The tophi in gout may be composed of sodium and ammonium biurate or possibly of calcium oxalate It is by no means to be taken for granted that they always contain uric acid or urates

Phosphatic calculi frequently have a uric acid nucleus Theoretically calcium oxalate and uric acid calculi should not be redissolved in the kidney or bladder after having once been formed, nevertheless, urate and phosphate deposits evidently do dissolve or break down repeatedly However, it has recently been shown by Haskins[60] that all neutral, alkaline or slightly acid urines will absorb uric acid, that the less acid the urine the more uric acid will generally be dissolved, and that a dilute urine will usually dissolve more uric acid than a concentrated urine Therefore, a freshly formed uric acid concretion may dissolve in the kidney or bladder, provided the urine is not too acid or too concentrated

The phosphate calculi are usually mixtures of ammoniomagnesium phosphate and calcium phosphate Calcium carbonate is rarely found, xanthin and cystin deposits occasionally occur Some irritation in the pelvis of the kidney is generally the primary cause of this deposit, a mucous shred or a clump of bacteria with its surrounding leukocytes forming a nucleus

SYMPTOMS

While patients can pass a large amount of gravel with little pain, the presence of these crystals in the urine is frequently accompanied by backache or pains shooting down the ureters, irritability of the bladder, and occasionally urethral stinging from the urine If a calculus is present in the pelvis of the kidney, repeated examinations of the urine and of the centrifuged portions will usually prove that there are more red blood corpuscles than normal The urine may show macroscopic blood and shreds of mucus streaked with blood Of course, blood in the urine does not prove that a calculus is the cause, but with other symptoms of calculi, with pain referred to one side, with ureteral catheterization showing blood coming from one kidney, and with the positive evidence of a roentgenogram, the diagnosis can be made It should, of course, be recognized that kidney pain and even kidney colic may not be caused by a calculus impinged in the orifice of the ureter The cause of this usually intermittent pain may be discovered by deduction or by the examinations just suggested

Sometimes this kidney pain is not referred to the back, but to the center of the abdomen, upward toward the liver, to the right side, or to the appendix region If the calculus has entered the ureter, the pain is referred down its length toward the bladder, soon pain is felt in the testicles in the male, and in the vulva in the female, and later, in the male, there is pain referred to the end of the penis It should be noted that renal calculi occur more frequently in men than in women

Besides blood albumin may occur in the urine, and hyaline casts may be found, owing to reflex irritation caused by the calculus If the pelvic irritation continues, inflammation may result with increased mucous secretion, followed by pus

Generally careful palpation of the suspected kidney will show that it is tender to pressure, it may be enlarged

A true renal colic comes on suddenly, often without previous symptoms, and is as likely to occur when the patient is in bed as when he is undergoing physical exertion In about half of the cases, pain starts in the lumbar region of the affected side comes gradually around toward the abdomen, and shoots down toward the bladder, as described The pain is generally accompanied by nausea and vomiting, a feeling of faintness, and a weak pulse Sometimes the skin is covered with cold, clammy perspiration, and the patient is on the verge of collapse At times the patient lies down with his pain, sometimes he is bent over with pain, and sometimes he writhes in agony There is often a desire to urinate frequently, sometimes without the ability to do so The temperature seldom rises Blood may pass into the bladder, the urine becoming discolored even before the calculus has passed When the calculus reaches the bladder, the cessation of pain is almost instantaneous During its passage down the ureter the patient is generally aware of its location, the pain leaving the back and being referred more and more toward the bladder and down into the genitals

[59] Rowlands Biochem Jour 1908 3, 346 Mackarill Moore and Thomas Biochem Jour 1910 5 161 Kahn Max Study of the Chemistry of Renal Calculi Arch Int Med January 1913 p 92

[60] Haskins Jour Biol Chem August 1916

As soon as it has been determined that the calculus has reached the bladder, the patient is told to hold the urine for a while and then pass it as rapidly as possible from the urethra, so as to flood out the calculus from the bladder Until the calculus is found the urine should be passed either into a jar or through a strainer, and neither physician nor patient should be content until the calculus is found, or until it has been decided that the calculus has disintegrated somewhere during its passage Such a disintegration often occurs if the calculus has been rapidly formed and is soft, especially if it is of the urate variety

Recurrent attacks of renal pain, and often apparently ureteral pain, may occur without the passage of a calculus Such attacks are often accompanied by fever, and may be preceded by a chill If the pain is not very severe, it may be termed a backache, and the patient be told that he has malarial intermittent fever It is inexcusable, however, for such a diagnosis to be made, as the malarial element can be excluded by examination of the blood, and a careful examination of the urine, localization of the symptoms and roentgenoscopy should make the diagnosis conclusive In these instances not only does a large amount of mucus appear in the urine, but soon small amounts of pus are apt to appear, with signs and symptoms later of actual inflammation of the pelvis of the kidney

TREATMENT

The immediate treatment is the same as that of colic of the kidney The pain must be stopped and the tissues relaxed if possible No manipulations of the kidney or urethra should be attempted, as this will do more harm than good The patient should receive a hypodermic injection of ¼ grain of morphin with ¹⁄₁₀₀ grain of atropin, and, if possible, should sit in a bathtub filled with warm water up to his waist The relaxation caused by the water may stop spasm and aid the passage of the calculus Of course if the pain is intense and he is faint and vomits, or if the pain persists for an extended period of time, such bath treatment is impossible and inadvisable Under such conditions, hot, moist fomentations over the affected side will afford some relief

If the morphin has no effect within from a half to three quarters of an hour, another injection must be given, the character of the pain and the size of the person determining the dosage Another ¼ grain or ⅙ grain of morphin should be given, not combined with atropin, as it is unwise to repeat the dose of atropin Atropin acts slowly and persistently, and a large dose may cause stimulation of the heart and central nervous system instead of sedation of the peripheral nerves If the patient has been seen previously and is known to be very tolerant to morphin, the first dose may be much larger than the ¼ grain advised, large doses of morphin should not be given, however, since as soon as the calculus is either forced back into the pelvis of the kidney, or passes into the bladder, the intense pain immediately ceases, and the whole activity of the morphin is in evidence In fact, whenever large doses of morphin have been administered for acute pain and the pain has ceased, the patient should not be allowed to sleep for some hours, the nurse or attendant keeping him awake until part of the morphin has been eliminated The patient should be encouraged to pass the urine as soon as the bladder is considered full, and large drafts of water should be taken to wash out the stomach Black coffee may also be given to stimulate the nervous system and to counteract the effect of the morphin on the respiratory center, and later, the patient should be given a cathartic to relieve constipation caused by the morphin Food should not be given for some hours

In order to avoid an overdose of morphin, the patient may be given a few whiffs of chloroform to bring about the relaxation desired and to allow the morphin to show its effect. Sometimes the action of chloroform administered after a morphin injection is successful, the pain not recurring with such intensity, and the patient becoming quiet, although he knows that the stone has not passed Much chloroform should not be given, nor should it be given too frequently, as cardiac debility may be caused by the repeated use of even small inhalations No other drugs are of any assistance whatever in the treatment of renal colic

After-Treatment.—The calculus should be examined in order to discover its component parts, as its constituency may indicate the character of the food to be avoided It should be remembered that at the time of the deposit of one calculus there may have been others, and prophylactic measures should be taken, as other colics may occur The patient should drink large amounts of distilled water, or, if the urine shows high acidity, particularly if the calculus was found to be of the uric acid variety, he should be given alkalies and large amounts of sodium bicarbonate or good sized doses of potassium citrate The frequency and size of the dose depends on how much it takes to cause the urine to become alkaline On the other hand, if the calculus was found to be phosphatic and the urine only faintly acid, or alkaline, alkalies should not be given but rather something to make the urine acid—as hexamethylenamin or dilute hydrochloric acid—to be taken after meals

The diet depends on the character of the concretion and the condition of the urine Meat should for a time be avoided, provided the urine is highly acid and the calculus was composed of uric acid, calcium oxalate or urates If the urine is alkaline and the calculus was composed of alkaline salts, meat should be allowed Ordinarily, a milk and cereal diet is proper, the diet depending more or less on the amount of intestinal indigestion caused Such indigestion is to be guarded against both by the administration of laxatives and by arrangement of the diet, as the formation and absorption of by-products or toxins, and the presence of indicanuria have a tendency to cause more urinary deposits Needless to say, alcohol, excessive tea and coffee drinking, rich foods and fancy dishes should be prohibited Pure water is of great importime, and the patient should drink it liberally unless some affection of the heart or kidneys compels him to drink it in moderate quantities There is no artificial water, no mineral water, no lithia water which will dissolve as much salts as will distilled or ordinary pure water Consequently, nothing is attained by buying expensive bottled waters

In the presence of the conditions that cause urinary concretions, it is self-evident that a sojourn at some mineral spring, "cure" or sanatorium at which the diet, the exercise, and the hours of sleep and rest are all under supervision, will benefit such patients but let it be emphasized that it has not been proved that lithia waters will dissolve renal or gallbladder calculi, while lithia in almost any form, in any tangible amount, tends to cause gastro-intestinal indigestion

The subject of urinary solvents has recently been reviewed by Haskins,[61] whose findings may be thus summarized Piperazin may cause the urine to dissolve more uric acid, which may be further increased by giving with it sodium citrate or bicarbonate The best results occur when diuresis is not caused Lysidin increases the uric acid solution, but is not a very good agent, as large doses are required Lithium carbonate is of value only in large and dangerous doses, and is no better than sodium citrate or bicarbonate, in fact, sodium citrate, sodium bicarbonate or potassium citrate are very satisfactory uric acid solvents when given in sufficient doses to alkalize the urine In other words there is no necessity for administering any but these last three well known, simple drugs, especially when combined with the use of distilled or pure water

Unless it is desired to increase the uric acid excretion it is not advisable to administer atophan or novatophan in cases with calculi If it seems advisable to give these drugs, they should be combined with sodium bicarbonate and given in small doses, such as 0 3 gm (5 grains) two or three times a day Large doses of atophan may cause gravel, and sometimes colic

Normal urine should be acid, and to keep it alkaline for any length of time is generally bad treatment Therefore alkalies should not be administered over an extended period of time as such procedure may result in cystitis, pyelitis or possibly the precipitation of phosphate calculi Furthermore, any bacteria that may be lodged in the pelvis of the kidney or in the bladder, caused by the irritation of the previous calculus, will grow more rapidly in this alkaline medium

If before or after the passage of calculus, or while a calculus is suspected or known to be located in the pelvis of the kidney, the urine is alkaline or ammoniacal without treatment, hexamethylenamin and dilute hydrochloric acid should be given as suggested above If there is no marked bleeding from the kidneys or in the urine, the dose of hexamethylenamin should be 0 3 gm (5 grains), dissolved in half a glass of water, four or five times a day, or 0 6 gm (10 grains) in a glass of water, three times a day, for one or two weeks, the treatment should then be suspended, and perhaps later begun again Very large doses of hexamethylenamin are not necessary If the urine nevertheless remains alkaline, the hexamethylenamin is of no value, and one may conclude that the inflammation is serious, probably requiring surgical interference With many bacteria in the urine the hexamethylenamin treatment is the correct one Alkalies should not be given

In some instances the pain is referred to the region of the gallbladder, in others, particularly in colic of the right side, to the appendix Diagnosis in these cases is difficult, especially when not accompanied by hematuria

Therefore, before operative interference is decided on for possible appendicitis or gallbladder trouble, roentgenograms should be made It should be noted that not every calculus (even in the bladder) will cast a shadow, also that calcareous deposits in a tuberculous kidney may cast a shadow not unlike calculi When there is doubt, and when the pain is a chronic, one-sided pain, particularly of the right side, cystoscopy and ureteral catheterization should be performed, and in some instances a dilating wax-tipped bougie may be passed into the pelvis of the suspected kidney Pyelography may be utilized for diagnosis as with a stone in the kidney it has been asserted that the pelvis is generally more or less enlarged In acute cases without pus in the urine, and with a suspected appendix inflammation, a blood count showing a leukocytosis should indicate appendicitis When gallbladder inflammation is suspected, there should be increased temperature, probably leukocytosis, staining of tissues with bile — which may also be found in the urine and possibly distinct evidences of jaundice In chronic cases in which there may be a stone in the kidney, and operative interference necessary, not only the foregoing examinations, but also functional tests of the kidneys, and blood tests for nitrogen retention should be made If there has been a calculus in the kidney for some time, the function of that kidney is usually impaired, and there may be pus If the stone is not passed within a month after the renal colic, radiograms of the kidney should be made If no stone is thus located, it may be hoped it has dissolved or become disintegrated, if it is located, it should be surgically removed before the kidney is injured The kind of operation to be performed on a kidney found to harbor a calculus depends on the condition of that kidney, and on the functional ability of the other kidney This will be referred to later under another heading Blood in the urine, more than a few corpuscles which may always be present, points distinctly to a pathologic condition in the urinary tract, and is rarely coincident with appendicitis or gallbladder trouble

(To be continued)

Second Illness Census in Health District No 1—In the November *Bulletin* of the New York City Department of Health appear the results of two illness censuses taken in the experimental health district The first was taken in August 1915 and the second in February 1916 Comparatively few deaths were caused by respiratory diseases but the mortality from these diseases is excessively high in the negro and Italian districts The incidence of illness is higher at the extremes of life and the percentage of increase in illness during the winter months is greater in infancy and old age Up to the fifteenth year males appear to be more susceptible to disease than females, after the fifteenth year the reverse obtains The lowest illness rate was observed among clerks, and is due to their favorable age as well as to their sheltered occupation The family income is an important factor in morbidity and mortality The incidence of illness from all causes was found to decrease as the density per room decreased excepting when a great proportion of elderly persons entered into the calculations The conclusion is reached that these illness censuses have demonstrated the value of such intensive study It is therefore proposed to take a census of illness in those districts of the city in which the mortality is unusually high

INFECTIOUS JAUNDICE — WEIL'S DISEASE — SPIROCHAETOSIS ICTEROHAEMORRHAGICA

In 1886, Weil[1] described the disease which subsequently more or less consistently has been called Weil's disease In case this term has come to include diseases of different etiology, which seems altogether likely, it naturally will require a more exact knowledge of the etiology than we now possess before the diseases in question can be fully and satisfactorily understood The recent discovery both in Japan and Germany of a spirochete as the cause of acute febrile jaundice, believed to correspond fully to what is meant by the term "Weil's disease," marks a long advance in the direction just indicated In Germany Huebener and Reiter,[2] and a few days later Uhlenhuth and Fromme,[3] apparently wholly independently, not long since announced that in guinea-pigs the injection of the blood of patients in the early stages of Weil's disease causes symptoms and changes similar to those of the human disease — fever, jaundice, hemorrhages, albuminuria, degeneration of liver and kidneys, etc The blood and urine of such guinea-pigs are pathogenic and transmit the disease to other guinea-pigs on injection or oral and rectal introduction, but not through the healthy skin The investigators mentioned also found organisms in the blood and organs, especially in the blood and then in the liver, of injected guinea-pigs and of patients with Weil's disease, which Uhlenhuth and Fromme[4] described as delicate, motile spirochetes The first description of Huebener and Reiter was less definite, but subsequently[5] they also regarded the organism as a spirochete and named it *Spirochaeta nodosa* It was found that, as the symptoms subside, specific spirocheticidal substances appear in the blood, and the serum becomes both protective and curative, hence the outlook for the development of a successful serum therapy would seem encouraging Following Ungermann, Reiter[6] announced that the spirochete can be grown on artificial mediums, the best medium being rabbit serum diluted with salt solution and covered with oil to exclude air His efforts to demonstrate by experiment that certain biting insects may transmit the spirochete do not seem to have yielded any decisive results

Turning now to the Japanese work, we find that Inada, Ido and their associates are studying a disease which occurs in various parts of Japan, especially in certain coal mines, and which corresponds in description to the description of Weil's disease, the death rate being about 32 per cent We find also that successful inoculation of guinea-pigs and demonstration of spirochetes were accomplished a year or more before the Germans announced their discoveries The most important results of the Japanese work are available in an English summary[7] which shows that guinea-pigs were inoculated in 1913 and spirochetes found in 1914 Here, too, are reported successful methods for growing the microbes on artificial mediums In human beings the spirochetes are most numerous in the blood on about the fourth and fifth days, and are easily demonstrable in the liver and elsewhere when death occurs early, but inoculation experiments and efforts to demonstrate the organisms in the tissues fail after the twelfth day or so In the urine, however, virulent spirochetes continue to appear much longer, sometimes for from forty to fifty days or more, they are also found sometimes in the sputum and feces Martin and Pettit[8] also have found the urine in Weil's disease infectious The disappearance of spirochetes from the blood and the organs (except possibly the kidneys) is associated with the development of specific antispirochetal substances, the action of which is shown by appropriate tests (Pfeiffer's phenomenon) The Japanese investigators[9] have immunized horses with cultures of the spirochetes and obtained immune serum with definite action, which serum is being tested in the human disease

Whether or not the spirochete described by the German workers is exactly the same as the one described by Inada and his co-workers is hard to say and need not be discussed any further now It is noteworthy that the main results of this highly interesting work in the two far separated countries on what for short we call Weil's disease correspond closely — demonstration of spirochetes in the blood and tissues of patients, demonstration of the production in guinea-pigs of a condition like the human disease with the presence of spirochetes by the injection of infectious blood, and demonstration of an antispirochetal immunity The results of the Japanese investigations, which are the earlier and the more complete, differ from the German in that they show rats and mice to be susceptible, and this is a point which should be carefully studied in the future, especially because, in a recent article by Ido[10] and others, evidence is brought forward that both house and what they call brown or ditch rats may harbor virulent spirochetes in their kidneys and thus play an important part in spreading the disease The Japanese also assert that in guinea-pigs the spirochetes may enter through the unbroken skin Finally, it may be pointed out that in the event the spirochetes described in Japan and in Germany as the cause of icteric infections — spirochaetosis icterohaemorrhagica (Inada)—prove to be the same, the name proposed by the Japanese, *Spirochaeta icterohaemorrhagiae* by virtue of priority, will replace *Spirochaeta nodosa,* suggested by Huebener and Reiter The further developments from the study of icteric infections by the methods just discussed may be awaited with much interest

FOOD FAT AND MILK FAT

So long as Virchow looked on both the fat globules and other constituents of milk as the direct products of a fatty degeneration or disintegration of the cells of the mammary gland, there was little consideration of the possible interrelations of the food fats and those which appeared in the mammary secretion Later, when pathologists like Arnold of Heidelberg concluded that even the freest secretion of milk may take place without any degeneration of the cells of the mammary glands, no emphasis was given to the direct interdependence of food and milk fats It was believed at that time that the components of the fat are brought to the lactating cells from without in a water-soluble form, and that the fat is newly constructed from such material within the cellular protoplasm by functioning vital processes

There can be no doubt today that various ingested substances — for example, drugs — may pass as such into the milk Intoxication of infants through poisonous substances taken by the mother and transferred into her milk are not unknown For the most part, however, these are accidental constituents of milk, and represent distinctly foreign substances If they are fairly soluble they are likely to travel to all of the tissues and secretions before they can be completely eliminated by the parent organism The appearance of such traces of foreign derivatives in milk, therefore, is presumably largely fortuitous rather than due to a special selective secretory activity on the part of the glands producing it

The problem of the appearance of the fats of the food in the fat of the milk offers somewhat different aspects from the foregoing, in view of the fact that fats in general are not essentially "foreign" to milk Here again, however, prevailing views of metabolism have influenced the decision as to the transport of food fat So long as it was believed that fats are absorbed as such and carried in the circulation in the form of emulsified particles to various regions of the body, there was no obvious limitation to a rather direct transfer of fat from food to milk It was in this belief that investigations with a large number of fats not characteristic of the lactating animal were made The feeding of such extraneous fats as cottonseed oil, sunflower oil, peanut oil, cocoa butter, linseed oil, sesame oil, almond oil, palm oil, etc, seemed to remove all doubt of their transfer in part into the milk

Latterly several circumstances have served to present the question of the origin of milk fats in a still different light The demonstration of the actual digestion of ingested fats prior to their distribution and utilization in the body is now generally accepted Fats are not absorbed unchanged, though they may be reconverted to their original form after passage out of the alimentary canal The conviction that lipoids such as lecithin and cholesterol may play a significant part in the metabolism of the fats has gained ground, especially through the studies of Bloor[1] But in addition to this, account must now be taken of the growing belief that we must distinguish between cell fat and stored fat, such as is found in the fat depots of the body Leathes and his collaborators, in particular, are largely responsible for the doctrine that the fatty acids derived either from the foods or from the stores in the body are prepared, so to speak, for metabolism by a preliminary chemical change in the liver Here mobilized fat, like fat absorbed from the intestine is, in the first instance, said to be altered so that it is composed to a much larger extent of unsaturated fatty acids This "desaturation" of fatty acids is believed to produce new fats which offer less resistance to the combustion processes which furnish energy to the organism The unsaturated unions are the weak links in the carbon chains of the fatty acids, and form the presumable points of attack in the catabolic disintegration of the fats Thus fat from the connective tissues where it is stored differs from that which has passed through the liver as a preparation for subsequent oxidation

In the light of the foregoing, it is not unreasonable to inquire whether milk fat, too, represents a specially prepared sort of fat, uniquely valuable as a ready source of energy, or whether it corresponds more closely with the less differentiated fats which find their way temporarily into the connective tissue fat depots of the organism If milk fat is formed entirely de novo in the mammary gland, it may be expected to be specific in character and constant in composition independently of the food factor, but even if the milk fat represents in whole or in part the dietary fats, it is quite conceivable that the latter may have been "worked over" in the liver or some other glandular structure so as to become specifically like the fat characteristic of milk The final alternative is that the milk fat is essentially a mixture of imported contributions varying largely with the fat of the diet Breed characteristics, such as the indisputable differences between Holstein and Jersey or Guernsey milk, might, in this event, merely affect the quantity rather than the quality of the fat secreted in milk

[1] The Lipoids ("Fats") of Human Blood editorial The Journal A M A Sept 23 1916 p 956, Blood Lipoids and Diabetes Nov 25 1916 p 1602

In attempting a reinvestigation of the old question as to the extent to which fat present in the food of the cow imparts certain of its own properties to the milk fat, the officers of the Georgia Experiment Station have reverted to the feeding of cottonseed oil, a fat mixture of distinctive character[2] They have found that when cows were fed cottonseed oil, the properties of the butter fat differed from those of a butter fat produced when the animals were not receiving the cottonseed oil The change was greater with the feeding of a large amount of oil It did not occur with maximum intensity immediately, but showed a gradual increase until the seventh day of continued feeding Certain constituents of cottonseed oil could be detected in the butter fat within from twelve to thirty-six hours after feeding the oil

Such were the experimental facts It must not be assumed, however, that a simple transfer of cottonseed oil to the milk fat had occurred In general, the change in properties on feeding oil were the same as those observed on an advance of several weeks in the period of lactation Cottonseed oil, when fed in small quantities, was not transferred in any considerable amounts directly to the milk fat Some of the substances of which the oil is composed apparently were transferred in a greater amount than others The constituents of the oil did not reach the milk fat in the same combinations or proportions in which they exist in cottonseed oil The Georgia investigators accordingly suggest that cottonseed oil and other oils are not transferred, in any considerable quantity, unchanged in composition to the milk fat, but either undergo a kind of "selective absorption" by the animal body, or certain of its constituents are considerably changed before reaching the cells of the milk gland

The evaluation of the Georgia data will doubtless vary with the minds of different readers There are not a few who might look on them as evidence of a marked qualitative variability of milk, and consequently look on the character of the fat supply to a lactating female as a matter of supreme importance Von Furth[3] has presented this point of view by the remark that often the trouble met in changing wet-nurses may in the last count be connected with the biochemistry of fat He adds that there is justice in the demand that in the first place the milk of nursing women be kept constant by selection of an appropriate fat mixture, and again that by proper feeding of cows a milk be produced with fat similar to the fat of human milk We are more inclined, however, to see in the Georgia and other experiments an indication of a vigorous tendency on the part of the body as a whole and the mammary gland in particular to prepare a fat product of fairly uniform character The small variations incident to enormous alterations in the diet tend, in our belief, to substantiate the probability of the essential though not absolute independence of the quality of milk fat from its food precursors Sometimes, in large excursions from the usual dietary conditions, the transforming biochemical mechanisms, if they may so be designated, may be almost overwhelmed by the task of modifying food fat sources for mammary output Small quantities of unusual adventitious products may escape, but this does not appear to represent the usual or seriously significant occurrence Furthermore, it remains to be demonstrated that milk fat containing incidental traces of less common fat residues is in any way detrimental to health The natural yellow color of butter fat is varied by dietary factors without at present exciting any suspicions of undesirability

TEMPERANCE DRINKS AND THE SODA FOUNTAIN

Millions of dollars, representing the return to the government as revenue from the manufacture and sale of alcoholic beverages, attest the enormous consumption of the latter in this country each year Whether it is attributable to the wave of prohibition which is slowly sweeping over this country, or to the development of new tastes side by side with the long standing demand for spirituous liquors, or to both factors combined, in any event a rapidly developing trade in so-called temperance beverages has manifested itself for some time In part this has represented an augmented consumption of drinks like ginger ale and root beer, which have long enjoyed a limited popularity in the United States In larger measure the new trade involves a growing sale of products scarcely used at all in a commercial way a decade or two ago Thus, referring to the grape juice industry, a recent writer[1] reports some astonishing figures for the stimulation of trade in this beverage The production of American unfermented grape juice in the year 1914 amounted to nearly five million gallons in the Chautauqua belt alone

The consumption of what is commonly termed soda water in this country must be much larger The United States has been called the greatest soda fountain country in the world In fact, soda water of the sort dispensed flavored with fruit syrups as a fountain beverage is distinctly an American drink which has found popularity in few other countries, with the possible exception of Australia, where the soda water business is said to be conducted much as it is here The habit of drinking soda water at a "stand" of some sort in summer has gradually stimulated a demand for "hot drinks" at the same establishments in winter, so that hot coffee, chocolate, malted milk, bouillon, etc, have likewise come into vogue for sale to those who drink cold nonalcoholic beverages in summer

[2] Smith F H Wells C A and Ewing P V The Changes in Composition of Butter Fat Produced by Feeding Cottonseed Oil Bull 122 Georgia Expt Sta June, 1916

[3] Von Fürth O *Chemistry of Metabolism translated by A J* Smith, Philadelphia 1916 p 425

[1] *Mendel L B* Changes in the Food Supply and Their Relation to Nutrition, Yale University Press, New Haven 1916 p 41

It is not easy to estimate the magnitude of the current enterprise in this field The retail value of the sodas, "sundaes" and other fountain beverages or refreshments for 1916 has been placed at $500,000,000 For ice cream it was estimated by a statistician of the National Association of Ice Cream Manufacturers that 200,000,000 gallons would be consumed in this country in 1916 At 40 cents a gallon, which is about the minimum price at which ice cream is sold, the American public would be expending no less than $80,000,000 for this delicacy

During all the years in which the liquor saloon has been in existence, scarcely any attempt has been made to regulate its practices in the interest of public or personal hygiene On the other hand, public sanitary regulation of the operation of the soda fountain business has already been introduced within the few years in which the new trade has begun to thrive so prominently In some places the regulations have become more stringent than the restrictions on restaurants, or saloons in which eating and drinking utensils are used For example, in one region the health authorities have decreed that all glasses, cups, spoons, etc, used at fountains must be sterilized after each service Another state has ordered the use of individual paper cups unless all glasses are sterilized Similar legislation having in view the prevention of the spread of communicable disease through the use of unclean glasses has been adopted by local health boards or sanitary authorities in various places Furthermore, provision has been made here and there for medical examination of employees so that the beverages shall not be dispensed by persons liable to spread disease in their occupation How difficult it would be either to secure or to put into practice comparable sanitary regulations in the liquor saloon, where under the existing conditions of the traffic the hygienic hazards must be decidedly more prominent

DUST AND ITS DANGERS

In the clinic of occupational diseases it is well recognized that dust of various sorts is a menace to the health of a large number of wage earners For 1915 it has been estimated by Frederick L Hoffman that at least 10 per cent of workers labored under conditions more or less detrimental to health and life on account of atmospheric pollution commonly classed as dust[1] This impurity may be of the most diverse sorts There are insoluble inorganic dusts, including metals in a state of fine division, silica, sand, coal, marble and similar powders Potter's asthma, grinder's phthisis, and the siderosis among metal polishers and others engaged in metal working are familiar illustrations of the harm done by this class of dusts, which usually produce irritation through being inhaled Others represent soluble inorganic impurities which are more readily absorbed after being swallowed, and are dangerous because of their inherently poisonous qualities A third class, the organic dusts, comprises such widely varying materials as "sawdust, fur, skins, feathers, broom and straw, grains and flours, jute, flax, hemp, cotton, wool, carpet dust, street sweepings, tobacco-box dust, hides and leather, felts, rags, paper, horsehair, etc Typical of the diseases caused by organic dusts are flax dressers' disease, a kind of pneumonia due to the inhalation of particles of flax, alkaloidal poisoning from African boxwood by workmen engaged in shuttle making, and malignant pustule and a febrile disease among rag sorters "[2]

Most persons contemplating the subject of dust and its hygienic aspects for the first time assume that the dangerous factor lies in the distribution of microorganisms in the atmospheric contamination Dust thus is a convenient term which may include a large variety of atmospheric impurities The dust of the home, the schoolroom, the theater or the street can scarcely be of the same character, even if in attenuated amounts, as that which obtains in the distinctively dusty trades Of what does it consist? A recent analysis of the "dust" collected in a vacuum cleaner from the book shelves of the library of an educational institution[3] disclosed, on microscopic examination, hair, green wool, white wool, cotton fibers, fly wings, sand grains, wood, paper, string, celluloid, pieces of finger nails, metallic iron and leather The hair was probably derived from soft hats, the wool and cotton fibers from clothing, sand from the mud tracked in on shoes and the gradual pulverizing of the floor, fly wings from dead flies, and paper from book leaves The remaining articles present explain themselves In a water suspension of this dust, no life could be detected with a lens magnifying 320 diameters

A qualitative examination of the "library dust" showed the presence of the elements iron, aluminum, sodium and calcium, which are easily accounted for by the wear and tear of materials of obvious proximity One of the chief points of interest was the finding of the *Bacillus coli communis* Rees suggests that it may come from several sources, the most probable one being the hands while handling books The bacillus might also be present because of the coughing, sneezing and possible expectoration of people using the library The total number of bacteria in the dust of such a confined space as a library would naturally be high, as the dust would catch the bacteria and have a tendency to hold them

[3] Rees R R, The Analysis of 'Dust' Collected in a Vacuum Cleaner from the Book Shelves of the Rensselaer Polytechnic Institute Library, Science Oct 27 1916, p 618

It might be argued, as Rees does, that where the colon bacillus survives, more harmful bacteria might also remain, such as those producing typhoid fever, cholera, diphtheria and especially tuberculosis, which latter disease is caused by a bacillus especially able to resist the sterilizing influence of drying But the experience of the comparative freedom of paper money, books, and many other articles frequently handled by man, from extensive contamination with harmful micro-organisms gives a feeling of a security from such possible sources of bacterial danger which may or may not be entirely justified Only extensive researches can determine the real limits of safety from the commonest dangers of dust in everyday life

Current Comment

COMPULSORY HEALTH INSURANCE

The United States is practically the only large industrial nation which has not adopted compulsory health insurance A number of states have enacted workmen s compensation laws, which may be regarded as the entering wedge, this will undoubtedly be followed by similar legislation which will provide compensation for medical care during disability from sickness, and include not only the breadwinner but also the dependent members of the family While the medical profession has a very practical interest in the subject, because of the duties and responsibilities assigned to it in the carrying out of these laws, few physicians have recognized its importance The mass of the members of our profession seem not to have awakened to the fact that the interests of the public, as well as their own, require them to become informed on the question and to take an intelligent, active part in framing legislation which is already being considered in a number of states In The Journal, May 6, 1916, it was announced that a committee under the chairmanship of Dr Alexander Lambert, chairman of the Judicial Council, had been appointed to compile information in regard to social insurance and the relation of physicians thereto This committee submitted a report to the House of Delegates[1] at the Detroit session The American Association for Labor Legislation prepared a preliminary draft of a model bill on social insurance in which it has properly left blank the section providing for medical services, while asking the assistance of the medical profession to work out this phase of the problem In this issue is a paper on "Health Insurance and the Medical Profession"[2] by Dr Lambert in which suggestions are made for defining the conditions for medical service under social insurance Like the model bill of the American Association for Labor Legislation, Dr Lambert's paper is not to be regarded as the final word on the question, but as suggesting a basis for discussing the conditions under which medical services may be rendered in the proposed scheme of health insurance The Journal again emphasizes that the time for the medical profession to interest itself in social insurance legislation is now, while legislation is in a formative stage It is hoped that the publication of Dr Lambert's paper will be followed by a constructive discussion of health insurance in the columns of The Journal by its readers

A MEDICAL COMMISSION, BUT NO MEDICAL MAN ON IT

According to the newspapers, President Wilson has nominated as members of the workmen's compensation commission, to administer the federal Employees' Liability Act, the Reverend R McMillan Little of Swarthmore, Pa, a preacher in the United Presbyterian church, a Mrs Axtell of Bellingham, Wash a social worker and a defeated candidate for Congress, and a J J Keegan of Indianapolis, a member of the International Association of Machinists, then a member of the state legislature, and more recently a commissioner of conciliation in the Department of Labor The first of those mentioned above is stated to be a Republican, the second a Progressive, and the third a Democrat, none is a physician Probably 90 per cent of the work of the commission will be medical in character

POISON THE FLY

Although this is not "fly season" in most parts of the United States, the desirability of preparedness may serve as an excuse to refer to antifly measures at this time In *Public Health Reports* it was pertinently remarked

> The practice of swatting despite the faulty biologic reasoning so often urged by its enthusiastic supporters, whereby the effectiveness of a single swat is multiplied many millionfold, certainly does possess the advantage of a definite 100 per cent efficiency Its disadvantage lies chiefly in the effort and earnestness which it demands, factors which are apt to be affected by rising temperature inversely as the multiplication rate among the flies[1]

The problem of destroying the fly larvae in their breeding places, notably in horse manure, is complicated by the fact that many efficient larvicides ultimately produce an injurious effect on the manure so that it cannot be applied in agricultural practice without damage to plant growth This has greatly restricted the promise which borax early gave as a suitable and comparatively inexpensive larvicide The cost of any treatment which must be extensive is also a restrictive item with respect to the application of some otherwise efficient agents Products like cyanids, Paris green and other arsenicals are potent but too toxic for general use on a large scale The newest recommendation of the Department of Agriculture is powdered hellebore, an effective larvicide without action on plant growth[2] For killing flies which have escaped destruction in the larval stage, the Hygienic Laboratory of the Public Health Service has found an eminently satisfactory new agent in salicylic acid In 1 per cent solution it destroys flies which consume it Salicylic acid, unlike the more potent 1 per cent solution of formaldehyd, is not an objectionable substance to handle, and there is little danger of toxic effects from accidental consumption of considerable doses of it With such powerful chemical guns ready to be trained on both the larvae and the adult flies, the antifly campaign of the coming season ought to be memorable for the beneficent effects of its potent instruments of destruction

CHEAP ALUM FOR WATER PURIFICATION

Any development of the process of water purification that diminishes cost is worthy of consideration from the public health standpoint Such an improvement appears to be the new method of making alum recently devised by a well known water purification chemist in this country The process is already in use in four water-filter plants in the United States and one in Canada The chemical improvement is described in a recent number of *Engineering News*,[3] and the notable advantages it presents are there set forth in detail Not only is the alum produced at a low cost, but also it is more effective as a coagulant The advantages are thus summed up

> Alum is made regularly at the several works, by means of simple and low-cost installations It is made up daily—"as you wait," almost—by the ordinary force and under the direction of the chemist or other head of the purification works The resulting product is not only much cheaper than commercial alum but is also far better suited to use as a coagulant—one reason why it is cheaper

Proposed Investigation of Habit-Forming Drugs—In a twenty-page pamphlet for the information of Congress, for consideration in connection with pending amendments to the Harrison Narcotic Law, Charles B Towns, New York, urges that Congress empower the president to appoint a committee, with adequate authority and money, to conduct hearings and make investigations on the drug problem The findings of such a committee, it is said, would enable the states to enact properly correlated legislation According to Mr Towns not more than 10 per cent of those addicted to drug habits are excusable because of physical disabilities Pointing out defects in the Harrison Narcotic Law, Mr Towns claims that any person may have as many physicians as he chooses prescribing for him at the same time, and says "The doctor does not have to find out whether or not the patient is a confirmed drug taker, he can take the man's word for it and prescribe just what the patient asks for" He suggests that the manufacturing, selling, prescribing and administering of opiates be strictly limited to crude opium, laudanum and paregoric (he does not mention apomorphin), which would not inconvenience the medical profession, and would eliminate every unfavorable hazard incident to the use of habit-forming drugs The physician is to be held to an accounting for such opium, laudanum and paregoric as he personally prescribes or administers The regulation of the sale of hypodermic syringes is recommended The nurse is not to be allowed possession of a hypodermic needle except on a physician's order, and then the dose administered is to be at all times strictly regulated by the physician

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest, such as relate to society activities, new hospitals, education, public health, etc)

ALABAMA

New State Health Officer—Dr William H Sanders, Montgomery, who has served the state for nearly twenty-one years as state health officer, retired, January 9, on account of ill health Dr Samuel W Welch, Talladega, has been appointed health officer——Dr William W Dinsmore, Montgomery, will become state prison inspector, about April 17, succeeding Dr William H Oates, Montgomery

CALIFORNIA

New Buildings at County Hospital—Bids have been received by the Los Angeles County Board of Supervisors for the construction at the County Hospital of seven additional units five tuberculosis wards, each averaging 44 by 150 feet, a dining hall and a maternity building

Proposes Merger of Health Board—A bill is to be introduced in the legislature by Senator Edgar A Luce, San Diego, which provides for the merger of the state boards of health, medical examiners, dental examiners, optometry and embalmers in a single board to consist of three members

State Examiners' Board Elects Officers—At the annual meeting of the State Board of Medical Examiners, held in Sacramento, January 9, Dr Arthur M Smith, Oakland, was elected president, Dr Percy T Phillips, Santa Cruz, vice president, and Dr Charles B Pinkham, San Francisco, secretary-treasurer (reelected) At this meeting the board is said to have revoked the license of Dr Calvin L Case, Oakland, charged with having prescribed morphin for a drug addict not under his continuous care

Memorial Hospital—Plans have been prepared for the new John P Scripps Memorial Hospital for working men and women in San Diego As a preliminary step, the San Diego Diagnostic Group Clinic for John P Scripps Foundation is at once to be put into operation in the Scripps residence which has been donated for that purpose Mr Scripps guarantees a sum up to $250,000 for the clinic and the erection, furnishing and equipment of the hospital He also agrees for a term of years to meet, up to the sum of $30,000, any deficit in the amount required for the maintenance of the institution Drs Bernard J O Neill, Harry C Loos, John E Jennison, Vernon G Clark and Harold A Thompson comprise the executive committee of the institution

CONNECTICUT

Personal—Dr Edward J Murray, Meriden, has been appointed superintendent of the Southwestern Minnesota Tuberculosis Sanatorium, Worthington, Minn

Hartford Physicians Elect—At the seventieth annual meeting of the Hartford Medical Society, January 2, Dr Charles C Beach was elected president, Dr Charles E Taft, vice president, Dr Amos T Harrington, secretary, and Dr Philip D Bunce treasurer The Hartford Medical Society Cup was awarded to Dr Everett J McKnight

ILLINOIS

Personal—Dr Charles B Johnson, Champaign, has been appointed a director of the Champaign County Tuberculosis Sanatorium, which was authorized at the November election ——At the annual meeting of the staff of St Francis' Hospital, Kewanee, January 11, Dr Peter J McDermott was elected president, Dr Gideon H Hoffman vice president, and Dr H Nelson Heflin, secretary, all of Kewanee——Dr William L Hanson, Belleville, is on his way to England, where he will enter the Military Hospital Service——Prof Julius O Stieglitz has been elected president of the American Chemical Society for 1917

Chicago

Smallpox—Two cases of smallpox were found, January 14, one in St Luke's Hospital, and the other in Cook County Hospital Both patients were taken to the new Isolation Hospital

New Superintendent of Hospital—Sister Mary Rita of the Order of Mercy has assumed the duties of superintendent of the Mercy Hospital, succeeding Sister Mary Raphael McGill, deceased

Convalescent Home for Wesley Hospital—Mrs Sarah Wheeler has donated her home and property in Lake Bluff, valued at $50,000, to the Wesley Memorial Hospital The property will be known as the Wheeler Convalescent Home

New Officers—Chicago Society of Internal Medicine, January 22 president, Dr Robert B Preble, vice president, Dr Rollin T Woodyatt, and secretary-treasurer, Dr Charles A Elliott (reelected) ——Chicago Ophthalmological Society, January 15 president, Dr Paul Guilford, vice president, Dr Francis Lane, and secretary-treasurer, Dr Major H Worthington

Laboratory Building for County Hospital—A subcommittee of the executive committee of the Cook County Hospital staff recently prepared a memorandum which was submitted to Mr Peter Reinberg, president of the Cook County Commissioners, concerning the provision of a laboratory building for the Cook County Hospital The committee consisted of Dr Edwin R LeCount, chairman, and Drs J Rawson Pennington, Maximilian Herzog, David J Davis and Robert F Zeit The committee notes that there is great need of a new building for laboratory service on the Cook County Hospital ground and that the temporary quarters now occupied are crowded and wholly inadequate An investigation was made several years ago concerning the need of the institution for a laboratory building, and this need is now much greater The original report of the committee appeared in the transactions of the county board, and it is proposed to elaborate the report and bring it up to date if the commissioners decide to take action in the matter

Personal—Dr William Healy who has been head of the Chicago Juvenile Psychopathic Institute for the last seven years, has resigned to accept the position of director of the Harvey H Baker Foundation, Boston This foundation was established in memory of the late Judge Baker of the Juvenile Court, to aid that court by making psychopathic examinations of infant children Dr Healy will be given a complimentary dinner January 30 by the Chicago Ethical Society at the City Club ——Dr George G Davis lieutenant colonel of the Royal Army Reserve Medical Corps spoke before the Chicago Alumni Club January 20, on his experiences in a British base hospital in France ——Dr Roscoe C Giles heads the list of eligibles for appointments on the staff of the Municipal Tuberculosis Sanatorium ——Dr Arthur Schuettler was operated on for appendicitis in the Ravenswood Hospital, January 18 ——Dr Arthur C Beverlein, Colon, Panama, is visiting his parents in Chicago ——Dr William D Napheys has been appointed a member of the staff of the Government Hospital for the Insane Washington, D C ——Dr Allen B Kanavel delivered three addresses on cancer in Lincoln, Neb, January 6 speaking before the Women's Club the physicians of the city and the public

KANSAS

Personal—Dr Bert L Stinson, Great Bend, has been elected health officer of Great Bend and physician of Barton County ——Dr Charles M Siever, Holton, has been elected physician to the Kansas State Agricultural College, Manhattan

Asks Large Appropriation for Sanatorium—Dr Chauncey S Kenney, superintendent of the State Tuberculosis Sanatorium, Norton has asked an appropriation of $180,000 for new buildings and improvements, and one of $120,000 for maintenance and salaries for the next two years Dr Kenney claims that these appropriations will permit the construction of six new pavilions accommodating twenty patients each an administration building, water works and fire protection, and enough help to farm the 240 acres of land at the institution

MAINE

Licenses Revoked—An official communication states that at the meeting of Maine Board of Registration of Medicine, held Nov 14 and 15, 1916 the licenses of Clarence J Prickett and Reuben Calhoun Clinkscales were revoked on account of fraud in connection with the obtaining of their licenses, both having claimed to have graduated from the extinct Southern College of Medicine and Surgery of Atlanta, Ga

New Officers—York County Medical Society, eighty-seventh quarterly meeting, at Biddeford president, Dr Charles E Cook, South Berwick, vice president, Dr Clarence F Kendall, Biddeford and secretary, Dr A Leon Jones, Old Orchard ——Kennebec County Medical Society, at Augusta, December 7 president, Dr Oscar C S Davies, Augusta, vice president, Dr Arthur U Desjardins, Waterville, and secretary, Dr Sylvester J Beach, Augusta

MARYLAND

Hospital and Ambulance Companies Mustered Out—Field Hospital Company No 1 and Ambulance Company No 1, commanded by Major J Harry Ullrich, M C, Md N G, which have been on duty at Eagle Pass for six months, were mustered out of the United States service, January 6

Meetings—At the annual meeting of the Baltimore County Medical Society, held January 17, officers were elected as follows president, Dr Martin F Sloan, Towson, vice president, Dr J Percy Wade, Catonsville and secretary-treasurer Dr Frank W Keating, Owings Mills It was decided to devote the next meeting to mental diseases of children and to invite the Baltimore and the Howard County Medical associations to meet with them

Personal—Senior Surg Henry R Carter, U S P H S Baltimore, superintendent of the Marine Hospital, is at Columbia, S C, where he will superintend sanitary work on the new filtration plant in that city In his absence Dr Charles Vogel, Baltimore will have charge of the hospital ——Dr William E Martin, Harrisonville, narrowly escaped being killed recently when his automobile skidded on the ice and rolled over an embankment He escaped with body bruises ——Drs Herbert Schoenrich and G Milton Linthicum, Baltimore, who have been serving with the Fifth Infantry have resigned ——Dr Archibald C Harrison, Baltimore, was *operated on recently for appendicitis at St Joseph's Hospital* ——Dr John F Hogan has been placed in charge of the recently organized Bureau of Communicable Diseases, Baltimore Under this bureau are included health wardens, nursing, the tuberculosis dispensary, school physicians, vital statistics fumigation, complaints, tenement houses and the Sydenham Hospital ——Dr Stacy T Noland, Cambridge, assistant physician at the Eastern Shore State Hospital, has resigned to accept a similar position at the Montana State Hospital for insane ——Dr Richard E Yellott, Fallston is reported to be seriously ill at the Hebrew Hospital, Baltimore

MASSACHUSETTS

New College of Pharmacy Building—Through the generosity of George Robert White, Boston, the Massachusetts College of Pharmacy is to have a new building located on Longwood Avenue, Roxbury

New Bills Regarding Tuberculosis—The Massachusetts Association of Boards of Health has submitted two bills to the Massachusetts legislature The first is an act relative to the removal of certain persons affected with tuberculosis, and the second an act to provide for the care and treatment of wilfully careless and incorrigible tuberculosis patients

Asks Time to Study Insurance Problem—Dr Samuel D Woodward, president of the Massachusetts Medical Society has presented a petition asking the special recess committee on social insurance of the state legislature not to recommend any legislation on health insurance until the medical profession and the public have had more time to study the question

Health Boards Meet—The annual meeting of the Massachusetts Association of Boards of Health was held at the Brunswick Hotel Boston, January 25 Dr Donald B Armstrong, Framingham, presented a paper on "The Community Health and Tuberculosis Demonstration in Framingham," and Dr Thomas F Harrington, Boston, medical deputy commissioner of the state board of labor and industries, delivered an address on "Industrial Health"

Personal—Dr Orran G Gilley, physician at the Charles Street Jail, Boston, for nearly five years, has resigned and has been succeeded by Dr Harry H Colburn ——Dr Thomas B McQuaid has been appointed city physician of Everett succeeding Dr Ralph W McAllester ——Dr Richard H Morris has been appointed a member of the board of health of Everett ——Dr Scott W Mooring has been elected a member of the board of health of Gloucester, succeeding Dr Charles H Morrow, retired after ten years' service ——Dr Howard A Streeter, Marblehead has been appointed district health officer in Berkshire District, succeeding Dr Stanley H Osborn, North Adams ——Dr William J Brickley for six years resident surgeon at the Haymarket Square Relief Hospital, Boston, has resigned to enter private practice ——Dr Henry S Rowen Brighton, has been appointed a trustee of the Boston City Hospital, succeeding the late Dr Francis J Keany

MICHIGAN

Effect of General Vaccination—The general vaccination order issued by the health commissioner of Escanaba a year ago resulted in entire freedom of the city from smallpox during 1916 Surrounding towns are said to have had many cases

State Board Asks Funds—The state board of health, in its annual report, asks for an increased appropriation owing to the expense of the new laboratory in the Upper Peninsula It recommends that the state be divided into districts, and that the counties should organize as units for tuberculosis work A special appropriation for tuberculosis is asked for, and the need for two state sanatoriums for the treatment of tuberculosis is emphasized

MINNESOTA

Hospital Opened—The Lake City Hospital was opened New Year's Day

Personal—At the annual meeting of the state board of health, Dr William A Jones, Minneapolis, was reelected president, Dr Christopher Graham, Rochester, vice president and the executive committee was also reappointed without change——Dr Harry M Guilford has been appointed commissioner of health of Minneapolis

New Sanatorium Opened—The sanatorium of the Southwestern Minnesota Tuberculosis Association, near Worthington, opened, January 14, cost $100,000 one half provided by the state and the other half by the counties of Rock, Pipestone, Lincoln Lyon, Murray, Nobles Jackson and Cottonwood The institution accommodates fifty patients

NEW YORK

Health Department Banquet—The tenth annual banquet of the health department of Buffalo was held, January 17 at the Hotel Statler The principal address was delivered by Dr William A. Evans, Chicago, on 'Health Insurance" Dr William G Bissell, Buffalo, was chairman of the committee of arrangements

Personal—Dr S Meredith Strong Flushing has been appointed president of the staff of the Flushing Hospital, succeeding Dr Charles B Story, Bayside——Dr Anthony F de Graffenried Bayside, has been elected secretary of the staff of the hospital, succeeding Dr George J. Lawrence, Flushing, who is on duty on the southern frontier——Dr James E. Mansfield has succeeded Dr Maurice J McGrath as local surgeon of the New York Central Lines, at Oswego ——Dr Barton D Skinner, Greenport, was struck on the head by a falling limb of a tree, January 4, and rendered unconscious

New York City

New Officers—Bronx County Medical Society, December 20 president, Dr J Lewis Amster, vice presidents, Drs John J Decker and Maximilian Ziegler, secretary, Dr Isidore J Lansman, and treasurer, Dr Philip A Eichler

Harvey Society Lecture—The next lecture of the present course will be given at the New York Academy of Medicine on the evening of February 3 by Prof James W Jobling, Vanderbilt University His subject will be 'The Influence of Nonspecific Substances on Infections"

Personal—Dr William S Stone has been appointed assistant director of cancer research in the Memorial Hospital ——Dr Simon Flexner has been elected foreign associate member of the Paris Academy of Medicine——Dr Henry Kendall has been appointed assistant visiting physician to the Sydenham Hospital

Annual Report of Academy—The report of the president of the New York Academy of Medicine shows that in the last twenty-five years the activities of the academy have increased five-fold, and that at present the library, reading room and journal room are greatly overtaxed Two solutions of this difficulty are discussed One is the sale of the present property and the erection of a new plant elsewhere, the other is the erection of an addition to the present building on the adjacent 25-foot lot running through from Forty-Third to Forty-Fourth Street and already in possession of the academy The second plan seems most practical and would probably provide abundant facilities for the next twenty years——The council reports the successful formation of a new section on historical medicine. The trustees report that during the past year the endowment fund has been increased by $1,600 and the general permanent fund by $100——The academy extension fund has received paid subscriptions amounting to $112,328——The committee on library reports the receipt of $100 from the First District Dental Society for the purchase of books and journals on dentistry——From Dec. 9, 1915, to Dec 10, 1916, there were added to the library 3,911 volumes and 3,372 pamphlets

NORTH DAKOTA

New Hospital for Minot—Articles of incorporation have been filed with the secretary of state by the Minot General Hospital Company with a capital stock of $200,000——John Maloney, Minot, has offered to donate 4 acres of land for a site on which to erect this hospital He also agrees to excavate the basement and to provide pure drinking water for the institution

Appropriation Asked for Health Laboratory—For the protection of the health of the people and to aid in the reduction of the death rate, the state public health laboratory has asked an appropriation of $12,000 from the legislature The main laboratory is situated at the University of North Dakota, Grand Forks, and there are three branches, one each at Fargo, Minot and Bismarck——The new quarters of the branch of the public health laboratory at Minot are in the Anderson Building, and the laboratory is in charge of Dr Albert M Larson

PENNSYLVANIA

New Officers—At the annual meeting and banquet of the Allegheny County Medical Society, held at Pittsburgh, January 9, the chief address was given by Dr William S O Neill Sherman of the United States Steel Corporation on the treatment of wounds in war Dr John M Thorne was elected president, Dr Ellis S Montgomery, vice president, Dr Carey J Vaux, secretary, and Dr William C Bryant, treasurer

Personal—Dr Jacob T Butz, for twelve years secretary of the Lehigh County Medical Society, was presented with a black alligator skin traveling bag and a traveling toilet set by the society——Dr Walter Lathrop has been reelected surgeon in chief and superintendent of the Hazelton State Hospital for the twentieth consecutive term——Dr. Charles E Hannon has been elected president of the staff of Mercy Hospital, Johnstown——Dr Lawrence A Sheridan, Wilkes-Barre has been elected president of the medical and surgical staff of Mercy Hospital——Dr Wilson H Rothermel Reading, who has been ill and confined to his house for seven weeks, has resumed his professional duties——Dr Harry J Kirby, Ellsworth, is reported to be critically ill in a Harrisburg hospital, the result of an automobile accident——Dr Eugene B Campbell, Williamsport is reported to be seriously ill——Dr Samuel S Shields, Carbondale, fell on an icy sidewalk, January 6, fracturing his left arm at the wrist

Philadelphia

Medical Club Election—The Medical Club of Philadelphia held its annual meeting, January 19, and elected Dr Charles K. Mills, president, Drs Gassaway O Ring and William Martin, vice presidents, Dr William S Wray, secretary, and Dr Lewis H Adler, treasurer

Symposium on Military Surgery—The program of the College of Physicians of Philadelphia for January 22 was devoted to "Military Surgery, Based on Experiences in the American Ambulance' Dr Fred T Murphy, St Louis, read a paper on "The Result of Operations on Bones", Dr Robert D Osgood, Boston, discussed the "Orthopedic Phases of Military Surgery", Dr Charles F Mitchell read a paper on 'Compound Fractures," and Dr Richard H Harte one on "Plastic Operations"

Personal—Dr William W Keen was the guest of honor at a dinner given by the faculty of Brown University at the University Club, Providence, R I, January 16——Dr W Wayne Babcock, chief of the surgical staff of the Samaritan Hospital, who underwent an operation for appendicitis, December 15, returned home convalescent, January 6——Dr R Tait McKenzie, who recently returned from England, delivered an address before the Los Angeles County Medical Society, December 29

TEXAS

Health Campaign in Polk County—To demonstrate the feasibility of preventing uncinariasis, typhoid fever, paratyphoid, malaria and pellagra, a four months' campaign has been commenced in east Texas under the direction of Dr Wesley C Becker, field director of the International Health Board of the Rockefeller Foundation. This board, with the cooperation of the state board of health, is financing this campaign

Personal—Dr Lee O Foster, Fort Worth, was run over by an automobile, December 23, and severely injured——State Health Officer William B Collins has returned from a tour of the principal ports of Central America and the West Indies——Dr Philip Douglas Spohn, Corpus Christi, has been appointed a surgeon in the hospital service of England and has left for his new post of duty——Dr Samuel E Thompson, medical director of the State Tuberculosis Sanatorium, Carlsbad has resigned——Dr Marcus M Carr, superintendent of the Parkland Hospital, Dallas, has resigned

CANADA

Prevalence of Syphilis—Dr Charles K Clarke, superintendent of the Toronto General Hospital, headed a deputation to Ottawa last week which appeared before the Canadian Conservation Commission and presented startling figures to that commission It stated that more than 12 per cent of the patients admitted to the public wards of the Toronto General Hospital for various diseases, medical and surgical, have syphilis Dr Clarke considers this a greater menace than tuberculosis Dr William Boldie asserted that Dominion control was necessary owing to the immigration laws being made by the Dominion Parliament Others who accompanied the delegation were Prof Benjamin P Watson, Prof John J Mackenzie Dr Charles H Hair, chief of the special treatment clinic at the Toronto General Hospital, and Dr Herbert K Detweiler all of Toronto

Hospital News—The Laval Hospital Unit is being established temporarily in Paris with 1 400 beds Its own building, which is now under construction will be ready in May——The Canadian Pacific Railway Company has agreed to transform six sleeping cars into hospital cars for the Canadian Military Hospitals Commission This will make a total of sixteen cars under the control of the commission These cars will be used between Winnipeg and the Pacific Coast, while the ten government cars will be used between Halifax and Winnipeg——The Canadian Hospitals Commission is advocating the sending of all military medical men in Canadian hospitals overseas filling their places by returned surgeons——A deputation headed by Sir Adam Beck came down to Toronto recently from London Ont to request the Ontario government to establish a hospital in London for returned soldiers It was suggested that a new building be erected on the grounds of the Hospital for Mental Diseases and that later on it could be utilized for hospital purposes for those afflicted with mental disease

Personal—Dr Melville H Embee has returned to Toronto from overseas on leave——Capt Alexander H Taylor medical officer Twenty-Fourth Battalion Victoria Rifles, has been awarded the Military Cross for conspicuous bravery——Dr H R Smith Toronto, medical officer, First King s Own Royal Lancasters was severely wounded in December and when last heard from was in the Rouen Hospital——Dr William A Macdonald Windsor Ont, has moved to Toronto, where he is attached to Exhibition Camp Base Hospital as an officer in the C A M C——Dr F R Nicolle (captain) Chatham Ont, contracted trench fever some months ago He has been in King's Hospital, London, England, since November——Dr Charles Stuart Wynne, sometime house physician at the Toronto General Hospital, his been awarded the Military Cross, 'for working all night dressing and attending the wounded in the open thereby saving many lives'——Capt Leeming A Carr Hamilton, son of Dr Leeming Carr has been awarded the Military Cross for continually leading stretcher bearers under heavy fire and on many occasions himself rescuing wounded men——Col Charles W F Gorrell, Ottawa formerly commanding officer, Taplow Hospital, resigned his position some time ago, and when last heard from was ill in a private hospital in London England——As a result of representations made to the British Embassy at Washington, Hon Dr Henri S Beland, formerly postmaster general of Canada, who was made a prisoner of war in Belgium early in the campaign will soon be liberated——Col Herbert A Bruce is not returning to Toronto at the present time He has accepted from the Royal Army Medical Service the appointment of surgeon in chief to twelve large British hospitals in France, and will likely remain at this post until the end of the war——Major John A Amyot, Toronto, formerly director of the Ontario Board of Health laboratories and professor of hygiene and public medicine in the University of Toronto, has been appointed sanitary adviser in England to the Canadian forces

GENERAL

Grayson Now Rear Admiral—January 18, President Wilson nominated as one of the five new rear admirals of the navy, two of whom are taken from the Medical Corps, Passed Asst Surg Cary T Grayson, naval aid and personal physician to the president This promotion advances Dr Grayson 114 numbers Dr Grayson, who was born Oct 11, 1878, in Virginia, was graduated from the University of the South Sewanee, Tenn, in 1903, and entered the navy June 28, 1904, as assistant surgeon He was promoted to passed assistant surgeon three years later, and had had up to the beginning of 1916 a little more than five years' sea service and more than six years' shore or other duty He was first assigned to duty at the White House during the administration of President Taft and was continued in that position by President Wilson when he assumed the presidency

American Academy of Public Health—At a meeting held in Cincinnati October 23, by twenty-nine physicians interested in public health matters, it was decided to establish an organization to be known as the American Academy of Public Health Qualifications for membership are to be based on achievements in public health work and scholarship in public health science The meetings of the organization will be devoted to the submitting of reports on public health problems and general discussion by the members According to the constitution adopted, the membership for the first year is limited to fifty and five new members may be added each year The following officers were elected pro tem president Carl L Alsberg, Washington, D C, vice president Prof H W Conn and secretary, Dr Charles E North 30 Church Street, New York

Bequests and Donations—The following bequests and donations have recently been announced

Servants for the Relief of Incurable Cancer New York $5 000 and St Mary s Hospital for Crippled Children $2 000 by the will of Mrs Eliza Haynes

St Vincent's Hospital New York $260 000 for a cancer hospital to be operated as a branch of the institution

Germantown (Philadelphia) Hospital a donation of $110 000 as a memorial for her daughters Mrs Charles W Harkness New York and Mrs Anna W Darnell by Mrs William C Warder Germantown

Dr Clarence P Foss Brunswick Me the entire estate of Mrs Susan York Brunswick valued at $20 000

Montefiore Home and Hospital, New York a donation of $100 000 by Jacob H Schiff

Hahnemann Hospital New York $72 494 by the will of Juliet C Percival

Mercy Hospital Chicago Mercy Orphan Asylum and St Charles Illinois, School Board the estate of Robert J Haynes valued at more than half a million dollars subject to the upholding by the court of the decision of Master in Chancery Hamlin

Massachusetts Homeopathic Hospital Boston $25 000 as a trust fund to be known as the Kate A Morrell Fund by the will of George Morrell

Universal Military Training—On December 27 letters were mailed to the presidents and to certain past presidents of the American Medical Association and of other national medical organizations of a special character and to the same officers of state societies inviting them to occupy the time at the hearing before the Senate Committee on Military Affairs which had been assigned to Dr Lucien Howe Buffalo, or to join in a letter to the chairman of the committee approving of universal military training Out of a total of 117 replies received previous to the hearing, 112, including presidents or past presidents of thirty-two state associations, gave their unqualified approval as indicated in the letter, four were doubtful or hesitated to commit themselves and one was opposed to the military aspects of the bill Several letters came too late to be presented At the hearing, Dr Howe made clear the positions of those who signed the letter to the committee, read abstracts from a number of the letters and presented them to the committee In presenting these letters, stress was laid on the fact that each signer expressed only his individual opinion, and not that of any organization with which he was then or had been associated The bill was advocated because of two provisions which would tend to improve the health of boys or young men These were first, a uniform and thorough examination of boys or young men such as would reveal any physical imperfections, and therefore lead to the adoption of means for their correction, and second, the gymnastic exercises and military training would tend to improvement of the general health Dr Hugh H Young, Baltimore, then presented to the committee other physicians who joined in the plea for universal training—beginning with simple exercises at home for boys of about 12, or if that plan were deemed impracticable by the committee, they advocated intensive military training for young men of about 18

FOREIGN

Extra Sugar for Infants in Berlin—A card is now issued in Berlin entitling infants under 1 year old to an extra half pound of sugar per month

Exchange of Medical Prisoners of War—The *Munchener medizinische Wochenschrift* states that Germany and Russia have come to an agreement respecting the exchange of physicians who have been taken prisoners in the war One physician is to be retained for each 2,500 war prisoners, and all the rest are to be allowed to return to their homes

Universal Patriotic Service—The German Reichstag recently passed a bill imposing universal patriotic service on every male German between the ages of 7 and 60 According to the new law, if one locality is overabundantly supplied with physicians, while another has too few, some of the physicians can be transferred The *Deutsche medizinische Wochenschrift*, commenting on the bill remarks that it is to be hoped that such measures will be enforced only in cooperation with medical organizations, and will not be carried out arbitrarily Physicians will probably be called on to report on the conditions of health of persons affected by the law Medical students can be called to care for the sick and wounded, and the time thus spent will be credited to them as those on active service now are being credited

Child Welfare Work—The Prussian minister of the interior has recently notified the provincial authorities (*Regierungspräsidenten*) to take active measures at once to train the older girls and the mothers in means to combat infant mortality, and in child welfare work of all kinds Besides courses of lectures on the care of infants and young children, public lectures mother s evenings and similar measures are to be inaugurated He urged that the woman s organizations the Red Cross and other benevolent associations endeavor to increase their efficiency He also suggested that health officers, communal physicians pediatrists and women physicians, teachers, ministers and others help, either personally or by providing lecturers In several communities, courses of lectures are being held for young girls and mothers who meet two or three evenings a week for this purpose and occasionally visit infant asylums and day nurseries for practical demonstrations The minister of the interior also urged distribution of pamphlets and circulars on the care of young children

Deaths in the Profession Abroad—The first woman physician in Switzerland in modern times and hence the first in Europe has recently died at Zurich Dr Marie Heim-Vogtlin aged 71 She had been practicing in Zurich since 1874 and had written a number of popular scientific works, especially on the care of infants——Bruns, professor of neurology at the University of Hannover and chief of the hospital for children's diseases, aged 58——P Herzberg of Berlin, aged 70 the pioneer in Germany for the movement in favor of cremation, long president of the Verein für Feuerbestattung ——J Benario long a co-worker with Ehrlich, aged 48—— E Hagenbach-Burckhardt, professor of diseases of children at the University of Basel, aged 76——Achille De Giovanni senator of the realm and director of the general medical clinic of the University of Padua Italy, aged 78 He was well known as a pathologist clinician biologist and philosopher, and had published works in these various lines especially on the relations between the morphology of the human body and the predisposition to disease .In the last few years he had taken a leading part in the attempt to control the spread of tuberculosis——E Gaupp, professor of anatomy at the University of Breslau, aged 56

Prophylaxis of Venereal Diseases in Prussia—The *Allgemeine medizinische Central-Zeitung* states that the various health insurance organizations of Prussia have established seventy free consulting dispensaries for sexual diseases A conference was held recently at the Berlin Central Office for Social Insurance which was attended by representatives of the various insurance organizations and of the larger medical associations Realizing that defective or unsuitable treatment of venereal diseases is a danger not only to the diseased themselves but also a menace to the general welfare, the conference unanimously voted in favor of continuing after the war, the measures enforced during the war, by the orders of the military commanders, against quackery in the treatment of venereal disease. The conference declared that these diseases can be successfully controlled only when quackery is legally excluded It should be illegal for any person, not a registered physician to treat sexual diseases in any way, regardless of the site of the disease Laws should also be passed prohibiting the dispensing of remedies against sexual diseases by drug stores and other establishments without a physician's prescription, and prohibiting the distribution of circulars and pamphlets which encourage self-treatment of sexual diseases even in veiled terms as testimonials, expressions of gratitude recommendations and advice All distant treatment of sexual diseases as well as every public offer to treat patients of this class should be absolutely prohibited

WAR NOTES

Contributions to British Red Cross—The *Times* Red Cross Fund which is being supported also by other newspapers passed the $30 000,000 mark, January 17

Italian Field Hospital Shelled—An official communication from Rome January 12 states that Austrian batteries shelled one of the field hospitals at Andrami in the Upper Cordevole, although it was visibly marked with a Red Cross

Relief Party Reaches Saloniki—A telegram from Saloniki January 11, states that twenty-eight Americans comprising Section Ten of the American Field Ambulance in France have arrived at Saloniki on their way to the French front in Macedonia to relieve another section which has been in service since October

The American Red Cross and European War Relief—The American Red Cross has issued a statement to the public showing what it has accomplished in European War Relief From Aug 6, 1914, to Sept 30, 1916, there were received contributions of $2 144,968 17 of which $2,007,584 62 was disbursed Of the money received $412 635 04 was designated and used for certain specific purposes Supplies valued at $978 309 54 were also donated during this period During the first months of the war the Military Relief Work of the Red Cross involved the sending of sixteen hospital units to the seven countries engaged in war at an expense of $352,000 It also joined with the Rockefeller Foundation to send a sanitary expedition to Serbia, which was then suffering from typhus fever The cost of this expedition was about $180 000 For Serbian relief a quantity of food supplies was shipped across the Roumanian border by way of Hungary to Belgrade In this way 318 carloads of food supplies were shipped up to the end of August Food supplies were sent into Serbia from the United States and Switzerland the approximate cost of this relief being $120,000 Red Cross representatives are now

in Greece, ready with emergency relief funds and supplies for use in Serbia In conjunction with the Armenian and Syrian Relief Committee a cargo of food, clothing and medical supplies is on its way to Beirut, where it will be distributed jointly by local Red Cross chapters and the Turkish Red Crescent For many months a Red Cross Committee has provided relief for 5,000 refugees brought from Armenia to Egypt Working through Vladivostok, Tientsin and Peking, the American Red Cross has done much to help the thousands of prisoners of war and interned civilians in the interior of Siberia On the preceding page is a summary of the work of the American Red Cross from the outbreak of hostilities until Sept 30, 1916

LONDON LETTER

LONDON, Jan 1, 1917

The State and the Treatment of Venereal Diseases

A memorandum has just been issued by the Local Government Board to county and borough councils setting out the returns required to be made by the authorities of institutions approved by the board under the regulations for the diagnosis or treatment of venereal diseases The board has also prescribed a form of register to be kept by the pathologists of approved laboratories, and it has prepared for the consideration of hospitals and other institutions a suggested system of case papers and registers A number of leaflets have been prepared for use certain of them for the information of patients, and suggestions to local authorities for publicly announcing the facilities to be provided for treatment Incidentally, mention is made of the fact that at present the board has approved of kharsivan, arsenobillon and novarsenobillon as substitutes for salvarsan The board recommends that the necessary outfits for the collection of pathologic specimens should be supplied gratuitously to physicians, and it also suggests that a uniform payment of 72 cents per specimen should be made to cover out-of-pocket expenses in the transmission of specimens to laboratories

A large number of prominent women including the leading women physicians continue to advocate in the press compulsory notification of all persons infected with venereal disease, and they point out that compulsory notification exists in Denmark They say that it has never been found possible to protect the community from the ravages of infectious and contagious diseases by educative means alone, compulsion has always been necessary and has proved the best education So far the medical profession has opposed compulsory notification on the ground that it would lead to concealment and treatment by quacks, and the government has accepted this decision

Trinitrotoluene Poisoning

The manufacture of the high explosive trinitrotoluene on a large scale has led to the discovery that it may be dangerous to the workers So far there have been fifty fatal cases—a very small percentage when the number of workers is considered Absorption by the skin appears to be the chief channel by which the vapor becomes poisonous This absorption is shown by the characteristic yellow staining of the face and hair lasting for some weeks, to which munition workers handling the explosive are exposed A further stage in this discoloration is the advent of dermatitis, due to the direct irritant action of the poison Next in order of frequency come digestive troubles in varying degree and more seriously degenerative blood changes Worst of all, there is a direct destructive effect on the liver To the latter change is attributable the toxic jaundice from which the fatalities have ensued In other cases, the extent of the toxemia is manifested by 'the pallor of the face, and the ashen grey color of the lips" The fact has been elicited by the inquiry that some workers are susceptible to the poison and others not The latter are by far the larger class, and these apparently remain immune, even after long exposure to the poison On the other hand, any degree of susceptibility is a source of danger to a worker, for among these jaundice has been found to develop rapidly—within the limits of the fifth and sixteenth weeks of exposure Age, too, seems to be a factor of incidence of the symptoms, as in eight deaths out of eleven, due to jaundice, the sufferers were less than 18 years old In a matter of such national concern it was imperative to devise means for the protection of the workers, and strenuous efforts are being made to check the evil A scheme of preventive measures has been elaborated Only persons of sound health, between the ages of 20 and 50 are employed All the workers once a week are subjected to medical inspection Every fortnight they are removed from the trinitrotoluene zone for employment in other departments Means are resorted to for preventing the formation of trinitrotoluene dust, and for getting rid of fumes Absolute cleanliness of the face and hands before meals and before leaving the factory is insisted on, and plunge and shower baths are provided

The Color Bar at a London Hospital

Probably no civilized country is so free from racial prejudices as England, and it is only on the rarest occasions that a 'color line" is ever in evidence, as is illustrated by a recent advertisement in the *Lancet* of the Paddington Green Children's Hospital for house physician and surgeon The advertisement stated that "as this is a children's hospital, applications from Indian or Egyptian students cannot be entertained" This aroused protests in the columns of the *Lancet* from Indian physicians in this country One pointed out that he is resident medical officer at East London Hospital for Children and that the house physician there is an Indian, too At the same time he held that there is a prejudice against Indians Another sarcastically asked why the children's hospital is put forward as an excuse for excluding Indians Does it mean that Indians are objectionable to children and their mothers? He gives his own experience and that of other Indians which shows that this is not true He adds that the patients have far less prejudice against Indians than the heads of institutions This is no doubt true The London poor are quite without racial prejudices Several Indian physicians practice among them and are most popular Indeed, their race is in one way an advantage as people have the impression that they are possessed of some special skill denied to the ordinary Englishman This may be compared to the prejudice in favor of foreigners which exists in several directions Thus English musicians have found it an advantage to pose as foreigners

The National Institute of Mothercraft

A projected national institute of mothercraft is gradually progressing toward the final realization of an important and far-reaching scheme The committee includes leading pediatricians and medical women A site has not yet been found owing to the difficulty of getting a suitable one in a central position It is important that the institute should be easily accessible from all parts of London It is not intended to be a vast school for mothers, but to be the headquarters of all information and material for the training of students and workers concerned in the welfare of mothers and children On the ground floor will be a day nursery nursery schools for children of from 3 to 4 and 4 to 5 years, a school for mothers, and an infant clinic The first floor will be for administration purposes On the second floor will be the museum and exhibition, the reference and reading library the observation ward for resident babies and the students' training department The third floor will be devoted to laboratory and research work The aim of the originators of the institute is to make it, when it takes definite form, a place where every effective preventive agency shall be put into operation to combat infant, antenatal and maternal mortality All the scattered activities will be collected under one roof and every department will be organized by specialists and linked up in such a way that any provincial authority wishing to adopt, as best suited to its requirements, one branch of infant welfare will find at the institute a practical and complete model to draw on The institute is intended to be a memorial to those who have fallen in the war, and the Duchess of Marlborough is asking for $1,000,000 the provisional estimate of its cost

PARIS LETTER

PARIS, Dec 28 1916

Wounds of the Large Vessels Without Immediate Hemorrhage

This subject continues to command the attention of the Societe de chirurgie de Paris Dr Planson reported two cases of so-called 'dry" wounds of large vessels, that is, wounds not causing immediate hemorrhage (one case of complete division of the femoral artery and one case of almost complete division of the external carotid) following bullet wounds These two cases differ from those previously reported by Dr Pierre Duval and his collaborators (THE JOURNAL, Nov 25, 1916, p 1613) in the length of time (eight days) that elapsed between the receipt of the wound and the onset of the hemorrhage which led to the discovery of the wound *Although both patients recovered,* Planson again calls attention (agreeing with Duval and Sencert) to the danger of death to which these lesions expose the patient, and the necessity of a thorough systematic exploration of the vessels when the site and the direction of the wound have excited suspicion as to the nature of the lesion

Dr Potherat, surgeon at the hospitals of Paris, since the beginning of the war has frequently observed cases of these wounds—which he prefers to term "stanched wounds"—occurring on almost all the main trunks of the arteries He thinks that many arterial hemorrhages which have been classified as "septic secondary hemorrhages" were in reality arterial hemorrhages caused by trauma but retarded in occurrence by a stanching" or tamponing action How long after the trauma does the arterial wound reveal itself by hemorrhage? It is quite variable Several hours several days, even several weeks elapse Potherat has seen a subclavian artery wound bleed nine days after its receipt—an axillary artery wound after seventeen days—and the artery was almost totally divided How are we to explain these facts? The wound of the artery can be closed 1 By the projectile itself or a vestimentary fragment acting as a stopper The moment the plug is removed the hemorrhage begins 2 The edges of the torn artery and particularly the intima curl up into the lumen of the artery, a coagulum or clot is formed and stops the flow of blood, this clot disintegrates or becomes detached in the course of a dressing and hemorrhage ensues 3 The arterial wound could have produced a localized hemorrhage of little importance too slight to manifest itself externally but sufficient to produce a hematoma, which being compressed against the vessel by the adjacent tissues plugs the wound by compression, and delays the hemorrhage until such time as an inadvertent jar in the course of a dressing of the wound will detach this improvised tampon and hemorrhage occurs

To prevent accidents, sometimes fatal to which these "stanched" wounds of the arteries expose the patients, it is absolutely necessary to make a thorough examination of every case in which the course of the projectile gives cause to suspect a blood vessel wound, even though there is no clinical evidence of this wound If a vascular lesion is discovered, infinitesimal though it may be, immediate ligation of the artery on each side of the lesion should be done, *loco loeso*

Dr Routier observed a patient with a wound in the popliteal space fracture of the inferior extremity of the femur, and intermittent hemorrhages Amputation of the thigh at the middle had to be done on account of gangrene of the leg and foot Dissection of the anatomic specimen revealed a tear in the wall of that portion of the femoral artery lying in Hunter s canal this tear attaining half the caliber of the vessel It probably had been caused by a spicule of bone from the femur It is possible that the interruption of the hemorrhage was due to the artery catching on the point of the fragment, and that hemorrhage occurred at each displacement of the fragment

Dr Bazy some time ago observed a case of wound of the femoral artery caused by revolver shot, in which formidable hemorrhage did not occur until the third day after receipt of the wound This hemorrhage was easily stopped by compression and subsequent ligation of the vessel The patient recovered

Dr Pierre Duval reported a case of complete section of the internal jugular and common carotid by a shell explosion which was operated on successfully by Dr Fiolle

The War

ACUTE ENDOCARDITIS AND PERICARDITIS AMONG THE SOLDIERS AT THE FRONT

Among 1,719 soldiers treated during fourteen months in the contagious disease division of the military health service Drs Nobecourt and Peyre observed that thirty-four (1 97 per cent) were affected with endocarditis and pericarditis Various infectious processes were responsible for one case of mitral endocarditis and three cases of pericarditis Acute articular rheumatism was the cause of thirty of these cases of cardiopathy The mitral valve was always affected and frequently (in nine cases) also the aortic valve Pericarditis was present in nine patients and in five of these there was also an endocarditis Age has had a manifest influence on the frequency of cases of cardiopathy, 62 per cent of the cases occurred among men between 20 and 25 and 14 per cent occurred among men between 32 and 34 Among soldiers between 20 and 22 years of age, rheumatism resulted in cardiopathy in 40 per cent of the cases, between 23 and 30, in 25 per cent and among older men, in 13 per cent On an average of from five to six weeks after dismissal from the hospital these cases were checked up with the following results Out of seventeen cases of mitral endocarditis, eight gave normal sounds, nine showed some signs of mitral disease Among nine cases of aortic endocarditis, five gave normal sounds three gave harsh or clangorous sounds, and one showed the murmur of aortic insufficiency Often cardiomalacia existed Signs of pericarditis had disappeared in all cases In about half the cases, the patients seemed cured, the others still showed signs of endocarditis

UTILIZATION OF WOMEN'S SERVICES IN THE MANUFACTURE OF DENTAL SUPPLIES FOR THE MILITARY HEALTH SERVICE

Owing to the scarcity of male workmen and the necessity to provide prostheses as quickly as possible for soldiers accidentally edentated, the undersecretary of state of the military health service has drawn the attention of those in charge of this special phase of the service to the employment of women who have already rendered valuable aid in other departments It was possible to entrust to women, after a period of apprenticeship lasting from ten to twenty days many phases of the manufacture of prosthetic dental apparatus, such as the casting of plaster models and the making of dental modeling wax, registering teeth, filling casts, finishing and polishing From experience it may be affirmed that a dental laboratory worker, assisted by two well trained women, can double his output of apparatus

Necessity of Publishing the Composition of Pharmaceutical Specialties

Dr Tiffeneau associate professor at the Faculte de medecine de Paris, has drawn the attention of the Societe de medecine legale to the fact that most manufacturers fail to publish the qualitative and quantitative composition of their products The employment of these specialties constitutes a return to empiricism and, moreover, these products escape the control of the service for the repression of frauds After discussion the societe ruled that the composition of these products be declared to a service or bureau designated by the public authorities before they are placed on sale

Election of Two Foreign Associates to the Academy of Medicine

At a recent session the Academie de medecine elected two foreign associates Drs Francisco Durante, professor of clinical surgery at the Faculte de medecine de Rome, and Simon Flexner, of the Rockefeller Institute, New York

Personal

Dr Ferdinand Widal professor of internal pathology at the Faculte de medecine de Paris has been called to take the place of the late Professor Bouchard in the superior council of public instruction

Marriages

James Roy Freeland M D Pittsburgh, to Miss Katherine Palmer Moore of New York City, December 28

Sylvester Guy Pake, M D Superior Wis to Miss Rhea Janet McManus of Duluth, Minn December 19

Frederick Leonard McDaniel M D to Miss Sue McCloskey, both of Osawatomie, Kan, January 15

John Henry Traband, Jr, M D, to Miss Laura Adelaide Hempel, both of Baltimore, January 9

James Clyde Sargent M D, to Miss Mary Genevieve Cook, both of Minneapolis, January 3

William A Hall, M D, Prairie du Chien, Wis, to Miss Lydia Hulse of St Paul, January 4

Julius T Kane M D Jamaica N Y, to Miss Margery L Davis of Montreal, Que, January 6

Russell Arthur Jewitt, M D, Cleveland, to Miss Kate Freund of Chicago, January 16

Edward Estill Johnston, M D, to Miss Mary L White, both of Indianapolis, January 3

Dabney B Reinhart, M D, Merrill, Wis, to Miss Ann Toomey of Chicago, January 1

Harry Edgar Dees M D, Bicknell, Ind, to Miss Naomi Robertine Cox, January 11

William Joffee M D, to Miss Freda Abelson, both of Chicago January 14

Deaths

Charles Francis Withington, M D, Boston, Harvard Medical School, 1881, aged 64, a Fellow of the American Medical Association, and at one time a member of the committee on national legislation, president in 1914 and 1915 of the Massachusetts Medical Society, visiting physician to the Boston City Hospital and a member of the consulting staff of the Boston Insane Hospital, Choate Memorial Hospital, Woburn, Mass, and the New England Hospital for Women and Children, a member of the Association of American Physicians, formerly instructor in clinical medicine in his alma mater and later lecturer of medicine in the Graduate School of Medicine in Harvard University, for several years associate editor of the *Boston Medical and Surgical Journal,* died at his home, January 7, from heart disease

Charles Norman Ellinwood, M D, San Francisco, Rush Medical College, 1858, aged 80, a Fellow of the American Medical Association, formerly surgeon to the San Francisco City and County Hospital, president and professor of physiology and clinical surgery in Cooper Medical College, surgeon of the Seventy-Fourth Illinois Infantry, U S Volunteers, and surgeon major in the army during the Civil War, for many years a surgeon in the United States Marine Hospital Service and one of the organizers of the United States Public Health Service, a member of the board of regents of the University of California, and surgeon in chief to the San Francisco and German hospitals, died at his home, January 4, from senile debility

Chauncey D Palmer, M D, Cincinnati, Medical College of Ohio, Cincinnati, 1862, aged 77, a member of the Ohio State Medical Association, assistant surgeon at Camp Dennison, Ohio, from 1862 to 1865, professor of obstetrics and gynecology in his alma mater from 1869 to 1875, professor of gynecology and clinical gynecology from 1875 to 1906, and emeritus professor of obstetrics, gynecology and clinical gynecology since 1906, clinician in obstetrics and gynecology at the Cincinnati Hospital, from 1883 to 1906, consulting gynecologist to the Presbyterian and Good Samaritan hospitals, Cincinnati, contributor to many textbooks on obstetrics and gynecology, died at his home in Avondale, Cincinnati, January 10

Aaron J Steele, M D, St Louis, Jefferson Medical College, 1859, aged 81, formerly a Fellow of the American Medical Association, a member of the Missouri State Medical Association, and American Orthopedic Association, professor of orthopedic surgery in Washington University, orthopedic surgeon to the Missouri Baptist Sanitarium and consulting orthopedic surgeon to the Martha Parsons Children's Hospital, St Louis, a veteran of the Civil War, died at his home, January 7

John Arthur Cullum, M D, Regina, Sask, University of Toronto, Ont, 1905, L R C P, L R C S (Edin), L R F P & S (Glas), 1906, aged 38, captain in the Canadian Army Medical Corps, who on account of gallantry had been recommended for the Victoria Cross, and had been awarded the Military Cross and the *Croix de Guerre,* died November 10, from wounds received while on active service with the Canadian expeditionary force on the western war front in France

Pitt Yandell McCoy, M D, Evansville, Ind, Rush Medical College, 1863, aged 75, a Fellow of the American Medical Association, and a delegate from Kentucky to the Association at its meeting in St Louis in 1873, formerly professor of surgery in Evansville Medical College, president of the staff of St Mary's Hospital, and for thirty-five years division surgeon for the Louisville and Nashville System, died at his home, January 14, from heart disease

George Albert Ickes, M D, Altoona, Pa, Jefferson Medical College, 1886, aged 61 formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of Pennsylvania, for many years a member of the city council, and president of that body in 1901, at one time coroner of Perry County, died in the Altoona Hospital, January 9, from pneumonia superinduced by a fall, December 31

W Franklin Coleman, M D, Chicago, Queens University, Kingston, Ont, 1863, M R C S (Eng), 1870, aged 79, formerly a Fellow of the American Medical Association, one of the founders and president of, and professor of ophthalmology in the Post-Graduate Medical School of Chicago, well known as a specialist in diseases of the eye, ear, nose and throat, died in Hastings, Fla, January 22

Alfred Myers, M.D, York, Pa, Jefferson Medical College, 1875, aged 62, a member of the Medical Society of the State of Pennsylvania, postmaster of Hampton, Pa, during the administration of President Benjamin Harrison, died in his laboratory, January 5, from cerebral hemorrhage. The York County Medical Society held a special meeting, January 6, to take action on the death of Dr Myers

Eugene Boyd Campbell, M D, Williamsport, Pa, Jefferson Medical College, 1873, aged 66, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of Pennsylvania, for several years physisian to the Williamsport City Hospital, and for four years president and for four years secretary of the hospital board, died at his home, January 6

Albert A Seem, M D, Bangor, Pa, Jefferson Medical College, 1865, aged 73, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of Pennsylvania, surgeon of U S Volunteers during the Civil War, chief burgess of Bangor, a member of the borough council and school board and for several years president of the Bangor Trust Company, died in Los Angeles, January 5

Seth Louis Lloyd, Williamstown, Mass (license, Massachusetts years of practice, 1894), aged 51, for several terms a member of the board of selectmen and school committee of Williamstown and later a member of the board of commissioners of Berkshire County, superintendent of the Sand Springs Sanatorium, died at his home, January 7

Charles Richard Charteris, M D, Chatham, Ont., University of the Victoria College, Coburg, Ont, 1887, aged 51, a member of the Ontario Health Association, acting medical officer of health of Chatham and Chatham Township, past president of the Chatham Ont, public library board, died at his home, November 25, from angina pectoris

Henry August Kornemann, M D, Newark, N J, College of Physicians and Surgeons in the City of New York 1872, aged 83; a Fellow of the American Medical Association and a member of the American Public Health Association, for many years a member of the staff of the German Hospital, New York, died at his home, January 8

Stephen Olney, M D, Sioux Rapids, S D, Western Reserve University, Cleveland, 1868, aged 70, formerly a member of the South Dakota State Medical Association, a practitioner of Sioux Falls, from 1877 until his retirement in 1911, died at his apartment in the Hotel Kaiserhof, Sioux Falls, January 6, from acute dilatation of the heart

Harry Burdell Sanford, M D, Memphis, Tenn, Memphis (Tenn) Hospital Medical College, 1896, aged 40, formerly a member of the Tennessee State Medical Association, Mississippi Valley Medical Association and Tri-State Medical Association of Mississippi, Arkansas and Tennessee, died at his home, January 8, from tuberculosis

Clinton G Gray, M D, Ironton, Ohio, Miami Medical College, Cincinnati, 1871, aged 71, formerly a member of the Ohio State Medical Association, a veteran of the Civil War, for nineteen years proprietor of Gray Gables Sanatorium Hanging Rock, died in the Ohio State Hospital, Dayton January 4

Thomas B Taylor, M D, St Louis, Washington University, St Louis, 1876, aged 67, a member of the Missouri State Medical Association, formerly surgeon to the Mississippi River and Bonne Terre Railway at Festus, Mo, and coroner of Jefferson County, died in the Masonic Hospital, St Louis, January 9

Lester Elmer Peck, M D, Buchanan, Mich, University of Michigan, Homeopathic Medical School, Ann Arbor, 1894, aged 46, health officer for several years, a member of the village council for four years and president for three terms, died at his home, December 30, from carcinoma of the stomach

Henry Laning, M D, Chevy Chase, Md, Albany (N Y) Medical College, 1864, aged 73, who had spent the greater part of his life since 1873 in Osaka Japan, where he was for forty years head of St Barnabas Hospital, died at the home of his son in Chevy Chase, January 1, from cerebral hemorrhage

Frank Rattan, M D, Martinez, Calif., Cooper Medical College, San Francisco 1885, aged 59, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of California, died at his home, January 3

Ambrose Jones, M D, Delton, Wis, Rush Medical College, 1849, aged 96, a pioneer in telegraphy, who sent the first message between Milwaukee and Chicago on Jan 15 1848, assistant surgeon of the Fifth Wisconsin Volunteer Infantry during the Civil War, died at his home, January 11

James H Hedgpeth, M D, Rockport, Mo, College of Physicians and Surgeons, St Joseph, Mo, 1882, aged 61, for several years coroner of Atchison County, Mo and for eight years general manager of the Rockport Langdon and Northern Railroad, died at his home, about January 5

James Logan Brown, Pleasant Unity, Pa (license twenty years practice 1881, Westmoreland County Pa), aged 72 formerly a member of the Medical Society of the State of Pennsylvania and for forty-five years a practitioner of Pleasant Unity, died at his home January 13

John H Williams, M D, Summerfield Ohio Columbus (Ohio) Medical College 1885, aged 60 a member of the Ohio State Medical Association after a violent quarrel with his wife January 5 shot and killed her and afterward shot himself dying from his injuries January 6

Samuel Watson McConochie, M D, Hamilton Ont, Trinity Medical College Toronto 1883 L R C P (Lond) 1884, aged 60 died in the City Hospital Hamilton October 11 from the effects of an incised wound of the throat self inflicted it is believed with suicidal intent

Noble Theodore Jerman, M D, Holmesburg Philadelphia Hahnemann Medical College Philadelphia, 1873 aged 66 formerly a member of the school board and founder and president of the Holmesburg Improvement Association died at his home January 8

David Chancellor Boyce, M D, Pittsburgh University of Pennsylvania Philadelphia, 1892, aged 49, a Fellow of the American Medical Association, surgeon of the Northwest division of the Pennsylvania Lines, died at his home January 12 from pneumonia

James T Warren, M D, Sprague Mo, Washington University St Louis 1871 Jefferson Medical College 1882, aged 69 a pioneer practitioner of Bates County Mo died at the home of his daughter in Minneapolis Kan November 19 from arteriosclerosis

George Albert Steele, M D, Havana N D, Rush Medical College 1895, aged 44 formerly a Fellow of the American Medical Association local surgeon of the Great Northern System died on a train near Colorado Springs January 10 from tuberculosis

Thomas William Fingland Macknight, M D, Tamworth Ont Queens University Kingston Ont 1913 aged 29 a Canadian medical volunteer officer on duty with the Royal Army Medical Corps in India died in Bombay September 4 from pyrexia

Samuel Rideout Glover, M D, Midway Mills Va Medical College of Virginia Richmond 1907 aged 47 a member of the Medical Society of Virginia, died in the Stuart Circle Hospital, Richmond December 5 from pernicious malaria

Ellsworth Smith Adams, M D, Beverly N J Jefferson Medical College 1890 aged 42 formerly a member of the Medical Society of the State of New Jersey and mayor of Beverly, died at his home January 5 from heart disease

Hannibal Landon, M D, Remington Ind Starling Medical College Columbus Ohio 1865 Jefferson Medical College 1866, aged 75 for forty years a practitioner of Jasper County Ind died at his home, January 6 from asthma

Clarence M Kuykendal, M D, Rock Hill, S C, University of Maryland Baltimore 1890 aged 48 who retired from practice several years ago to take charge of the Kuykendal Drug Company died in Rock Hill, January 5

Louis Watson Raison, M D, Altoona Pa, Medical College of Ohio Cincinnati 1884, aged 63 for several years surgeon for the Baltimore and Ohio System at Foxburg, Pa died at his home January 5 from bronchopneumonia

Herbert Hallet Marsh, M D, Chillicothe Ohio, Ohio Medical University Columbus 1896 aged 46 formerly a Fellow of the American Medical Association died at his home, December 25 from pneumonia

Elmer A Clarke, M D, Los Angeles Homeopathic Hospital College, Cleveland 1878, aged 68 a member of the board of health of Los Angeles in 1909 died at his home, December 31 from pneumonia

Clinton E Sapp, M D, South Omaha, Neb Medical College of Ohio Cincinnati, 1875, aged 64, formerly a Fellow of the American Medical Association, died at his home October 11, from chronic nephritis

Wyman H Fisher, M D, Wanatah Ind, Northwestern University Medical School, Chicago, 1880, aged 72, for forty years a practitioner of Laporte County, Ind, died at his home, January 5, from nephritis

John Adams Winters, M D, LaCrosse, Wis, Bellevue Hospital Medical College, 1883 aged 60, was found dead from heart disease in his office in the State Bank Building LaCrosse, January 2

Thomas George Rainey, M D, Cleveland, University of Michigan Ann Arbor 1872 aged 71, died at his home December 20 from injuries received in an automobile accident in September last

Henry D Fulton, M D, Pittsburgh, Jefferson Medical College 1883 aged 57, a member of the Medical Society of the State of Pennsylvania, died at his home, December 27, from pneumonia

John Locke Hardeman, M D, Porterville Calif Washington University St Louis 1878 aged 61 a pioneer orange grower of the Porterville district died at his home, December 24 from valvular heart disease

John Patrick Moore, M D, Long Island City N Y, University of Vermont Burlington 1894, aged 50 died at his home in Astoria Long Island City October 24 from uremia

George A Anderton, M D, Greystone Park N J Baltimore Medical College 1907 aged 35 assistant physician at the Morris Plains (N J) State Hospital, died January 2

Granville W Traylor, M D, McCune, Kan, Kansas City (Mo) Medical College 1901, aged 39, a member of the Kansas Medical Society died at his home January 1

James Willard Avery, M D, Delaware Ohio Miami Medical College Cincinnati 1883 aged 58, died at the home of his sister in Delaware December 31, from carcinoma

Henry A Lounsbury, M D, Detroit, Detroit College of Medicine and Surgery, 1888 aged 53, died in the Receiving Hospital Detroit, December 29 from pneumonia

Oscar Jerome Shepardson, Chester Mass (license, Massachusetts years of practice 1894) aged 65 died in the Springfield Hospital November 24 from brain tumor

John W Koelle, M D, Jamestown Mo Homeopathic Medical College of Missouri St Louis 1896, aged 47, died at his home December 23 from pneumonia

Nathan F Canaday, M D, Hagerstown Ind Homeopathic Hospital College Cleveland 1870, aged 72 died at the home of his son in Newcastle Ind January 5

W F Rogers, Porterville Miss (license Mississippi) aged 62 a trustee of the Matty Herse Hospital, died at his home December 11 from pneumonia

James Harmer Rile, M D, Wilmington, Del Hahnemann Medical College, Philadelphia 1879, aged 59 died at his home January 2 from pneumonia

N Herbert Haight, M D, Sacramento Calif Hahnemann Medical College Chicago 1890 aged 53, died at his home December 29 from heart disease

George F Smith, M D, Carthage Mo, Louisville (Ky) Medical College, 1871 aged 68 died in Nevada, Mo, December 8 from cerebral hemorrhage

Amos Lewis Sweet, M D, Geneva N Y, New York University New York 1866, aged 73 died at the home of his son in New York, January 1

Joseph J Andzulatis, M D, New Britain Conn, College of Physicians and Surgeons, Baltimore 1894, aged 51, died at his home December 29

Peter S Weidman, M D, Edwardsville Ill Albany (N Y) Medical College 1855, aged 90 died in the Jacksonville State Hospital January 3

George W Irick, M D, Sheridan Ark Physio-Medical College of Indiana Indianapolis 1890 aged 66, died at his home, December 21

Bernard H Walker, M D, Norfolk, Va, Jefferson Medical College 1849, aged 91 died at the home of his son in Norfolk Va January 1

Erasmus D Hall, M D, Knowlesville, N Y, Castleton (Vt) Medical College 1853 aged 85, died at his home, December 9

George T West, Bancroft, Iowa (license years of practice Iowa 1866), aged 69, died at his home, December 11, from pleurisy

Robert Thomson, M D., Troy N Y, Albany (N Y) Medical College, 1871, aged 70 died at his home, December 24

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

NORTH CAROLINA TO THE FORE

The New Governor Backs Up the State Board of Health in Its Fight on Fraudulent Nostrums

Conservation of the public health and protection against the menace of the fraudulent "patent medicine" business bid fair to be accomplished facts in North Carolina The Board of Health of that state has for some time distinguished itself as being progressive in its attitude and aggressive in its methods The Old North State now has the additional advantage of having in its governor's chair a man who realizes how great an asset to the commonwealth is the health of the people Thomas Walter Bickett, a distinguished lawyer and the son of a country doctor, was, on Jan 11 1917 inducted into a four years' term as governor of North Carolina Governor Bickett in his inaugural address displayed a conception of the work of modern medicine that it as gratifying as it is encouraging His remarks relative to the State Board of Health and the efforts of the medical profession indicated an intimacy with the ideals of scientific medicine, preventive and curative Especially interesting were Governor Bickett's remarks on the problem of fraudulent nostrums To quote from a newspaper report of the address

> 'The State Board of Health deserves the unqualified support of the general assembly in its campaign against quacks and quackery The law requires a man to have a diploma from a first class medical college and to stand a rigid examination before the North Carolina Board of Medical Examiners before he is allowed to write a single prescription for a patient in North Carolina And yet we permit the sale of nostrums to our people without any adequate knowledge of whether or not they are injurious to health, or have any medicinal value whatever
>
> I am in favor of a law making it a felony for any man to sell offer for sale or advertise for sale in North Carolina any proprietary or patent medicine purporting to cure cancer consumption diabetes paralysis epilepsy Bright s disease, or any other disease for which the North Carolina Medical Association and the American Medical Association declare that no cure has been discovered
>
> I am earnestly in favor of a law requiring all vendors of proprietary medicine to file with the State Board of Health a statement showing the exact composition of such medicines and that the State Board be empowered to forbid the sale of such proprietary medicines in the state of North Carolina, if in its opinion it is without curative value in the treatment of the disease it purports to cure
>
> A bill is being prepared by our health department that will deal fully and adequately with this subject, and I give to this bill my most emphatic endorsement

A BAG OF FERTILIZER and A BOTTLE OF DOPE

One is for a plant	The other, for a child
One is required by law to print its ingredients on the package	The other is not required to disclose its ingredients
One can be used intelligently, in accordance with scientific knowledge regarding the effects of the substances on plants	The other cannot be used intelligently in accordance with scientific knowledge regarding the effects of the substances on human beings
One thrives upon openness and public intelligence	The other thrives upon secrecy and public ignorance
One defrauds with difficulty	The other defrauds with ease
For the one the Government, knowing its composition can furnish the comsumer exact information as to its effects	For the other, the Government not knowing its composition cannot furnish the consumer any statement regarding its effects

Is It Just and Right That the Farmer May Know What He Gives His Plants, and Unjust and Wrong to Allow the Parent to Know What He Gives His Child?

North Carolina in its January *Health Bulletin* presents the interesting parallel given above, between the requirements in that state for selling fertilizers and 'patent medicines respectively

Governor Bickett's statement that he favors a law that will permit the people of North Carolina to know what they are taking when they prescribe for themselves, is in line with the attitude already taken by the North Carolina State Board of Health That board devoted its January, 1917, *Health Bulletin* to a discussion of "The 'Patent Medicine' Business or, Accurately Speaking, The Secret Remedy Business" This twenty-four page pamphlet contains so much of interest that it should be put into the hands of every citizen of North Carolina[1] On the cover a parallel is drawn—we reproduce it on this page—between the North Carolina requirements for the sale, respectively, of fertilizers and "patent medicines" The Board of Health calls attention to the distinction between patented medicines and what are colloquially known as "patent medicines" It emphasizes the fact that a patented medicine is an open formula medicine, a product that is non-secret, while the "patent medicines" are almost invariably secret in composition and depend for their popularity on the mystery which this secrecy permits and encourages The work of the "Select Committee on Patent Medicines" in Great Britain is summarized and some interesting extracts from the committee's report are published in detail A chapter on "Tricks of the Trade" discusses such tricks as "The Story of Extraordinary Origin of an Ordinary Prescription," "The Aliases of Secret Remedy Venders," "The Cooperative Mailing List," "Blackmail in the Purchase of Abortion-Producing Remedies," and others

In discussing the problem of the responsibility of newspapers for some of the evils of the "patent medicine" business, the Board of Health emphasizes the fact that abolishing secrecy will result in protecting the press The chapter on the "Explanation of Public Confidence in the Secret Remedy" is thought-provoking and will give the layman some new viewpoints The psychology of advertising, the deep seated superstitions, especially of the ignorant, which are played on through the secret and therefore mysterious nostrum, the tendency of human nature to confuse a sequence of events with cause and effect and, finally, the physiologic action of the powerful drugs that are to be found in some nostrums are all discussed in explaining why secret remedies are used to such an enormous extent

In closing, the North Carolina State Board of Health calls attention to the fact that a law requiring the "patent medicine" manufacturer to put the names and quantities of the active ingredients of his product on the label will not spell the ruin that the 'patent medicine' fraternity has declared, unless, indeed, the products are worthless and fraudulent The *Health Bulletin* specifically mentions the case of the manufacturers of "Ayer's Sarsaparilla," etc, who for years have published a complete quantitative and qualitative formula on the labels of their products

If the bill which is being prepared by the North Carolina State Board of Health requires that all "patent medicines" sold in North Carolina shall bear on their labels the names and amounts of their active ingredients there will be an interesting fight The "patent medicine" interests may be counted on to oppose such a bill tooth and nail for reasons that we have repeatedly stated, viz, that the bulk of the "patent medicine" business is inherently fraudulent and cannot stand the light of publicity If such a bill finally passes, North Carolina will have achieved the notable distinction of being the first state in the Union adequately to protect its citizens against the fraudulent nostrum business New York City and the state of Louisiana have both attempted similar legislation, the former through its commissioner of health, the latter through the state board of health The New York ordinance while enacted more than a year ago, has been rendered practically inoperative by the legal fight made by the 'patent medicine" interests on it The ruling of the Louisiana Board of Health, apparently, never passed the academic stage

---

[1] The Bulletin will be sent free to any citizen of the state on request Address Dr W S Rankin, Secretary State Board of Health Raleigh, N C

PIL CASCARA COMPOUND-ROBINS

Report of the Council on Pharmacy and Chemistry

A circular issued by the A H Robins Company of Richmond, Va contains the following statement

> PIL CASCARA COMPOUND-ROBINS is a rational therapeutic formula composed of CASCARA PODOPHYLLIN COLOCYNTH and HYOSCYAMUS which promotes a natural flow of secretions, which is, in turn the physiologic stimulant of peristalsis Thus a normal evacuation is produced without subsequent inhibition
>
> They contain no Mercury Strychnia nor Belladonna
>
> An ideal aid to any remedial agent when a Mild Medium or Strong alimentary timulant is needed [*sic*]
>
> Made in two strengths the dosage may be easily regulated so as to obtain the effects of an Anti Dyspeptic Aperient Laxative or Cathartic as desired They never cause discomfort unless given in larger dose than needed

This preparation is another example of the innumerable mixtures of well-known drugs having nothing in the way of originality or of special therapeutic value to recommend them

The advertising implies that this particular combination has a special action on the secretions of the gastro intestinal tract otherwise it would be hard to explain the claim that the preparation is antidyspeptic, if that means anything more than a laxative or cathartic

The claim is made that this preparation contains no belladonna—yet it admittedly contains hyoscyamus! This manifests either ignorance on the part of the manufacturers or an effort to impose on the medical profession Both belladonna and hyoscyamus contain variable amounts of similar alkaloids chiefly hyoscyamin Hyoscyamus is feebler than belladonna in its action as it contains less alkaloid The qualitative differences between the two drugs with reference to their use as laxatives is so slight as to make the company s claim for hyoscyamus appear either deliberately misleading or to be the result of crass ignorance Promoting this mixture of well-known laxatives and cathartics as an ideal aid to any remedial agent when a mild medium or strong alimentary stimulant is needed" is a slur on the intelligence of physicians

Pil Cascara Compound Robins is not acceptable for New and Nonofficial Remedies

Editorial Note—Advertisements of Pil Cascara Comp-Robins appeared in the following medical journals during 1916

American Journal of Surgery
Maryland Medical Journal
Charlotte Medical Journal
Medical Council
Southern Practitioner
Virginia Medical Semi Monthly
Texas Medical Journal
Medical Herald
Medical Brief

CASTA-FLORA

Report of the Council on Pharmacy and Chemistry

Casta-Flora is one of those complex preparations which are offered to the medical profession with plausible arguments in support of the claims made It is put out by the Wm S Merrell Chemical Co, Cincinnati Each fluidounce is said to represent

> Castanea fresh leaves 40 gr Passiflora fresh plant 40 gr Gelsemium green tincture 8 minims Inula represented by the camphoraceous stearoptene Helenin 20 grs Iodized Lime 8 gr Menthol 1 4 gr Aromatic Syrup Yerba Santa 60 minims

It is said to be

> A new combination of well tried remedies of especial value in pertussis and other spasmodic coughs It is composed of astringent antispasmodic sedative and expectorant agents that control the paroxysms relieve the irritation promote expectoration and give tone to mucous membranes involved

Still more exaggerated claims are made for the individual constituents of Casta-Flora partly by direct statement, partly by inference For example

> Castanea is almost a specific in whooping cough and other spasmodic coughs
>
> Passiflora is a narcotic, sedative and antispasmodic without habit forming properties nor does it lock up the secretions and upset digestion like opiates
>
> Inula (elecampane) has been employed as a cough remedy in England for centuries Its action is similar to guaiacol and creosote Its active principle, helenin is destructive of tubercle bacilli in dilutions of 1 to 10 000
>
> Iodized Lime Menthol and Yerba Santa are too well known as expectorants and antiseptics to require more than passing mention

That Casta-Flora is a new' combination may be admitted, it is improbable that exactly this combination of obsolete drugs was ever before selected for any purpose whatever, but the statement is misleading in that no new principle of therapeutics is involved On the contrary, the combination is just what might be expected from haphazard choosing of discarded and nearly forgotten drugs It seems incredible that a reputable firm of manufacturing pharmacists would make the positive statement that castanea is *almost* a specific in whooping cough Why not say it is a specific? It would be about as true A specific or 'almost specific" for this disease would rank among great medical discoveries, but castanea is merely a slightly astringent drug neither better nor worse than scores of other astringent drugs that have been tried found valueless and discarded

Hardly less surprising are the statements regarding passiflora This herb has been on the market about three quarters of a century Not only has it never established itself in scientific medicine but it is not even mentioned in modern standard works on therapeutics

Of all the statements made in the circular perhaps the most remarkable, in that it is so dangerously misleading, is that regarding helenin, the active principle of elecampane The statement that this principle (helenin) is destructive of tubercle bacilli in dilutions of 1-10,000 can only mean that it is of extraordinary value in the treatment of tuberculosis, in fact, it is definitely stated that the action of elecampane is similar to that of guaiacol and creosote

It is obvious that any drug which would destroy the tubercle bacilli in the human lungs without exerting a toxic action on the patient would be a great contribution to medicine But although elecampane may have been used for centuries it has proved to have little if any, merit and even the National Standard Dispensatory, p 848 says Elecampane was formerly employed as a tonic, stimulant, diuretic, diaphoretic expectorant and emmenagogue, but has now largely fallen into disuse One looks in vain in the standard textbooks on therapeutics for a description of the uses of inula (or elecampane) and of its so-called active principle, helenin

The circular to which reference has been made says, referring to the use of castanea and passiflora in the treatment of whooping cough

> Gelsemium when made from the fresh green plant—as is Merrell s—is an excellent adjuvant to the above drugs and allays the nervous irritability so frequently present

H C Wood Jr (Pharmacology and Therapeutics, 1916 p 160), says of gelsemium Gelsemium was originally employed as an arterial sedative and febrifuge in the malarial fevers of the South and subsequently in sthenic fevers It appears in some way to depress the bodily temperature, but it does not appear probable that any advantage to be derived from it will counterbalance the danger attending its employment in the large doses required In asthma spasmodic laryngitis, whooping cough, and nervous cough it has been recommended by Bartholow, but is little used '

That is about as favorable a statement for the drug as is to be found in the textbooks and it serves to illustrate how little new there is in this mixture of obsolete drugs that Merrell seeks to market as one possessing extraordinary therapeutic value

Even though the ingredients, or certain of them, were singly useful in the treatment of those conditions for which Casta-Flora is recommended no one could possibly foresee the effect in any given case of such a jumble of drugs, both active and inert, as is said to be represented in this preparation The prescribing of such mixtures, the action of which cannot in any way be foreseen is plain charlatanism

In addition, the various drugs in Casta-Flora are present in such proportions that the dose of each of the several ingredients bears no relation to the commonly accepted dose

Casta-Flora is not acceptable for New and Nonofficial Remedies

Editorial Note—Advertisements of "Casta-Flora" appeared in the following medical journals during 1916

A Standard Size for Medical Books

To the Editor—I am writing to make a suggestion in regard to the size of medical books The first thing one notices on going into a lawyer's office is the uniform size of the books on his shelves The first thing one notices on going into a physician's office is the jumbled up appearance of his books, owing to the fact that nearly all of them are of different heights and widths I believe that the American Medical Association should take the lead and start a movement to have a standard established for the height and width of all medical books They should be of one height and width, but may be thick or thin as necessary This would give us a library which would make a decent appearance and would save our friends the bother of asking us, after looking at our books, whether we are moving in or moving out

Yellow Petrolatum—Vesicorectal Reflex—The Treatment of Intestinal Stasis

To the Editor—To those who believe, as I do, that some form of lubrication of the large intestine is desirable in the treatment of autointoxication from intestinal stasis, let me recommend common yellow petrolatum in place of oil injections or of liquid petrolatum by the mouth From 1 to 4 heaping teaspoonfuls a day, by mouth, will generally produce soft or semiliquid stools without the least griping It is decidedly more efficacious than the liquid petrolatum, which frequently passes right by fecal masses without mixing with them or causing their expulsion, while the yellow petrolatum mixes thoroughly with the bowel contents and is never expelled by itself This also makes it a much more decent form of treatment than that by liquid petrolatum, which often causes a most disagreeable leakage The yellow petrolatum has somewhat of the latter advantage over the oil injections, to say nothing of what it saves in fuss and expense An oil enema is so elaborately disagreeable a function that I often wonder how many of the men who light-heartedly order their patients to inject half a pint of olive oil every night for a year or so have ever tried it themselves As to the expense, a 5 pound can of the yellow petrolatum retails for a dollar, and this will last from two to three times as long as a gallon of cottonseed oil, costing about twice as much, or if olive oil is used, from three and a half to four times as much The white petrolatum costs more than the yellow and is, I believe, less efficacious The yellow is practically tasteless, and if approached without prejudice is really a rather pleasant dose If so preferred, it can be taken in any hot liquid The dose necessary at first can generally be reduced by half after a week or so

Another aid in the treatment of constipation is the vesicorectal reflex Some years ago I noticed that if, perforce, micturition had to be postponed until the desire was acute, the bowel often would also move if the opportunity were given it, and by making systematic use of this reflex I was able, after having been a slave of the pill for twenty years, to go without any laxative whatever This reflex accounts for the efficacy of drinking a pint of water at bedtime The common supposition seems to be that some of the water passes clear through and irrigates the colon from above, but this seems highly improbable What the water does do is so to distend the bladder that the bowel is stimulated to unwonted activity I think the same reflex even without the water drinking at night is one of the factors in the normal morning movement of the bowels In practice, the best method of using it is to take 2 or 3 glassfuls of water at bedtime Then on arising, instead of urinating at once, wait until the desire is quite strong when, if the attempt is made, the bladder and the bowels can generally be emptied together So far as I can learn, physicians and physiologists have paid little or no attention to the vesicorectal reflex, but it certainly exists and can be utilized in the treatment of constipation, either by itself or in connection with other measures

Harold Gifford, M D, Omaha

Request for Report of Results of Percy Method in Treatment of Uterine Carcinoma

To the Editor—I am anxious to get reports from surgeons who have had experience with the Percy heat coagulation method in the treatment of inoperable uterine carcinoma I expect to report my results in the use of this technic before the section on Obstetrics, Gynecology and Abdominal Surgery at the New York session of the American Medical Association I shall be pleased to furnish blanks which cover the form of inquiry that I consider important in order to learn the true value of this treatment in uterine carcinoma I shall highly appreciate any information that may be given me along the lines of this investigation

THE RELIEF OF CONSTIPATION

To the Editor—In Queries and Minor Notes, please enlighten me on the following questions

1 What is the best laxative to be taken continually by tuberculous patients who are confined most of the time in bed, when proper dieting does not seem to give a satisfactory evacuation each day?

2 Is it not better to give a laxative to most tuberculous bed patients as a routine than to run the risk of toxic symptoms of constipation and the chance of rectal troubles as hemorrhoids fissures and fistulas which are common in this class of patients and which, when acquired are hard to get rid of?

3 What is the best laxative in these cases? And should one be given continuously or alternated as for example agar for a while and then liquid petrolatum?

4 I notice that some brands of liquid petrolatum retail for about half the price of others Is there any difference in quality as to effect?

5 Are any pathologic changes produced from the continuous use of liquid petrolatum for months or years?

Kindly omit name and address T R P

Answer—1 There is no "best laxative" to be taken in general by patients with any certain disease Laxatives, like other drugs, should be given to suit the particular condition of the individual patient

2 It is impossible to answer such a general question Again it may be stated that patients must be individualized and not treated by rule

3 See answers to 1 and 2

4 There are differences between various brands of liquid petrolatum The price does not indicate the quality A brand complying with U S P standards for liquid petrolatum should be used

5 So far as known, no pathologic changes resulting from the use of liquid petrolatum have been described

In general it may be said that the aim should be, even with a tuberculous bed patient, unless it is a hopeless case, to relieve constipation by remedial agents other than drugs Diet is here all important Cooked and raw fruits, coarse cereals, vegetables, nuts, cream, butter, oil, bran bread, etc, may be of service Persistence in regulative diet, with attention to details, is imperative Enemas, such as the oil enema at night, may be helpful Massage may be beneficial

The objection to giving a laxative continually is that it induces a habit This is of course not comparable in its harmful effects to the morphin or cocain habit but its ultimate result is apt to be the depriving of the intestine of its power of independent action, the bowels unless urged become more and more sluggish and the dose must be increased Besides there often results an irritable and inflamed intestinal mucosa, the cause of occasional looseness of the bowels mucus in the stools, abdominal pain—a 'cathartic ileocolitis" This really causes much suffering is provocative of many nervous disturbances and may even simulate and be treated for such conditions as appendicitis

So to repeat, we should advise our correspondent to try by every means not to use a laxative even a best laxative as a routine measure The relief from the habit of constipation is at the expense of a new habit, that of cathartics with its attendant irritated bowel

---

EFFECT ON ETHER AND CHLOROFORM OF EXPOSURE TO THE AIR

To the Editor —1 Please tell me if ether is rendered unfit for anesthesia if it is allowed to remain in an open can for some time Does it undergo any chemical change when exposed to the air?

2 Please give me the same information about chloroform

C Mayfield M D *Hutchinson Kan*

Answer—1 Yes The U S Pharmacopeia requires that ether be preserved in partially filled, well closed containers in a cool place remote from fire and protected from daylight The U S Pharmacopeia further cautions that when ether is to be used for anesthesia it is to be dispensed only in small, well closed containers and is not to be used for this purpose if the container has been opened longer than twenty-four hours Ether is slowly oxidized by the action of air moisture and sunlight with the formation of peroxids

2 The U S Pharmacopeia requires that chloroform be preserved in well stoppered bottles in a cool place, protected from light Chloroform which contains alcohol as a preservative is not readily decomposed by exposure to air Worth Hale (Variations in the Toxicity of Chloroform for Anesthesia Annual Reports of the Therapeutic Research Committee of the Council on Pharmacy and Chemistry 1915 p 112) studied the toxicity of four commercial brands of anesthetic chloroform and one sample of anesthetic chloroform which had been standing in the laboratory exposed to the light for at least two years in a half filled white glass bottle He did not discover any marked difference in the toxicity of the five specimens of chloroform examined

LAFAYETTE MIXTURE

To the Editor —What is the composition of Lafayette s mixture used on the border for the treatment of gonorrhea A soldier back from the Texan border showed me the prescription

E C Cary M D Reedsville Wis

Answer —Lafayette mixture is the alkaline copaiba mixture which had considerable vogue about thirty years ago when gonorrhea was treated in a haphazard way It has been characterized recently by pharmaceutic authorities as disagreeable, irrational and usually inefficient The formula is still to be found in the National Formulary under 'Mistura Copaibae' with Lafayette mixture as a synonym The formula is

Copaiba	125 c c
Spirit of nitrous ether	125 c c
Compound tincture of lavender	125 c c
Solution of potassium hydroxid	32 c c
Syrup	300 c c
Mucilage of acacia a sufficient quantity to make	1 000 c c

ACTION OF STRYCHNIN ON BLOOD PRESSURE

To the Editor —What influence if any does strychnin exert on blood pressure?

L W Wright M D Williamsport Pa

Answer —Strychnin in therapeutic doses causes a rise in blood pressure This is principally due to stimulation of the vasomotor centers but in part to the increase in tone of the skeletal muscles Strychnin has *little or no action directly* on the heart and the pulse rate is if anything slowed In quantities large enough to cause convulsions, the rise of blood pressure during the latter is enormous Experiments on animals show that this rise is not entirely due to the convulsion itself, but in part to the effect on the vasomotor center It is rapidly followed by a fall of pressure from overstimulation and fatigue

COMBATING VENEREAL DISEASES

A report on venereal disease (*Munchener medizinische Wochenschrift,* 1916, **63,** 1691) has just been issued by a special committee appointed by the Munich Aerztliche Verein, a medical association, to study questions affecting the preservation and promotion of racial vigor (*Volkskraft*). Venereal diseases, it states, are "next to alcohol and tuberculosis the most dangerous enemies of the human race. The knowledge of this seems to be gradually making its way into wider circles. There is now hope that the importance of this hitherto much neglected field will gradually come to be appreciated. The time has arrived for rousing the community to more energetic measures. It is self-evident that with diseases which are so amenable to treatment as the venereal diseases, everything depends on getting all the persons affected to take thorough treatment. With this, and only with this, is it possible to restrict the spread of these plagues, the prevalence of which is suspected only by the few.

It is a known fact that, at present, persons with venereal diseases in the overwhelming majority of cases get inadequate treatment. This, experience has shown, is due less to the fact that they do not seek medical aid as that they think they are cured as soon as the acute manifestations have subsided. They think that they are cured, or at least they do not regard it as worth while to take further treatment. Syphilitics seldom find it convenient to repeat the course of treatment necessary for a cure unless unmistakable recurrence of the manifestations drives them to a physician. For these reasons the Aerztliche Verein of Munich advocates in the most forcible manner legislative measures to insure that persons affected with venereal diseases get treatment and, especially, that they are kept under treatment and under medical control until they are cured and no longer a menace to others. The carrying through of adequate treatment seems impossible, however, so long as it is optional for the heedless, the unreasonable or the indifferent to let themselves be treated or not. It is therefore essential that the authorities should be empowered to compel those with venereal disease to take proper and adequate treatment. As a logical corollary, the authorities must know what persons they are to compel to take treatment. Compulsory treatment therefore presupposes compulsory notification.

LEGISLATION ADVOCATED

"The Munich Aerztliche Verein therefore advocates legislative provision for compulsory notification and compulsory treatment of venereal diseases. The association does this only after mature deliberation and weighing of all the reasons for and against such a measure. It is well aware that this conflicts with widespread and apparently well founded considerations. But examination of the latter more closely shows that they cannot be regarded as unimpeachable. The chief objection is that compulsory notification would prevent those affected from seeking the aid of a physician. They would either apply to quacks or let their disease go untreated. That the latter would not occur is guaranteed by the pains and fear of the disease, which would be more and more effectual the more the public is enlightened on the subject of venereal diseases. Even now nearly all affected apply for treatment so long as there are appreciable manifestations of the disease. The quacks could be prohibited from treating venereal disease, as the military authorities have now enforced, or, if this proves impracticable, they would have to conform to the regulations in regard to compulsory notification. With energetic measures on the part of the authorities any failure to comply with the regulations would be a difficult and expensive matter. Of course any physicians failing to comply with the regulations would also be liable to penalty.

"The objection that regulations of this kind would encounter invincible opposition on the part of the people seems to be unfounded. Wide and influential circles are of the same mind as our association in this matter, as has been ascertained by written and verbal communications from various quarters. To assume that the medical profession would not do this service for the public welfare is to discredit our profession. It is a favorable circumstance that, just at present, in the consulting dispensaries for venereal diseases which have been organized recently under the auspices of the insurance societies (Landesversicherungsanstalten) throughout the entire empire, we have an arrangement along the same lines. Unfortunately, they are dependent on and subject to the good will of those affected. They have no means of compulsion, and consequently they only half fulfil their purpose. The fact that these consulting dispensaries have received such a welcome everywhere is a sign that the current is flowing in our direction.

"Of course the introduction of compulsory notification and compulsory treatment is an innovation and an experiment, for everything that has been done in this line in other lands has been only half measures. But unless experiments are made, there can be no progress."

REGULATION FOR COMPULSORY NOTIFICATION

The report then outlines the principles on which the regulations for compulsory notification and compulsory treatment should be based. It calls for notification of gonorrhea of the urinary and sexual organs, conjunctiva and rectal mucosa, for ulcus molle, and for syphilis in the first or second phase and in the tertiary phase when the skin, organs of locomotion, visible mucosa, organs of sense or central nervous system are affected, and for congenital syphilis, notification of change of residence, and notification of patients in hospitals. Notification is imperative even when the patient has applied to the physician for some other ailment. The notification must be in writing on a printed form, free of postage, with details as to whether and where treatment has been applied and whether the patient refuses. Notification is also to be required when treatment is concluded, also on a printed form, specifying whether and when the patient is to be examined or treated again. Notification is also required when the patient stops taking treatment prematurely. An official physician should be deputed to examine those who apply the first time. A special board should have charge of the lists of patients and all the data as to past, present and further treatment. This board should be empowered to warn and compel the patient to submit to treatment, committing him to a hospital for the purpose if necessary. Other members of the family or persons with whom those affected have had sexual intercourse are to be examined and treated, unless injury otherwise is to be feared. The notifying or treating physician can specify when he thinks institutional treatment is necessary on account either of living conditions, carelessness, the profession, refusal to submit to treatment, or the severity of the case. Persons not under the care of any physician can be compelled to submit to examination and to treatment if required. The army and navy authorities should also notify the civil authorities when those requiring treatment pass into civilian conditions. Treatment of venereal diseases by others than registered physicians should be forbidden, as also the sale of means of treatment. Druggists should be allowed to dispense such remedies only on a physician's prescription and only in the prescribed amounts and not repeat. Arrangements should be provided for sufficient treatment for all with venereal disease. The poor should be treated free unless otherwise provided for by the social or life insurance, etc. All physicians, officials and others engaged in the work should be held to strict secrecy in regard to the cases of venereal disease of which they learn in their official capacity. No outsider should be allowed access to the records. Especial care as to secrecy should be maintained in recording the data. The notice, with name, birthplace and birthday and the filled out forms are to be sent to the local board in the patient's birthplace, which is to preserve and record the data.

The report outlines also a set of regulations for the police similar to those in vogue for acute contagious diseases. It specifies that the notification must record the entire name, sex, birthplace and birthday, whether single, married, divorced or widow or widower, the name of the venereal disease, site, kind, stage and previous duration, the time and source of infection, even if only surmised, details as to previous treatment and by whom, with place and date of the notification, and full name and address of the one making it The patient must be informed of the necessity for notification, but told that the data are to be held secret The patient is to be warned against marrying so long as the disease is contagious and, if marriage is contracted, concealing the presence of venereal disease, the marriage can be annulled under certain circumstances and damages claimed

The expense of treatment is to be borne by the patient unless provided for by official, insurance, or charitable appropriations A fine of 90 marks (about $22 50) or a four weeks' prison term are suggested as penalties for failure to comply with the regulations

THE WOCHENSCHRIFT COMMENTS

In the same issue of the *Munchener medizinische Wochenschrift* with the above appears a comment on the way in which questions affecting the future welfare of the race have been forced into prominence by the war It is stated editorially

The full importance of this was realized before the war only by a small number of far-seeing men but the war by revealing the dangers threatening the race from the declining birth rate, has demonstrated to the widest circles the necessity for energetic measures to combat the causes of the decline in the birth rate Associations have been formed at various points to study the questions involved In this same issue of the *Wochenschrift* are reports of the meetings of three organizations of the kind, two of national scope The resolutions voted for the combating of venereal diseases are surprising for those who know with what timidity this problem has been approached in the past Even the National Prevention Society, the Deutsche Gesellschaft zur Bekämpfung der Geschlechtskrankheiten, goes so far as to demand that the venereal diseases be included in the regulations regarding epidemic diseases the *Seuchengesetz* and asks for a limited notification The Munich committee is even more radical in its demands, drawing the ultimate conclusions from the conception of sexual diseases as evils menacing the public health, and hence requiring compulsory notification and compulsory treatment The conclusions formulated by the committee are worthy of all attention not only because they are clear and logical and have been worked up equally well from the medical and the juristic sides, but because they represent a courageous act thus to break decisively with old traditions For reserves and attacks will soon follow, and not the least, we fear, will come from the ranks of physicians Even the comments that have been heard already on the 'consulting dispensaries' for venereal diseases that have been organized throughout the country by the insurance societies the Landesversicherungsanstalten, show that in medical circles any infringement on the principle of medical secrecy is felt deeply The official organ of the Medical Chambers, the *Aerztliches Vereinsblatt* has already declared that the suggestion of compulsory notification of venereal diseases would be the most momentous legislative aberration that it is possible to conceive (*verhangnisvollste gesetzgeberische Verirrung*) The still more far-reaching conclusions of the Munich committee will arouse a storm of protests And yet there can be no doubt that finally the medical profession will acquiesce in some restriction of the conception of medical secrecy in the matter of venereal diseases as has long been the rule with certain contagious diseases The principle of compulsory notification and compulsory treatment has proved its usefulness with other contagious disease It is impossible to understand why for the sexual diseases alone we should renounce this principle just on account of tender solicitude for the false shame of those affected The sexual diseases are among the worst scourges of humanity It is our imperious duty to restrict their devastating action on the strength of the nation (*Volkskraft*) Compulsory notification and compulsory treatment are the only measures which promise effectual results, so they must be introduced even trampling down deep-rooted and otherwise justified ethical considerations The supreme law which has facilitated so many decisions in the course of the war must prevail here also *Salus rei publicae* 'health is a public matter'"

Medicolegal

Liability Where Two Physicians are Employed—Minimizing Damages

(Stokes vs Long (Mont), 159 Pac R 28)

The Supreme Court of Montana affirms a judgment in favor of the plaintiff for alleged malpractice in the reduction and treatment of a broken leg The court says that the plaintiff sent his wife to engage the defendant's services, and the defendant told her that he would need assistance, suggesting that he secure the services of a Dr Wallin, to which she agreed There was much conflict in the evidence as to the course of treatment pursued According to the plaintiff, his wife, and other lay witnesses, the leg was inclosed in a plaster cast without any opening A weight of 4¾ pounds was attached to the foot by means of a cord held by strips of surgeon's plaster adhering to the leg No means were employed such as the elevation of the foot of the bed, to prevent the body from slipping down in the bed, as it yielded to the pull of the weight No examinations were made by means of the Roentgen-ray process, nor were the usual necessary superficial measurements made from day to day No examination could be made by manipulation because the cast prevented The court thinks the evidence made a prima facie case for the jury as to whether ordinary care and skill had been exercised in selecting the means employed to produce a proper union On the other hand, if the testimony of the defendant and Dr Wallin were to be accepted as true, the plaintiff had no case, for, as detailed by them, the course pursued was in every particular beyond criticism Yet, even so the evidence as a whole presented a question as to whether, in view of the result, their testimony was true, and this question was exclusively for the jury

It was contended, furthermore, that Dr Wallin reduced the fracture and chose the mechanical appliances which were used that the defendant only administered the anesthetic, and five days later left for Florida, without having taken any part in the treatment of the injury In other words, the contention was that, since the defendant was authorized by the plaintiff to employ Dr Wallin, and he performed the operation of reduction and thereafter treated the plaintiff exclusively, Dr Wallin's employment constituted an independent contract under which he became solely responsible to the plaintiff If the evidence were in the condition which counsel asserted, their conclusion would undoubtedly be correct If one physician, on leaving temporarily the community in which he is engaged in practice, recommends to his patients the employment, in case of need, of some other physician who is not in any sense in his employment or associated with him as a copartner, he is not liable for injuries resulting from negligence or want of skill in the latter, in case he is employed In such case the employment of the latter is under an independent contract, and he is solely responsible for the result It is held also that when two physicians are employed in the same case and by agreement divide the service as their best judgment may dictate, they are considered as independent agents, each being responsible for his own negligence and no more If, however, one observes and lets go on without objection wrongful acts and omissions by the other, or if the circumstances are such that he ought to have observed such wrongful acts or omissions, he is liable Each is bound to bring to the case the ordinary knowledge and skill of the profession, and also to give his best personal attention and care If one is guilty of want of ordinary professional care and skill in choosing the mode of treatment adopted, and the other expressly or impliedly gives his approval, there is no reason apparent why the latter should not be held guilty also, for by his acquiescence he fails to give the care and attention his employment requires However, the court thinks the evidence in this case did not justify the position of counsel, but justified the conclusion that the defendant considered the case his own until he left, and that both physicians were to be deemed responsible for the result, there being evidence that the treatment was vicious from the start, as "Buck's extension" or other adequate appliance was not used

In order to minimize the injurious consequences of a bodily injury suffered through the fault of another, one is not necessarily bound to submit to a major surgical operation which may or may not result in a betterment of his condition, but, if he chooses to do so he may show what would be the cost of an operation which would minimize the suffering due to his condition at the time of the trial, though he cannot recover for both future pain and the cost of obtaining relief from it

Contract of Hospital to Care for Infant Received Along With Mother

(Roche v St Johns Riverside Hospital (N Y) 160 N Y Supp 401)

The Supreme Court of New York, Special Term Westchester County, holds that it is within the power of a hospital to contract to receive an infant along with its mother and to exercise over it careful supervision and watchfulness in order that it may not suffer harm while the mother is undergoing a course of treatment and that an action may be maintained by the administrator of the estate of the infant when its death is caused by a breach of such contract as when its head is permitted to come into contact with a steam pipe and to remain so long that its death is caused by the burn The court thinks that it has authority for holding this to be true even if the hospital be a charitable institution

Transplantation of the Ureter Following Traumatism and Resection of the Bladder for Cancer

Dr E Starr Judd, Rochester Minn The indications for ureterocystostomy are threefold (1) injury to the ureter during hysterectomy usually for an advanced carcinoma of the cervix, (2) traumatism of the ureter during difficult instrumental labors and (3) resection of the bladder for cancer located about the ureteral orifice Intravesical transplantation of the ureter can be performed and the function of the kidney maintained It is entirely feasible and altogether the procedure of choice in cases of ureteral fistula, and is much to be preferred to sacrificing the kidney

DISCUSSION ON PAPERS OF DRS JACKSON HUNNER AND JUDD

Dr R C Coffey, Portland Ore In 1910 I reported some experimental work on implantation of the ureter by running the ureter along the mucous membrane three-quarters inch before it enters the bladder I have since that time implanted four ureters into human beings, one a double implantation In one the ureter at the time was implanted for exstrophy of the bladder, the operation having been done two years ago That patient was in perfect health There is no evidence of ascending infection I have had two cases of cancer of the bladder, one patient went along for eight months with the ureter functionating perfectly, but I have not heard from this patient for over a year

Dr J Wesley Bovée, Washington, D C Implantation of the ureter into the bladder for injuries is an operation which should be avoided It is one in which we must expect as a rule, bad results The bad results, when we have immediate success in the operation, are almost exclusively due to constriction at the point of junction or to too large an opening We get a backing up of urine in the ureter and in the pelvis of the kidney which sooner or later does away with the function of the kidney, if we have a stricture at the point of junction

Dr Robert L Payne, Norfolk, Va In 1907 I carried out some experimental work in uretero-ureteral anastomosis There is no structure in the body which heals more kindly and lends itself so well to surgical intervention as the ureter if it is handled properly The success of surgical procedures on the ureter depends on the blood supply The ureter must be handled with extreme gentleness in order not to compress or injure it and set up thrombosis of its periureteral blood supply

Dr Howard A Kelly Baltimore Many mild infections are liable to result in stricture of the ureter My work has been confined very largely to strictures of the ureter of major caliber, and they are tighter I have some of these cases on hand now that are interesting I remember my first case in 1888 I diagnosed a tight stricture of the ureter and treated the patient for some time We were not recognizing tuberculosis then as readily as we are today, and it was a case of tuberculosis In 1891 I took out the kidney doing a nephro-ureterectomy The patient died at the end of one week My next case was one of gonorrheal stricture of the right ureter I dilated this stricture, and the woman got well and is living today

Dr Charles R Robins Richmond, Va In the first case that came under my observation the patient had a bleeding uterus due to fibroids She gave a history of having had the left kidney removed about ten years previously On account of the fact that she had only one kidney left, we made an elaborate examination and were not able to detect any trouble with the right kidney Hysterectomy was performed without any untoward result except that as the patient was convalescing from the operation she developed a high degree of pyelitis in the right kidney As there was only one kidney to deal with it gave me considerable concern This was treated by lavage of the kidney, and after a rather slow convalescence lasting for a long time, she finally made a recovery sufficient to go home Her fever which was high and subject to extreme exacerbations, had gone down to normal, and she was allowed to go home, although there was still some pus in the kidney Lavage was practiced at regular intervals and we were unable to discover anything which would suggest that the patient had a stricture of the ureter

Dr George Tully Vaughan Washington, D C I have seen two or three cases one in a man aged 24, who had trouble in his right side of a chronic character off and on for a considerable time Cystoscopy revealed no urine coming from the right ureter He was operated on because of appendicitis The appendix was found much inflamed, and inflammatory tissue surrounded the ureter The ureter above this point was dilated below it was very small The appendix was removed, the tissue dissected off, and the urine passed down through the constricted part of the ureter into the bladder I operated on this patient about six months ago, he continued to pass urine from that side, but after six months there has been a subsidence

Syphilis of the Stomach

Dr William A Downes, New York Observations have been made in eight cases of syphilis of the stomach for periods extending from one and one-half to three and one half years Two cases were of the congenital type, and six of the acquired One patient died of a generalized syphilis one and one-half years after the diagnosis was made The remaining seven are well from a clinical standpoint, so far as their stomach symptoms are concerned They are able to follow their usual vocations and have gained from 10 to over 50 pounds in weight Five of the patients were subjected to gastro enterostomy for the relief of symptoms due to obstruction

Congenital Lipoma of the Cheek

Dr Joseph Ransohoff, Cincinnati The first patient was a child of several months with a large myxolipoma of the cheek The second case, also congenital is of the cheek The child was operated on when 1 year of age The second operation revealed the fact that in conjunction with the lipoma there was very extensive lymphangioma In many of these congenital lipomas, the lymphangiectasis is a common complication

Traumatic Asphyxia

Dr J Garland Sherrill, Louisville, Ky A bridge builder, aged 35 was caught and squeezed, he was doubled up and his head brought down on his knees by at least 7 tons of metal He presented marked ecchymosis and swelling over the head and forehead and down to the malar bones This area was dark purple and clearly delineated by an abrupt margin where the healthy color of the skin joined the swollen discolored part Pressure did not affect the discoloration There was present a subconjunctival hemorrhage on each side which was bright red contrasting strongly with the purplish discoloration of the adjacent tissues—a striking appearance Rupture of each eardrum with hemorrhage from the ear canal was noted Bleeding also occurred from the nose There were no other injuries, except a few minor bruises and a fracture of the seventh rib on the right side The patient was fully conscious and the reflexes were normal, with no evidence of cerebral injury The pupils were equal and responsive to light and accommodation The diagnosis of traumatic asphyxia was confirmed by the subsequent history of the case The patient recovered without untoward incident

Zinc Chlorid in Uterine Hemorrhage, Particularly When Caused by Uterine Myomas and Metro-Endometritis

Dr H J Boldt, New York I do not approve of the removal of the uterus for bleeding if it is not the seat of a neoplasm Zinc chlorid is used in all instances of severe bleeding whether due to metro endometritis or simple endometritis, but particularly when caused by interstitial myomas of small size In large tumors, especially of the uterus, it is more desirable to extirpate I use a 50 per cent solution of zinc chlorid more frequently than weaker solutions Care must be taken to avoid having the medicament come in contact with the cervical mucosa lest a stricture result In several instances of very profuse bleeding from interstitial myomas, some measuring about 6 inches in diameter, in women past 40 years of age, I have seen complete amenorrhea established after using twelve, or even a less number of zinc chlorid applications While the tumors do not decrease in size, the health of the patients improves as the result of amenorrhea There must be no oozing of blood from the endometrium when the intra-uterine applications are made, the uterine cavity must be dry If it is not, it may be prepared with an intra-uterine tampon of styptic gauze

Cancer of Mammary Tissue Misplaced in Axilla

Dr J Shelton Horsley, Richmond, Va An unmarried woman, aged 46 who had two sisters with cancer, noticed a growth in the right axilla which became quite painful There was no evidence of any primary lesion elsewhere An examination of removed tissue showed it to be malignant Three years and four months after the operation, the patient was entirely free from recurrence

---

Prosecution of Quacks and "Patent Medicine" Fakers—A recent *Bulletin* of the New York City Department of Health gives a list of the prosecutions made by the department under that section of the Sanitary Code regulating the manufacture or sale of drugs or medicines which are adulterated or misbranded Most of the cases prosecuted thus far have been by inspectors of the Bureau of Food and Drugs During the past three months Anthony Ofries has been fined $100 for selling phenacetin which was adulterated, Charles Stiriz was given thirty days for selling a paralysis "cure", Smith and Zibriskie were fined $800 for selling an infantile paralysis 'cure' Salvatore F Sellare for the use of wood alcohol, $500 and thirty days, J A Miller for adulterating phenacetin and other tablets, $500, and Peter U Russ for selling a consumption 'cure" $100 or thirty days A number of additional cases are now waiting trial

7 Factor of Inanition in Development of Acetonuria in Children B S Veeder and M R Johnston St Louis —p 89
8 *Infantile Scurvy Therapeutic Value of Yeast and of Wheat Embryo A F Hess New York —p 98

1 Congenital Familial Cyanosis—The results of the analyses made by Hess and Pearce show that the cyanosis is not a faulty gas exchange of the blood as it passes through the lungs for this is above normal, but rather lies in a reduction of the amount of blood which reaches the left ventricle from the pulmonary circulation The rate of blood flow is normal or above normal through the systemic circulation They believe therefore, that the blood sent from the left ventricle is a mixture of venous and arterial blood, and that the tension of oxygen in the arterial blood is below that normally found The larger percentage of reduced hemoglobin in the arterial blood than is found in normal individuals imparts the blue color to the skin The amount of oxygen, however, delivered to the tissues is sufficient to meet their needs, due at least in part to the increased hemoglobin content of the blood, and the amount of carbon dioxid excreted by the lungs is kept within normal limits by the greater difference in the effectual diffusion pressure of carbon dioxid between arterial and venous blood in the lungs

The cyanotic boys are not different from other boys in their ability to do the ordinary things of life However, their power of endurance does not compare with that of a normal boy When forced pulmonary ventilation is pushed, the color markedly improves These boys are all subject to bronchitis and this tendency might be explained on the assumption that a deficient oxygen supply in the blood of the bronchial artery is a factor in producing congestion or edema in the lungs The authors conclude that the pathology consists of a cardiac abnormality The methods, outlined, afford a new means of investigating the relationship of the pulmonic circulation to the systemic circulation, and in the present case renders the diagnosis of a septal or ductus defect highly probable

2 Phenol Excretion in Urine of Infants—In the series of fifteen infants examined by Moore the phenol excretion per kilogram of body weight is less in the breast-fed than in the artificially fed infant In infants and in adults there is an interrelation between the total phenol excretion and the protein intake as measured by the total nitrogen excreted in the urine This relation can be expressed in the general term, trebling the protein intake doubles the phenol excretion Contrary to the earlier findings phenol is quantitatively present in the urine of every new-born infant, the average of these nineteen cases being 11 2 mg for the first three days of life As phenol is present during this period of starvation, it must originate in part through endogenous metabolism

3 Chemistry of Spinal Fluid of Children—Chemical examination of the spinal fluid in ten normal cases in children gave the following results The total nonprotein nitrogen varied between 17 and 26 mg per 100 c c of fluid, the urea nitrogen varied between 7 and 13 5 mg , the creatinin varied between 0 7 and 1 5 mg In no case was there enough uric acid present in the spinal fluid to give a positive quantitative test The sugar content varied within very narrow limits (0 07 and 0 1 per cent) The concentration of total nonprotein nitrogen in the spinal fluid averaged 75 per cent of that in the blood, the urea 82 per cent of that in the blood and the creatinin 60 per cent of that in the blood The chemical examination of the spinal fluids from diseased children showed the following conditions In chorea, idiocy, syphilis, epilepsy and enuresis the nonprotein nitrogenous constituents of the spinal fluid closely paralleled the normal

In acute nephritis without uremic symptoms the total nonprotein nitrogen was slightly increased and uric acid was *present in small amounts* In acute nephritis with uremic symptoms the total nonprotein nitrogen, urea and creatinin were markedly increased and uric acid was present in slight amounts The sugar content was also increased In serous meningitis the nonprotein nitrogenous constituents, as well as the sugar content were within normal limits In tuberculous meningitis the total nonprotein nitrogen and the urea were normal, but the creatinin was slightly increased Uric acid was present in every case, but the sugar content was normal or slightly reduced In cerebrospinal meningitis the nonprotein nitrogenous constituents were normal, but the sugar content was reduced In a fatal case of meningitis in which the streptococcus was found, the nonprotein nitrogenous constituents were normal and sugar was absent In the early stages of infantile paralysis the nonprotein nitrogenous constituents, as well as the sugar content, were within normal limits

6 **Sodium Chlorid Excretion**—The authors' metabolism studies support the clinical conclusions as to the beneficial effects of repeated saline injections

8 **Yeast and Wheat Embryo Infantile Scurvy**—Clinical experience demonstrated that yeast is of no value in scurvy either as a prophylactic or as a curative dietetic agent It was found, however to possess virtue as a stimulant to growth, when added to the milk in the form of the fluid autolyzed yeast or given to older infants as a desiccated powder The embryo or germ of the wheat seed manifested some value as an antiscorbutic, but not sufficient to render it useful in this connection from a practical or clinical standpoint The watery extract, which is readily prepared, was found to stimulate growth and may be used to advantage, on account of this quality as a substitute for barley in milk preparations

20 Aspirating Bougie for Esophagus and Stomach M Einhorn New York—p 106
21 *Treatment of Circulatory Failure in Acute Infections. M Goodridge New York—p 107

12 **Glucose-Nitrogen Ratio in Diabetes Mellitus**—By means of improved experimental methods it was established by Janney that the fasting urinary glucose-nitrogen ratio of severe diabetes mellitus is about 3 4 1 The glucose-nitrogen ratio is, therefore, to be regarded as a definite index of the severity of this disease In association with other factors to be considered, the glucose-nitrogen ratio is a valuable prognostic sign

13 **Starvation Treatment of Diabetes**—Two important points are worthy of note in the authors' observations 1 The ferric chlorid reaction is sometimes absent when acidosis is present, and is less sensitive, too, than the nitroprussid reaction 2 The urine does not always show a reaction for acidosis even when the blood gives a positive quantitative result, therefore, the excretion of the acid bodies is not necessarily an index of the degree of acidosis, while in diabetes the reverse occurs Sometimes, however, in Martin and Mason's cases, acidosis was initiated by the starvation, at other times a preexisting acidosis was increased, though usually it disappeared Evidently there is a variation due to many circumstances, though starvation ultimately does make the urine acid free In one persistent case of very mild diabetes, with prolonged mild acidosis, interrupted periods of a fat free diet seemed especially useful in clearing up remnants of the acidosis In one very severe case in which the acidosis disappeared on starvation, it developed again on a protein-fat diet, and later on disappeared with one day of starvation Sodium bicarbonate was given (32 gm per diem) for five days, with resulting elimination of more ketone bodies Excretion of these bodies ceased again with cessation of bicarbonate administration Another experience worthy of note is the varying ratio of the acetone bodies to beta-oxybutyric acid Sometimes there is much acetone and little beta oxybutyric acid and sometimes the reverse occurs There seems to be little constancy, and the percentage of 60 to 80 as usually recorded, is subject to many wide exceptions

14 **Hyperglycemia in Diabetes**—The study made by Epstein and Felsen showed that the withdrawal of food from certain cases of diabetes provokes, or aggravates the acidosis The acidosis causes an increase in the blood sugar content, in one of two ways (*a*) by augmenting the mobilization of sugar, and (*b*) by affecting the sugar secreting function of the kidneys Liberal, but judicious, administration of carbohydrate may control the acidosis provoked by the withdrawal of carbohydrates or complete fasting, thus leading to a general amelioration of the diabetes A progressive rise in the blood sugar content associated with a gradual fall in the alveolar carbon dioxid is indicative of impending coma

15 **Fatal Case of Diabetes Mellitus**—A case of fatal diabetes with large cell hyperplasia of the spleen, lymph nodes and liver is presentd by Williams and Dresbach It is the fourth case on record so far as the authors can tell The hyperplasia has some resemblance to the cell changes in Gaucher's disease of the spleen It is shown that overfeeding with fat increases acidosis in diabetes and probably bears some relation, as yet not understood, to lipoidemia The acidosis is readily controlled A brief discussion of some of the newer ideas regarding fat metabolism is given

18 **Toxemias of Pregnancy**—Losee and Van Slyke found that neither blood nor urine of eclamptic women shows, as a rule, an amino acid content above normal limits Inspection of the other nitrogen figures of the urine shows that the urea in eclampsia is usually below the average normal, often strikingly so, even if calculated on the basis of total nitrogen of the urine minus the albumin nitrogen The only eclamptic urines which showed more than 70 per cent of urea nitrogen were those obtained one or more days postpartum The ammonia was often higher than the average in normal individuals but the abnormality is less striking than that of the urea All the cases of pernicious vomiting showed strikingly high ammonia percentages, none of the cases showed less than 16 9 per cent In five cases of nontoxic pregnancy the nitrogen ratios were normal The authors conclude that the toxemias of pregnancy can be attributed neither to failure in diaminization of the amino-acids, nor to the moderate degree of acidosis observed The nature of the toxin or toxins remains unknown

21 **Circulatory Failure in Acute Infections**—In Goodridge's opinion there is neither clinical nor experimental evidence to support the belief that failure of the vasomotor center is the cause of the symptoms of circulatory failure which occur in acute infectious disease While it has been shown experi-

mentally that the heart is not exhausted in animals dying of acute infectious diseases, there is no positive proof that the myocardium is wholly efficient in its effect to maintain the circulation in the body of the living animal under such circumstances The hypothesis which suggests the existence of a third center controlling the flow of blood is important even though it is not yet proved Alcohol and strychnin are absolutely worthless drugs in the treatment of circulatory failure Epinephrin and pituitary extract are useful in the treatment of sudden circulatory collapse, but their action is not a sustained one The nitrites are valuable additions to the therapeutic armamentarium in the treatment of pulmonary edema under certain circumstances, because of their selective action in constricting the pulmonary arteries Caffein increases the flow of blood when the supply to the heart is "inadequate" probably by an action on some mechanism outside of the heart One of the most important contributions of recent times on the action of digitalis is the proof electrocardiographically that it exerts precisely the same effect on the heart in febrile conditions that it exercises in nonfebrile states, and whether the rhythm is initiated in the normal pacemaker or not

27 Care and Asepsis in Hospitals for Infants A Strauch Chicago —p 899
28 *Heart Disease in Infancy and Childhood A L Goodman New York —p 909

28 **Heart Disease in Infancy and Childhood**—Cases of rheumatism in children are treated by Goodman in the following manner During an acute attack give the patient sodium salicylate, if this is not well borne by the mouth use it per rectum If there is already an accompanying heart condition, use fluidextract of digitalis and spartein sulphate in rather large doses If there is no accompanying heart complication, give smaller doses and examine the heart at frequent intervals to observe any occasion for increasing the dose The children are kept in bed until all vestige of pain has disappeared, and the heart sounds have improved or become normal The children's guardians are then warned of the so-called 'growing pains,' and the moment the pains reappear, or difficulty in walking is noticed by the parents, the children are at once placed in bed and the salicylate given every hour or two until the pain has disappeared Give the salicylate, after an attack, two or three times a day for two weeks longer Children with rheumatism should not be subjected to extremes in temperature Rapid evaporation from the surface of the body should be avoided In summer light cotton underwear should be used, and in winter a mixture of wool and cotton will be found more serviceable as it is not so heavy as the wool alone, and, absorbs perspiration more readily than the allwool garment

The children should receive daily lukewarm baths never hot and never cold, followed by a brisk rubbing with a coarse bath towel If there exists any adenoid growth or enlarged tonsils they should be removed When the children come in from the street after play their stockings should be removed, their feet rubbed dry and a fresh pair of stockings substituted Damp dwellings should be avoided Parents with children subject to rheumatism should be told that they may not live on the ground floor The sleeping room should be sunny and have a southern exposure, if possible. In reference to diet Beef should be avoided, especially beef juices or extracts, spiced and fried foods should not be permitted Sweets, such as candy and pastry, should be forbidden, and, above all, coffee, tea and alcohol

36 **Goodman's "Autoserum" Treatment of Chorea**—Goodman's method consists in the injection one to four times repeated of the patient's own serum into the subdural space of the spinal canal Faber says that improvement, shown by the disappearance of choreic movements occurs frequently within three days or even less, and a majority of cases remain permanently free of movements Certain instances of recurrence are mild and readily amenable to the action of another injection Of the thirty cases treated by Goodman fourteen received one injection eight received two injections, five received three injections, and three received four injections Of those receiving one injection, twelve were cured and two markedly improved Of those receiving two injections, five were cured and three markedly improved Of those receiving three injections, two were cured and one markedly improved one slightly improved and one unimproved Of those receiving four injections, one was cured one markedly improved and one unimproved Faber used the method in three cases An almost immediate cessation of choreic movements followed a single injection of the patient's own serum into the spinal canal, and no recurrence of symptoms has occurred in a little over a month

64 **Antigenic Properties of Different Strains of Bacillus Typhosus**—By means of the alexin fixation reaction Hooker was able to demonstrate consistent antigenic differences among some strains of *B typhosus* By means of agglutinin absorption experiments, findings have been obtained that, in general, harmonize strikingly with the results of cross fixation This confirmatory evidence, secured by a widely different serologic method, Hooker says, tends strongly to prove that these antigenic differences among typhoid strains as demonstrated by alexin fixation, represent an actual condition and are not fortuitous The facts that a serum immune to any recently isolated strain cross fixes with all other strains old or young while serums immune to older strains do not so cross fix, would lead to the seemingly justified assumption that only do the young strains contain all of the antigenic complexes of typhoid bacillary protein The logical conclusion, then would be that a young strain ought to afford the most efficient protection when used for prophylactic immunization against typhoid However, the results of the work on agglutinin absorption, if correctly interpreted, do not warrant the assumption that a univalent vaccine is sufficient Therefore it seems advisable, for the present, to recommend the use of a balanced polyvalent typhoid vaccine, for immunizing and therapeutic purposes

65 **Hecht Complement Fixation Reaction**—The Hecht reaction as modified by Gradwohl, and conducted with a properly standardized antigen Kolmer claims constitutes a very delicate control over the Wassermann reaction, although it possesses a greater negative than a positive value The fewest pseudoreactions occurred with an extract of acetone insoluble lipoids An alcoholic extract of syphilitic liver proved of least antigenic sensitiveness and yielded the highest percentage of false or pseudoreactions The modified Hecht and Wassermann reactions including the use of cholesterinized extracts, yielded similar results in 82 per cent of a series of 360 serums The modified Hecht reaction yielded about 16 per cent more positive reactions and about 12 per cent more true positive reactions than the Wassermann reaction conducted with a cholesterinized extract as antigen, 26 per cent more true positive reactions than the Wassermann conducted with an alcoholic extract of liver and 18 per cent more true reactions than the Wassermann with an extract of acetone insoluble lipoids Kolmer believes that the modified Hecht reaction has its greatest value as a serologic control in the treatment of syphilis

66 **Methods of Performing "Daily Titrations" for Wassermann Reaction**—Ottenberg's experiments demonstrate that in the Wassermann reaction compensating for increased hemolytic strength of the complement by using a diminished amboceptor dose inevitably leads to a negative result in certain grades of weakly positive serums The correct method of compensating for complements of greater than average hemolytic strength is by using a smaller dose of complement The method of doing daily complement titrations is greatly to be preferred to the method of keeping the dose of complement fixed and doing daily amboceptor titrations

68 **Postmortem Wassermann Reactions**—In 90 4 per cent of cases showing postmortem anatomic lesions of syphilis or presenting positive evidence of syphilis in their histories the serums postmortem gave positive Wassermann reactions Only 7 per cent of 282 cases showed negative reactions in the presence of anatomic lesions (aneurysms) characteristic of syphilis

69 **Von Dungern's Indigo Test for Syphilis**—Flood claims that the alkali and not the indigo is the sole inhibiting agent in the von Dungern's test The method is of no value in the serum diagnosis of syphilis for in a series of 140 serums forty of which were evidently syphilitic, coagulation occurred in but three with the prescribed amount of reagent

70 **Wassermann Test for Syphilis**—The use of a simple alcoholic antigen with the first incubation carried out in the ice-box for four to twenty-four hours was found to be more sensitive in the detection of syphilis than the other procedures tested

72 **Anaphylatoxin Theory of Anaphylaxis**—Characteristic anaphylactic symptoms were produced by Weil exceptionally by the simultaneous but separate injection of antigen and antibody intravenously They may be produced by the simultaneous separate injection of two foreign serums or proteins not related as antigen and antibody

111 *Toxic Effect of Emetin Hydrochlorid H H Johnson and J A Murphy U S Army—p 58

111 **Toxic Effect of Emetin Hydrochlorid**—Emetin hydrochlorid has been used by Johnson and Murphy as the principal remedy in the treatment of 142 cases of endamebic dysentery The authors have found its use, results and dangers somewhat analogous to those of salvarsan in syphilis Two men died under treatment from peculiar and unusual conditions in no way connected with the disease from which they suffered, five other cases showed physical signs and symptoms which it is believed were due to emetin In the two fatal cases there was (1) inability to swallow after food had reached the esophagus (2) hepatization of the lungs and (3) rapid and uncontrolled action of the heart Both patients showed, at first, a general motor weakness affecting particularly the muscles of the back of the neck with a tendency for the head to fall forward later a difficulty in swallowing, and finally a pneumonia of lobar type. One case showed decided cardiac signs, possibly attributable to failure of vagus control These cases were treated with emetin, particularly during the acute stage of the disease, and received in all 23½ and 25 grains each In the five cases mentioned the untoward symptoms were somewhat similar and disappeared promptly when medication was stopped

The authors present method of administering emetin in cases of endamebic dysentery is as follows ⅓ grain daily, increasing ⅓ grain per day until 1 grain is given, continued until 8 grains have been given With the emetin, bismuth subnitras in large doses, is given For the succeeding period of ten days colonic irrigations of 1 1,000 quinin solution are given once or twice daily If the stool is still positive a subsequent course of emetin, 1 grain daily, is given for three days By this method of treatment the patient receives 11 grains, which is less than the single lethal dose stated by Sir Leonard Rodgers This procedure usually suffices to free the stool from ameba and cysts There are occasional cases which will require a third course which is not instituted until after a sufficient lapse of time and not then if asthenia or special contraindications exist, that is, motor weakness, irregular heart action, nervous exhaustion or irritative diarrhea In view of the experiences the authors advise a very careful and watchful course in the use of emetin, in protracted cases especially

119 **Bacterial Cultures of Human Spleens Removed by Surgical Operation**—Bacterial cultures were made by Sellards of human spleens removed for surgical purposes in ten cases The cultures from four of these spleens remained sterile In three instances a micrococcus was obtained and in three other cases an anaerobic bacillus developed The anaerobic bacillus in its morphology, in its cultural characteristics and in its serologic reactions resembled very closely the bacillus isolated by Plotz in typhus The weight of evidence indicates that this group of organisms represents parasitic but nonpathogenic flora of the human body There is not sufficient evidence to ascribe a specific etiologic role to members of this group of anaerobic bacilli in either typhus or in pernicious anemia

5 **Influence of Antiseptics on Leukocytes** —If it be true that some part (how large a part is at present unknown) of the spread of infection in wounds is due to a breakdown in the defensive mechanism of phagocytosis, of which return immigration is only one phase, if, in other words, a certain number of pus cells in infected wounds reenter the circulation or the tissues carrying ingested but still living organisms with them, and if a certain proportion of the latent infection in sinus cases and the recrudescent sepsis which breaks out in healed wounds is due to this same cause then, says Bond, any method of wound treatment to be successful must deal with the problem of the return immigration of germ laden phagocytes If antiseptic solutions when applied to wounds are sufficiently strong to kill the phagocytes and their cargoes and so prevent their reentrance into the tissues they will also inhibit emigration and phagocytosis The irrigation of a wound with normal saline favors emigration and ingestion but it does not prevent return immigration The application of hypertonic saline on the other hand, may prevent return immigration by killing the leukocytes, but it also checks emigration and phagocytosis

Bond's observations suggest that return immigration of leukocytes is intimately associated with the spread of infection and recrudescent sepsis in wounds The spread of infection is due to a breakdown in one or more of the factors on which phagocytosis depends Either the wandering phagocytes do not emigrate into the invaded area in sufficient numbers, or, having emigrated they do not ingest the organisms, or the breakdown of the defensive mechanism may occur at a later stage The phagocytes may emigrate and successfully intern the invading organisms, but they may fail to digest them or things may go wrong during return immigration The organisms may be liberated by the leukocytes while still alive, just as the pigment granules may be liberated, and they may retain sufficient virulence to originate a recrudescent infection in a new area It is quite likely, says Bond that some part of the autointoxication which attends the too free movement of infected limbs may depend on a liberation of ingested organisms brought about by injury to germ containing leukocytes rather than to a mechanical pumping of the organisms or their toxins into the tissues

11 Outdoor Occupations for Tuberculous Cases J W Allan —p 321
12 *Advanced Pulmonary Tuberculosis W T G Davidson —p 330
13 Liver Abscess Among Soldiers A C Faulds —p 337

12 **Tuberculin in Treatment of Advanced Tuberculosis** —Davidson's experience has been that tuberculin has done good even in cases of fairly advanced phthisis, though the number of cases treated has not been sufficient to make the evidence conclusive He does not claim to have cured any patient of the disease with it, but he has treated about fifty patients, specially selected, but all with advanced lesions These patients put on weight, their general health improved, immunity was brought about from toxemic symptoms, cough became very slight and the sputum scanty, and in some cases both entirely disappeared The lesion in the lungs was not so marked, in several cases the local signs had practically disappeared, and the patients were dismissed very much improved

New tuberculin B E was found to give the most satisfactory results The initial dose was 0 3 c c of a dilution of one in a million, and a dose was administered biweekly unless there was some contraindication each subsequent dose being increased by 0 3 c c Whenever the dose exceeded 1 c c a dilution of the fluid ten times less (one in 100,000) was used For example, the first four doses would be 0 3 c c, 0 6 c c 0 9 c c of a dilution of one in a million, the next dose instead of being 1 2 c c of the same dilution would be 0 2 c c of a dilution of one in 100 000, and so on, until the undiluted tuberculin was given, when the increase of the dose each time was 0 1 c c The treatment lasted for about three months and came to a conclusion after 1 c c of pure tuberculin was given But it is evident that the treatment should be kept up for a longer period, since many cases which had improved under its influence, and had kept well for some time afterward, tended to get worse again when away from the influence of the tuberculin

19 Two Fatal Cases of Metastatic Gas Gangrene K Taylor —p 1057

14 **Antiseptic Treatment of Wounds** —The antiseptic advocated by Feldman and Walton is prepared by rubbing together in a mortar crystals of pure phenol and camphor in equal parts by weight—a perfectly clean sweet smelling liquid being thus obtained As is the case when using any other application it is primarily essential to provide adequate drainage When seen in a relatively early stage the wound, if deep or punctured should be opened under general anesthesia so as to eliminate, so far as possible, any pockets in the tissues and all foreign bodies, loose pieces of bone, or necrotic tissue should be removed When the wound has been freely opened sufficient of the liquid is poured in to reach the whole surface of the tissues In large wounds as much as 1 or 2 fluidounces may be required although as a general rule one or more fluidrams are sufficient Drainage tubes are inserted as required and packed round with gauze soaked in the fluid. On the surface dry gauze is applied It is only necessary to change the dressing every forty-eight hours, when a few drops of the fluid are poured down the tube and fresh soaked gauze applied to the raw surfaces When the treatment is commenced some days or weeks after the infliction of the wound it is again necessary to open up all sinuses and pockets so that the fluid may reach all the septic areas and if necessary tubes should be inserted so that free drainage is established The fluid is then used in the same manner as previously It is noteworthy that the fluid can be handled freely without doing any harm to the skin, but if left for a prolonged period in contact with patient's skin around the wound a certain amount of burning may be caused, for this reason surface dressings should be formed of dry gauze It is rarely necessary to smear the surrounding skin with sterilized petrolatum

It is claimed for the method that it overcomes sepsis more rapidly than other methods With its use amputations are much less frequent It diminishes pain rather than increases it, as is so often the case with other dressings The dressing requires to be changed only at long intervals Its use is associated with no danger The amount of work in the ward is greatly diminished It is most suitable to the conditions of modern warfare and can be easily applied to cases that have to travel

29 Recovery from Tetanus under Intravenous Serotherapy P Nobecourt and E Peyre—p 588
30 Milk as Vehicle of Infection of Malta Fever J Comby—p 597

27 **Dyspeptic Diarrhea**—Blanc emphasizes that this disturbance is the result of a disproportion between the food that has to be digested and the juices which are to digest them Consequently each of these factors must be investigated separately The food may be at fault or one or more of the digestive juices may be inadequate The clinical picture is described in detail of nervous functional and dyspeptic diarrheas and the means of investigation in each, especially when the diarrhea is due to insufficiency on the part of the pancreas Emaciation is an important sign of the latter and also anemia, as the pancreas secretes hemolysins when it is becoming atrophied There is liable also to be hint of bronzing, and colic on the left side is a characteristic feature The stools are whitish and oily, the palmitin coagulates *en masse* like tallow There is also much residue of undigested meat fibers Steatorrhea and creatorrhea may occur in normal conditions when fat and meats are eaten in undue amounts

Among the useful tests are alimentary glycosuria, and alimentary steatorrhea and creatorrhea If the pancreas functioning is defective, Blanc advises to restrict the intake of meat and of fats increasing the proportion of starch, which is digested well in such cases, and stimulating secretion in the pancreas by giving hydrochloric acid and pepsin, which aid in the formation of trypsin To stimulate production of steapsin he gives pills of bile between meals, as the biliary acids stimulate secretion of steapsin Intestinal diarrhea from fermentations does not affect the general health as a rule, but neurasthenia is common The stools reveal the acid dyspepsia The fermentation irritates the bowels and they protect themselves by mucous secretions The diet should be modified into an antidiabetic diet, meat, cream, fat, butter rice and potatoes Casein may be given and the bowels disinfected

28 **Meningeal Reactions in Syphilitics**—Lavergne has had four cases of meningeal symptoms in children for which neither tuberculous nor cerebrospinal meningitis was responsible In two they were a manifestation of inherited syphilis in the others the meningeal reaction occurred in the course of an acute infectious disease All the children recovered completely None of them had ever presented signs or symptoms otherwise that might have suggested an inherited taint, but the Wassermann reaction was found positive and under mercurial treatment recovery was soon complete Whenever meningeal reactions are accompanied by an appreciable lymphocytosis, the Wassermann test should be applied without delay

38 Suture of Wound in Heart (Plaie du cœur traitee par la suture, avec survie de neuf heures, chez un blesse atteint de plaies multiples) I rtaud—p 541

36 **Antitetanus Serum in Treatment of Tetanus**—Merle has been making extensive experiments which have demonstrated anew the special affinity of the nerve cells for the tetanus toxin, and also that they are able to neutralize a certain proportion of the toxin The toxin arriving in amounts greater than the cells can neutralize is adsorbed by the cells and held so firm by them that it does not feel the influence of any antitoxin injected This seems to be able to act only on the toxin left in the blood stream, but Roux and Borrel, by injecting the antitoxin directly into the brain of guinea-pigs were able to neutralize the toxin already fastened in the nerve cells The application of similar measures in the clinic has not given the anticipated results, probably, Merle says, because the antitoxin has not been applied directly to the cells in sufficient quantities He cites thirty-seven cases reported by various writers of recovery from tetanus under intraspinal injections of large doses of antitetanus serum They encourage further trials of the method, injecting the antiserum into the spinal canal and rectum, intravenously and subcutaneously, to act on the toxin by all methods of approach A transient aggravation of the symptoms may follow

37 **Entero-Anastomosis Without Exposing the Lumen**—The bowel is crushed with clamps on each side of the portion to be resected With small forceps the bowel is seized at the edge of each of the crushed segments The intervening segment and its mesentery are cut out and the two small forceps are brought together and the stumps are sutured together, the stitches including the forceps The forceps are then withdrawn and a grooved sound is introduced in place of the forceps and is worked in until it has spread apart the tissues crushed together by the clamp This is done for each stump, loosening apart the mucosa and muscular walls of the bowel and thus rendering the bowel permeable It is claimed that this method ensures hemostasis while it avoids the operations in two sittings, and the lumen is not opened until the suture is complete Gudin's clinical experience with this method has been extremely favorable He gives illustrations of the various steps of the method for entero-anastomosis, and also an illustrated description of the same principle applied to gastro-enterostomy

40 *Experimental Research on Section and Restoration of Nerves in Dogs E Duroux and A Couvreur—p 572

39 **Hemorrhagic Jaundice**—Martin and Pettit give a complete review of the present status of what they call icterohemorrhagic spirochetosis, including an account of their own research, and clinical experiences, reproducing a typical fever chart, and describing the results of inoculation of guinea-pigs with blood or urine from patients The clinical case reported was a laboratory infection, Dr G L, who has been doing this kind of work for years, having been in charge of the glanders service for ten years He inoculated guinea-pigs at

a two days' interval and six or seven days later developed a severe typhoid-like condition accompanied by intense jaundice The disease reached its height in a week and guinea-pigs inoculated died of spirochetosis in five days Improvement became evident by the twelfth day and he was able to get up the eighteenth day, but he was unable to start to work for three or four months The case shows that the incubation is one week Infection seems to have occurred when the virulence of the virus had been enhanced by the passage through guinea-pigs In the second case the disease was mild but confirmed by inoculation of guinea-pigs Martin and Pettit have produced now from the horse an antiserum which has proved its efficacy conclusively on guinea-pigs, even at the third day of the infection otherwise fatal in six days They say that every infectious jaundice should be examined for the Inada-Ido spirochete, of which they give some illustrations

40 **Operations on Nerves in Dogs**—Dogs seem to stand the severing of even large nerves much better than man But even in dogs the immediate restoration of function is illusory The peripheral end does not recuperate its functions until it has been penetrated by the fibers from the central stump Suture and possibly grafting give best results Compression from proliferation of connective tissue must of course always be corrected

Correspondenz-Blatt für Schweizer Aerzte, Basel

December 16 1916 XLVI No 51 pp 1697 1728

41 *Welfare Work for School Children with Ear Disease (Fürsorgebestrebungen fur ohrenkranke Schulkinder) O Laubi —p 1697

42 Utilizing the Muscular Force in Stump of the Arm to Control Functioning of Artificial Hand (Un nouvel appareil pour les mouvements volontaires de la main artificielle) N Fialko —p 1703

43 *Regular Daily and Yearly Fluctuations in the Body Temperature (Bemerkungen uber die regelmassigen taglichen und jahrlichen Schwankungen der Körperwarme und ihre Herkunft) R Ammann —p 1710

41 **Welfare Work for Children with Ear Disease**—Laubi states that for twenty-two years he has examined the ears of the children entering school for the first time at Zurich As the child's aptitude for profiting by the school instruction depends on the functioning of the eye and ear, it is to be deplored that examination of the eye and ear is not the rule everywhere on entering school At Zurich, the school inspector or teacher examines the children first and all who cannot hear the whispered voice at 8 meters are referred to an ear specialist During the twenty-one years, 1894-1914, from 4 8 to 21 6 per cent were thus found abnormal, a total of 6,785 out of 62 738 children examined in these years, namely, 11 8 per cent of all the boys and 9 8 per cent of the girls (Nager found 40 per cent at Lucerne, and Bezold has reported 25 8 per cent, Ostmann 28 4 per cent, and Denker 23 3 per cent, who were unable to hear a whisper at 8 meters) A circular is sent the parents giving the location and hours of the policlinic where ears are treated, and the children are obliged to bring a certificate to the effect that they have applied for treatment

The very deaf are given a desk near the teacher, the best ear turned to the teacher, and each child is given a 'protector," an intelligent child who sits near and explains to him what he fails to hear Ear trumpet devices are recommended for those who cannot otherwise hear their own voice, mainly so they can listen to and modulate their own voices The curved hand to promote hearing is also advised Lip reading is essential, and Laubi recommends Gutzmann's treatise on this subject (1912) A special school or classes are advisable for children who are unable to hear a whisper at 2 meters The teachers should be trained in the care of deafmutism, and Laubi deplores that there is no state examination in Switzerland, as there is in Germany, that guarantees special training for welfare work among the deaf He urges the organization of a school with three grades for the children with defective hearing, with special training to improve vision, and with extra manual training work The school might also, he says, include the children with eyesight requiring much correction The expense of such a school renders it impracticable at Zurich at present, but there is already valuable work being done in this line in five cities by a private organization, the Hephatavereine, which assembles the younger children and trains them in hearing exercises, and in the use of the voice, with gymnastics and games

43 **Regular Fluctuations of the Temperature**—Ammann reviews what has been written on this subject citing the findings on pigeons, monkeys and other animals and on man, in regard to the diurnal and nocturnal variations in the normal temperature He then tabulates the findings over a whole year in a healthy person with regular habits, not doing heavy work The temperature was taken on rising in the morning and just before going to bed, the thermometer held in the mouth for fifteen minutes each time There was an average daily variation and also an annual the body temperature gradually reaching its highest point in July and lowest in November, practically uninfluenced by the atmospheric temperature The fluctuation was 0 43 of a centigrade degree Ammann theorizes that the electricity in the air is responsible for the daily and yearly fluctuations

Medizinische Klinik, Berlin

November 19 1916 XII No 47 pp 1223 1248

44 *Venesection plus Autoserotherapy (Eigenserum und Aderlass—Lehre und Anwendung) B Spiethoff —p 1223 To be concluded

45 *To Expel the Blood in Operating on the Limbs (Kurze Bemerkung zur Blutleere bei Operationen von den Extremitaten) Ritter —p 1228

51 Indications for Obstetric Operations by the General Practitioner (Zur Indikationsstellung bei den geburtshilflichen Operationen des praktischen Arztes) H Walther —p 1236 To be continued

44 **Venesection Plus Autoserotherapy**—Spiethoff has apparently established that equally favorable results can be realized with the patient's own serum as with alien serotherapy The benefit does not depend on supplying certain lacking elements but on a broader principle, which includes the individual's own serum He here reports his favorable experiences with the method in a variety of skin diseases and acute general infectious diseases He draws from 50 to 100 c c of blood and reinjects into a vein the serum from this blood after coagulation The procedure is repeated on alternate days at first and then twice a week Or the venesection can be smaller, and 5 c c injected intravenously every day The dosage is extremely important He has never witnessed with this form of serotherapy anything like the phenomena of hypersusceptibility sometimes noted with foreign serum, but there is usually a transient general and a focal reaction Promising experiences are related with rebellious urticaria, eczema, pemphigus, scalp disease and gangrenous ulcers Pruritus at all ages offers an exceptionally grateful field for this technic If the favorable effect diminishes, he advises changing to Ringer's solution injecting 300 c c two or three times a week intravenously or subcutaneously Good results were obtained in the complications of gonorrhea, acute febrile swelling of the epididymis and prostate rapidly retrogressed in his experience

45 **To Expel the Blood from the Limb**—Ritter commends the principle of Trendelenburg's 'spit' (*Spiess*) for checking the flow of blood at the hip and shoulder When this special instrument is not available, the same result can be obtained *with long forceps or scissors* He has never had the constricting rubber tube slip He does not describe the technic

46 **Salvarsan in Pernicious Anemia**—Lämpe declares that he has never witnessed such pronounced and durable improvement from any other measures in pernicious anemia as he realized under salvarsan in the three cases described The patients were women of 40, 45 and 50, and the anemia was in a grave stage, the hemoglobin *30* per cent, reds 1,400,000, in the first case, with syncopes and hourly vomiting Under

six small doses of salvarsan—a total of 0 65 gm in five weeks—the patient rapidly improved and in four months the hemoglobin had risen to 70 per cent and the reds to 4,400 000 She felt quite well for seven months, but then symptoms of pernicious anemia returned and as the heart was weak no attempt to give salvarsan again was made Necropsy confirmed the diagnosis and the fatty degeneration of the heart Equally favorable results were obtained in the two other cases, the reds numbered 1 200 000 and 1 000 000 and both patients were restored to clinically perfect health and endurance Syphilis and helminthis could be excluded in all three cases, and under salvarsan the morphologic blood findings returned to normal A permanent cure can scarcely be expected, but the last two patients are still in good health The six or seven doses were 0 05 to 0 15 gm each, intravenously in the course of eight or fifteen weeks, and they were borne well as a rule

49 **Nervous Weakness of the Heart**—Singer calls attention to three tests which may reveal an organic basis for the apparently exclusively subjective disturbances One is an especially sensitive area near the heart a hyperesthetic zone, egg shaped or elliptic, near or including the left nipple When the needle is drawn lightly over the right breast and then over the left breast the patient shrinks and exclaims when this tender area is reached He gives illustrations of the area involved in eight cases The second test is what he calls the "vagus pulse" The anomaly in the vagus action is shown most instructively by the difference in the pulse during inspiration and expiration, and between the pulse lying down and sitting up The pulse also grows slower during the "squatting test", the man bends his knees several times and then stays in the squatting position the head bent forward while the pulse is counted It was materially retarded in the heart-neurosis cases dropping from 6 × 21 to 6 × 13, in one case from 6 × 25 during running to 6 × 12 while squatting The retardation is briefly transient In twenty healthy men there was no change in the pulse except in four cases and in these it lasted only for two or three beats But it is common in neuropaths and neurasthenics, even when there is no appreciable heart neurosis

Gazzetta degli Ospedali e delle Cliniche, Milan

December 7 1916 XXXVII No 98 pp 1537 1552

52 *The Various Forms of Purpura (Morbo di Werlhoff e trombopenia essenziale) G Matteucci—p 1539

December 10 No 99 pp 1553 1568

53 *Unusual Localizations of Paratyphoid B Infection A. Florenzano—p 1553

52 **Werlhof's Disease and Essential Deficiency in Thrombogen.**—Matteucci relates that his analysis of cases of purpura has shown that there are nine different varieties of this affection and that certain varieties are amenable to horse serum, while others are not modified by this but are corrected by administration of an extract of blood platelets He lists them as simple purpura, Schonlein's rheumatoid purpura, Majocchi's type with telangiectasis, Landouzy's infectious type, Henoch's fulminating form, Werlhof's disease, essential thrombopeny (Frank) and scorbutic and chronic purpura In two cases described in detail the difference between typical Werlhof's disease and essential thrombopeny is well brought out, and the benefit from horse serum in the first type and from extract of blood platelets in the second The patients were a boy of 16 and girl of 12 Examination of the blood classifies the cases In all varieties, epinephrin is liable to prove a valuable aid It was not needed in the first case, the horse serum answering the purpose alone The varieties of purpura are all of two types, those with and those without normal conditions in the blood platelets

53 **Unusual Localizations of Paratyphoid Infection**—Florenzano remarks that paratyphoid B infection is always a septicemia but the main focus of infection may be in various organs in different cases The disease may run a mild course in three or four days or it may last for three months with remittent or intermittent fever In a case described in detail the localization was in the pleura, and the symptoms from this had preceded the paratyphoid septicemia The disease ran its course through three months the toxi-infectious symptoms recurring in three attacks Tuberculin reactions were negative and great benefit was derived each time from injection into the pleural cavity of an antiparatyphoid vaccine In a second case the paratyphoid infection was installed predominantly in the colon and the symptoms suggested acute appendicitis in the course of the paratyphoid, but it apparently subsided and the patient recovered under medical measures alone In a third case the symptoms were those of acute appendicitis alone with constipation, no diarrhea as in other cases and there had been several days of malaise with fever and chills but nothing to suggest other intestinal trouble In still another case the paratyphoid B septicemia induced a hemorrhagic set of symptoms and then seemed to subside, the temperature becoming normal and the patient feeling well for a day then a severe typical paratyphoid fever set in, with fatal hemorrhage in the bowel One man of 39 had a combination of typhoid and paratyphoid but left the hospital in good condition after a two months' stay

61 Addison Syndrome in an Incomplete Form of Recklinghausen's Disease C V Lutati—p 1061

59 **The Nitrogen, Cholin and Cholesterin Content of the Cerebrospinal Fluid**—Cantieri gives the detailed findings in regard to the total nitrogen, the cholin and the cholesterin in the lumbar puncture fluid from thirty-one patients with different diseases There was no regularity to be detected in the cholin and cholesterin content, but the nitrogen content showed an increase in all disturbances of a toxic infectious character affecting the brain, or in disturbance from arteriosclerosis The nitrogen content was also liable to be high in psychoses and epilepsy, as well as with uremic derangement, but with brain tumors there was no increase An extensive bibliography is appended

60 ***Minor Long Continued Fevers***—In a few specimen cases reported, the patients were women in the thirties, a young man and some children Each for a year or two or more had had weeks of depression and slightly abnormal rise in temperature over long periods, for which absolutely no cause could be discovered Rossi comes to the conclusion that the explanation must be some upset in the innervation of the glands with an internal secretion There was nothing to suggest hysteria in any of the cases, but the general nutritional processes seemed below par and functional nervous disturbances of various kinds were manifest

67 *Pathologic Anatomy of Dermal Leishmaniasis (Anatomia patologica de las Leishmaniasis dermicas) G Almenara —p 429

62 **Identity of Peruvian Verruga and Oroya Fever** —Arce protests against the conclusions of the report of the Harvard commission on Peruvian verruga (It was published in The Journal, Nov 8, 1913, p 1713) The commission decided that Peruvian verruga and Oroya fever are separate diseases The fact that the same germs were found in both at times, they ascribed to mixed infection But Arce's long years of practice in Peru have confirmed him more and more in the view that they are the benign and the malignant forms of one and the same disease Arce is professor of tropical medicine in the University of Lima, and he presents an array of arguments to invalidate the commission's conclusions Different persons react differently according to their defensive powers, and the germs may differ, they may be represented by two different species or varieties as we know to be the case with the malaria germ The Harvard commission fully established the inoculability from man to man of Peruvian verruga, thus confirming Carrion's work Arce asserts in conclusion that there is no proof as to the zooparasitic nature of the inclusions in the red corpuscles which they call *Bartonia bacilliformis* Arce exclaims "How can we explain these and similar mistakes made by men of unquestionable scientific authority? We must acknowledge the great and multiple difficulties presented in the study of the infinitely small, and of all research in the field of the red blood corpuscle, this highly specialized minute organ, differentiated for its functional perfection, the elective affinity for and fixation of oxygen, but losing in the meanwhile two of the fundamental attributes of the cell the nucleus and the power of reproduction The physiopathology of the red corpuscles is still full of surprises, even under normal conditions, and the pathologic erythrocyte offers a broad field for discussion and erroneous conclusions"

63 **Postoperative Acute Dilatation of the Stomach** —Valle Riestra reports four cases in Denegri's service and three in Carvallo's, all presenting the clinical picture of acute arteriomesenteric occlusion of the duodenum, with extreme dilatation of the stomach Necropsy in the two fatal cases in the last group showed the typical compression of the duodenum by the mesenteric artery, owing to the acute dilatation of the stomach The symptoms in these cases had been ascribed to a nonexistent peritonitis In the others, the correct diagnosis was made in time, and lavage and the knee-chest posture brought the patients through The cause seemed to be the anesthetic plus preceding weakness of the stomach, with or without a tendency to peritonitis, in all but one case In this the acute dilatation developed under the physician's eyes almost entirely from swallowing air This case teaches the necessity for being on the alert to prevent swallowing of air The Trendelenburg position wards off the compression of the duodenum by the artery It can be alternated with the knee-chest posture Chambard insists that no fluid should be allowed by the mouth, and thirst should be combated by the rectum drop method

67 **Dermal Leishmaniasis** —Nearly the whole of this issue of the *Cronica Medica* is devoted to Almenara's illustrated study of the pathologic anatomy and histology of the various forms of superficial lesions caused by the leishmania They can all be classed as the ulcerative or the tubercle types, the latter subject also to ulceration and crust production The ulcerative type is called uta hembra, espundia, juccuya and tiacaraña, the tubercle type is called Oriental sore, uta macho and qcepo In all the cases examined the leishmania was found in the tissues, free in the lymph and plasma or incorporated in the large mononuclear cells

74 Associated Reflexes (Asociacion de reflejos—sinreflexias) A Austregesilo and T Mendez —p 352

70 **Dosage of Urea in the Blood Serum** —Landolph commends a method for this purpose which has proved simple and satisfactory in his hands He mixes 2 c c of the serum with 2 c c water and from 1 5 to 2 c c of pure hydrochloric acid This is brought to the boiling point for a moment and then filtered through a small filter with folds It speedily filters through and the residue on the filter is washed with 4 c c water The filtered fluid is treated directly with 20 or 30 c c of sodium hypobromite in the A Robin ureometer Practically all of the nitrogenous compounds capable of yielding nitrogen as urea are eliminated by this procedure which, he thinks, reduces the sources of error to the minimum

71 **Emergency Dilatation of Uterine Cervix** —Fernandez advocates incising the cervix rather than attempting to dilate it by mechanical means when the pregnancy is in the last half He has thus operated on eight women with progressive tuberculosis or other cause requiring prompt evacuation of the uterus The effects were excellent and two of the women have passed since through a normal pregnancy

84 *Periodic Leukocytosis V M Sokoloff —p 997

82 **The First Dentition**—Karnitzky protests against Heubner s energy' theory of the first dentition, saying that the same laws which regulate growth and development at all ages govern them at the first dentition as later He has been making a special study of conditions affecting the first dentition, and tabulates data from 5,735 children, including 2,143 under 12 months old, all with affections of the respiratory apparatus, and also the data from 13 151 with digestive disturbances, including 4,249 under 6 months old and 3 402 from 6 to 12 months, and also a long list of apparently healthy children Analysis of all this material confirms the frequency of pathologic conditions in infants particularly between the sixth and twelfth months when they begin to have more intercourse with the external world—just the months when the teeth are developing Not only the well defined pathologic states, but possibly overlooked stomatitis slight sore throat, slight grippe, a touch of typhoid, slight intermittent fever, lymphangitis in the neck, and so on These conditions may affect the development of the teeth under the same laws as regulate conditions in adults The formation of the teeth may be diverted from normal, and there may be pathologic local processes in the teeth, defects in the dentine or enamel, pulpitis and carious processes in the teeth after they cut through In short, he declares, instead of theorizing about the first dentition examine the babies mouths, and much that is surprising will be learnt, when the children are below par in any way or the parents at the time of conception were not entirely healthy

84 **Periodic Leukocytosis**—Sokoloff adds another to the imposing array of works issued by Boldireff and his pupils, of the university of Kazan, on the periodical fluctuations in the functioning of the vital processes, especially of the digestive tract outside of digestion This article gives tables of details of tests on thirty-three dogs to show the fluctuations in the leukocyte count during exercise and during rest Changes of 6 000 in the figure were by no means uncommon, the higher figures being encountered during exercise and when the digestive tract was most active The conclusion is drawn that the leukocytosis is elicited by the action of ferments in the digestive juices the pancreatic and intestinal juices, during exercise these juices are forced out into the blood stream in larger proportions The fluctuations average about the same as with the leukocytosis of digestion, sometimes one and sometimes the other being highest The bibliography on this special research is appended including a number of theses both at Kazan and Petrograd All are in Russian except an early communication from Boldireff in the *Ergebnisse der Physiologie* 1911 Some have been summarized in these columns, as, in The Journal, Oct 9, 1915, p 1316 Nikulin s article on periodical vomiting

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

November 18 1916 II No 21 pp 1849 1920

85 *Snapping Hip (Over de veerende heup ziekte van Perrin Ferraton) G Kapsenberg—p 1849
86 The Visual Field as Guide to Operating in Glaucoma (Gezichtsveldonderzoek en glaucoomoperatie) D J Waardenburg—p 1866
87 *Urine Containing Indigo Red (Indigoroodhoudende urine.) L de Jager—p 1873
88 *Present Status of Prophylaxis of Scarlet Fever (De tegenwoordige roodvonkbestrijding) H G Ringeling—p 1874

85 **Snapping Hip**—Kapsenberg discusses with illustrations the mechanism of typical and atypical snapping hip and reports a few cases to show the different factors that may be involved In the typical form it is caused by the abnormally taut fasciogluteal fibers springing over the major trochanter The jerk of the snap is accompanied by a click The snapping can be done voluntarily, in which case there is no pain, or the snapping occurs automatically and is usually accompanied by some pain The snapping may be from the iliopsoas muscle, above the greater trochanter In a case in his own practice a young man had fallen on the right buttock and there was pain in the region and hip joint and some stiffness in the leg but nothing abnormal could be detected to explain the pain *in the buttock* when *the hip joint* was moved and the snap when this thigh was flexed or extended The jerk and snap were most pronounced as the man reclined and moved his hip joint, the jerk being felt through the whole leg The click seemed to come from the hip joint It resembled the noise made when a reducible dislocation is reduced The movements of the leg were normal at all times, but in running or climbing stairs the snapping phenomenon occurred occasionally There was no snapping across the greater trochanter, but a distinct jerking movement could be seen in and felt in the tissues close to the anterior superior iliac spine, in front of the attachment of the sartorius muscle Roentgenoscopy showed apparently normal conditions, but a very taut tendon was found deep below the surface It was evidently responsible for the snapping as it moved to and fro across a bony projection The tendon was about 1 cm broad and evidently belonged to the iliopsoas muscle It was severed and the upper stump sprang back out of sight The snapping was cured at once, but the man still has some pain in the region and later the hip joint and knee on the other side have become painful, showing a general tendency to joint troubles This tendency may have been responsible for *some change in the bone which may have caused indirectly* the snapping of the tendon

87 **Indigo Red in the Urine**—De Jager recently had a specimen of urine sent in for examination which contained albumin and, supposedly, blood as it was reddish, but no red corpuscles could be detected in the sediment and the reaction was alkaline The patient was an unmarried woman of 88 The guaiac and benzidin tests for blood gave negative findings, and other tests proved the coloring matter to be indigo red He thinks it liable that this has sometimes been mistaken for blood

88 **Hospital Treatment in Prophylaxis of Scarlet Fever**—Ringeling says that the known cases of scarlet fever in Amsterdam for the months of August, September and October have been in 1912, 1915 and 1916, respectively, 1 566, 673 and 1 147 He has seen return cases develop after 46, 48 49, 55, 75 and 88 days of hospital treatment of the scarlet fever with every possible means of prophylaxis applied For this and for other reasons, especially when we reflect that the healthy bacilli carriers cannot be isolated, it seems that not much can be anticipated from hospital treatment of scarlet fever in general prophylaxis of the disease, but the families are thus released from the annoyance of quarantine, which is a great advantage He warns further that scarlet fever is a treacherous disease An apparently mild case may have severe complications and may transmit the disease to others in a severe form The mortality in the recent epidemics has been only 0 32, 0 74 and 2 18 per cent of the notified cases, and he queries whether the prompt hospital treatment may not have been the decisive factor in this low mortality In 1915, fully 80 per cent were taken to the hospital and only 0 74 per cent. died Statistics from London are cited showing how the mortality of the known cases has dropped from 5 6 per cent. to 2 since 1890, in inverse proportion to the percentage of cases taken to the hospital This was 42 8 per cent, with a mortality of 5 6 per cent in 1890, the total number of cases being 3 7 per thousand inhabitants The figures in 1910 were 85 6 per cent in the hospital, mortality 2 per cent the number of known cases being 2 5 per thousand inhabitants In short Ringeling declares, progress is to be realized by taking more and more the cases of infectious diseases of all kinds to the hospitals

Supplement pp 1 78

93 *Fibromas Sarcomas and Mixed Tumors of the Ovaries and Results of Operative Treatment (Undersokning ofver lakningsresultaten vid den operativa behandlingen af desmoida ovarialtumörer) M af Heurlin—p 1

89 **Traumatic Rupture of Internal Organs**—Krogius gives a number of illustrations to show the various types of rupture of the spleen, liver and other organs under the influence of contusions bending or squeezing them When the force bends the organ, the rupture is on the convex side and runs perpendicularly to the force applied, the edges of the rupture are sharp, and the rupture is more extensive on the surface than below Rupture from compression runs parallel to the force, and may occur on both sides of the organ The rupture extends more in the depths than on the surface, and the edges are torn and uneven These features of rupturing may be useful in criminal cases to determine the character of the force applied In making tests on the cadaver, the organs must have fluid injected to bring them up to the physiologic tonus

90 **Sodium Citrate in Treatment of Glaucoma**—Gronholm's experience was disappointing He injected the 4 05 or 5 41 per cent solution of sodium citrate, making thirty-three subconjunctival injections in four cases, including two eyes with inflammatory glaucoma, two with simple glaucoma and two with absolute glaucoma Pain and swelling followed in the acutely inflamed glaucomatous eyes, but there was no modification in the pressure In the other cases benefit was apparent, the pressure in some of the eyes returning to normal But this effect proved transitory It is possible that this treatment might prove effectual in combination with myotics, but it cannot compete with operative measures

91 **Spontaneous Pneumothorax in Pulmonary Tuberculosis**—Bonsdorff concludes from his experience in nineteen cases of this kind that treatment should aim to transform the spontaneous pneumothorax into a seropneumothorax or serothorax, and then, as soon as the fistula has healed, to aspirate the effusion and introduce nitrogen in its place, keeping up the artificial pneumothorax as long as conditions require This method was applied in three of his cases and proved completely successful in two In the third case the fistula refused to heal

92 **Hydrosalpinx**—Jagerroos' long study of this subject fills sixty-four pages, including two devoted to bibliography It is based on 100 clinical cases As conservative operative treatment is the rule, only fifty-eight pathologic anatomic specimens were obtained There are no especially characteristic symptoms, he says, so that it is almost impossible to determine beforehand the exact nature of the trouble Conservatism was carried to the extreme, and recent reexamination of seventy of the 100 women showed forty-five entirely cured of all disturbances to date, after salpingotomy In three cases the hydrosalpinx returned on the other side In fourteen cases treated with salpingostomy, the results have been entirely satisfactory, in two other cases a tumor developed later on that side One woman has passed through a normal pregnancy since In five cases there is still some subjective disturbance although the objective findings are normal

93 **Ovarian Fibromas and Sarcomas**—Af Heurlin's profusely and handsomely illustrated monograph is based on 45 ovarian tumors of the fibroma and fibrosarcoma types He reviews the literature on the subject of desmoid ovarian tumors The article proceeds from the gynecologic clinic in charge of Engstrom The fibromas formed 1 9 per cent and the sarcomas 3 6 per cent of the total 688 operative ovarian tumor cases at the clinic The malignant sarcomas were bilateral in 50 per cent of these 9 cases, while only 12 5 per cent of the spindle-cell sarcomas involved both sides The fibromas never invaded both ovaries The average age in the spindle-cell sarcoma cases was 47 1 years, while 2 of the other sarcoma patients were between 18 and 19, 2 between 20 and 24, 4 between 35 and 40, and 1 between 40 and 45 One of the fibroma patients had exophthalmic goiter and died from embolism the second week The others are all in good health from four to nineteen years since the operation The mortality in the spindle-cell sarcoma cases was 12 5 per cent A similar proportion are living four years since the operation, while 50 per cent are living after an interval of from six to twenty-three years In the 9 malignant sarcoma cases, 33 per cent died soon after the operation and only 2 are still living, one only recently operated on, the other after an interval of twenty-two months The others died from recurrence in from two to fourteen months These types of ovarian tumors are encountered, according to his statistics, in a ratio of one to every 20,000 inhabitants One case per year of ovarian fibroma would correspond to 1,000,000 inhabitants, one spindle-cell sarcoma to 800,000, and one malignant sarcoma to 1,500,000 These figures are based on the population of Finland in 1914, namely 3,269,253 This is a lower percentage than in Sweden and Denmark

Ugeskrift for Læger, Copenhagen

96 *The Sugar Content of the Blood (Nogle Bemærkninger om Blodsukkerbestemmelsernes Teknik og nogle Iagttagelser over Blodsukkerets Forhold ved lette Glykosurier) F Rydgaard—p 2007

97 Quantitative Determination of Albumin in the Urine (Nogle Bemærkninger om kvantitativ Bestemmelse af Aeggehvide i Urinen spec om 'Esbachs Metode' og dens Modifikation ved Gad Andresen) E Biering Petersen—p 2089

94 **Rupture of the Spleen**—In Hansen's two cases both of the patients recovered after removal of the spleen which had been split into two parts The symptoms of the intraperitoneal hemorrhage in one case were all in the right side, which was misleading, but was explained by the fact that the left side of the bed stood against the wall, so the lad of 16 had to lie on his right side as there was much vomiting and collapse The other patient, a woman of 38, had signs of peritoneal irritation but it was not severe and the trauma seemed insignificant and the general condition kept good Possibly the morphin that had been given had contributed to this There was much less loose blood than in the first case, although the operation came in three and a half hours in this and not until after twenty-four hours in the second case, the bleeding in the latter being intermittent Adhesions may check it, as these break up, more blood escapes An enlarged spleen ruptures more readily, in these cases the spleen weighed 160 and 280 gm In Berger's compilation of 168 cases, 50 per cent died within the first hour and 25 per cent between the second and the tenth

95 **Phototherapy of Tuberculosis in Danish Sanatoriums**—Hansen reviews the work being done with arc lights and mercury vapor lamps in the various sanatoriums, including the one in his own charge He soon abandoned the arc lamps as uncontrollable, and now works exclusively with the mercury vapor lamp The general impression is favorable for superficial accessible lesions but not for others

96 **Determination of Sugar Content of the Blood**—Rydgaard describes the technic with which it is possible to determine the absolute values as well as the relative in testing the sugar content of the blood He uses Bang's second micromethod—the uranyl acetate method—as this is more exact than the precipitation with salt solution method Even with the former, a number of minor technical points must be observed to get satisfactory results, as he describes in detail from his own experience In connection therewith he discusses the sugar content of the blood with slight glycosuria, citing some cases of the latter with diametrically opposite sugar content of the blood and clinical course He queries whether they represent different morbid entities or are merely various manifestations of diabetes mellitus In the one type the glycosuria was a casual discovery and it did not seem to depend on the diet, not increasing on a full diet and not decreasing on the antidiabetic diet, while the sugar content of the blood was within normal range and there was nothing otherwise to suggest diabetes In the case of the other type, the glycosuria responded promptly to dietetic measures but the sugar content of the blood corresponded to that of actual diabetes throughout the tests

MECHANICAL DERANGEMENTS OF THE KNEE JOINT *

MELVIN S HENDERSON, MD
ROCHESTER, MINN

Mechanical derangements of the knee joint are relatively common and may be due to either extrinsic causes such as exostoses, or to intrinsic causes such as fractured internal semilunar cartilage It is to the latter, which are the most difficult to diagnose, that attention will be drawn in this paper

ANATOMY

The knee joint is a hinge joint While nature was apparently most lax in providing bony reinforcements to the knee, she has been most ingenious in furnishing ligaments strong enough to take up the strains imposed In front is the anterior or big patellar ligament This has a ligamentous or tendinous attachment below and a muscular attachment above Its action as a true ligament, therefore, is not very great On the inner side is the internal lateral ligament, short, strong and fan shaped, with its narrow part downward, and having its deep portion intimately associated with the capsule and the internal semilunar cartilage The deep fibers, being short, keep the internal semilunar close to the condyles of the femur On the outer side the external lateral ligament extends from the external tuberosity of the femur to the head of the fibula, splitting the tendon of the biceps in its course This ligament has two divisions, a weak posterior part and a strong anterior part It is separated from the capsule of the joint by the popliteus tendon and the bursa found there The two lateral ligaments are the chief agents in providing against lateral mobility, the internal lateral preventing the knee from bending outward, and the external lateral preventing the knee from bending inward The rounded ends of the femur are buttressed, as it were, by the internal and external semilunar cartilages, and thus the lateral ligaments are aided in their function (Fig 1)

The internal semilunar cartilage forms a large segment of a circle and is less movable than the external

damage

The external semilunar cartilage forms a smaller segment of a circle Occasionally it is nearly a complete circle, there being only a small opening against the tibial spine, as in three of the 150 specimens examined by Tenney[1] The external semilunar is fixed anteriorly in front of the tibial spine, and posteriorly to the tibial spine between the tubercles, giving a strong slip to the posterior crucial ligament The attachments to the external lateral ligaments and the tibia are very weak The semilunar bodies are spoken of as being cartilaginous In reality, they are fibrocartilaginous, the thick convex part being largely fibrous tissue, and only the inner concave portion cartilaginous When this cartilaginous border is injured, small pieces of cartilage may become separated and loose The fibrous tissue is arranged transversely and longitudinally The longitudinal fibers may continue anteriorly across to the opposite cartilage forming the transverse ligament—an insignificant structure At the convex borders, the transverse fibers blend with the capsule The coronary ligaments are formed by these fibers below and are really only the portion of the capsule between the semilunars and the tibia

The anterior and posterior cru[illegible]nts are two very important internal ligaments The ant[illegible] from the front of the spine of the tibia near the anterior extremity of the external semilunar cartilage and courses upward, outward and backward to the inner side of the outer condyle of the femur The posterior arises from the back of the groove on the posterior side of the top of the tibia and from its outer border, leaving the floor of the groove and the transverse piece of the spine of the tibia free and covered by synovial membrane Here it is closely connected with the external semilunar cartilage and runs forward, upward and a little inward to the front of the outer side of the inner condyle of the femur and of the intercondylar notch (Piersol[2]) These ligaments greatly aid in the stability of the joint Griffiths[3] states that if the internal or external lateral ligament is divided and lateral bending is attempted with the knee extended, the bending allowed is considerable, but if the same is attempted with the knee in the flexed position no bending is allowed laterally He concludes, therefore, that inward bending of the knee joint is prevented in the extended position by the internal lateral ligament; and in the flexed position by the crucials In flexion the relaxation of the internal lateral ligament allows some rotation With the knee partially flexed, extension may pull on the anterior or upper part of the

internal lateral ligament and thus make some traction directly on the internal semilunar cartilage, there being a few fibers of the quadriceps inserted there This may explain why the anterior extremity of this cartilage occasionally becomes caught and ripped Jones[4] says experiments show that hyperextension of the knee is prevented by (1) the posterior crucial, (2) the anterior crucial, (3) the internal lateral ligament, (4) the external lateral ligament, and that increased extension is secured as one after another of these is divided Internal rotation is limited by the internal lateral ligament and the anterior crucial In external rotation the tibia may slip slightly forward on the femur but is stopped by the anterior crucial On internal rotation the tibia may slip back a little but is stopped by the posterior crucial

Mechanical derangements produced by intrinsic causes will be considered under the following heads

1 Semilunar cartilages
2 Loose bodies
   (a) Of intrinsic origin — chondral and osteochondral bodies
   (b) Of extrinsic origin — foreign bodies
3 Synovial fringes
4 Crucial ligaments

DERANGEMENTS DUE TO THE SEMILUNAR CARTILAGES

In the English medical literature there are many reports of large series of cases of damage to the semilunar cartilages, but those reported in the American literature are few This is accounted for largely, I believe, by the fact that the English, as a class, participate much more freely in vigorous pastimes such as football, Rugby, tennis, hockey, etc, than do Americans In America the clerk or laboring man seldom indulges in such pastimes, while in England he participates in them freely

As stated previously, when the knee joint is partially flexed a little lateral mobility is permitted This is due to the fact that the internal lateral ligament is relaxed As it slacks, however, the crucial ligaments take up their duties so that when the knee is at right angles, the lateral mobility is checked From 25 to 90 degrees' flexion is an arc of weakness, and it is in this arc that damage to the internal semilunar is most frequently inflicted According to Jones,[5] the most frequent cause of injury to the internal meniscus is strain thrown on the internal lateral ligament when the tibia is rotated outward while the knee is flexed In rare instances he has known it to occur when the knee was extended, but, as emphasized by Lane,[6] the internal fibrocartilage is injured in such cases only by great force In extension, the internal lateral ligament is taut and performing its function, and it must be torn before the internal semilunar fibrocartilage can be displaced In moderate flexion the crucials are not in a position to maintain stability, and the internal lateral ligament being slightly relaxed, some mobility of the internal semilunar is allowed On attempted extension there may be a slight pull on the anterior extremity of the semilunar cartilage by the prolongation of the quadriceps muscle inserted into that part of the capsule, and the cartilage may be caught between the joint surfaces and torn loose or possibly fractured as the leg is straightened Martin[7] states that damage to the internal semilunar is common among coal miners who stand with the knees more or less flexed in low seams (4 by 4½ feet) in the mines A review of our case histories has demonstrated that in the majority of instances the accident occurred with the leg partially flexed, the foot abducted and rotated outward, and force applied which caused the tibia to be rotated outward or the femur to be rotated inward, depending on whether the force was applied above or below the plane of the knee

Locking of the joint is followed by effusion The pain is often so severe as to make the patient cry out and fall to the ground, grasping the knee with both hands It is usually most severe at the primary locking, and lessens as the locking becomes more frequent, until by some patients the pain is complained of less than the mechanical obstruction blocking the extension of the leg The effusion may be considerable following the early locking, but as the lockings become more frequent the joint seems to accustom itself to the condition, and very little if any appreciable amount is noted In some cases the locking may not be distinct, the patient complaining only that "things do not feel right in the joint" A diagnosis of a damaged fibrocartilage should be made in such cases only after very careful examination and consideration The roentgenogram is of practically no aid, as in the great majority of instances the fibrocartilaginous body of the misplaced cartilage casts no shadow Occasionally in persons with a history of lockings extending over many years the irritation inflicted on a pedunculated end of the internal semilunar will so harden it that a faint shadow will show in the roentgenogram between the internal condyle of the femur and the tuberosity of the tibia In such cases, however, the history is usually so clear that the roentgenogram is not a necessary aid in the diagnosis Nevertheless, any patient with mechanical derangement of the knee should have the benefit of the roentgenographic examination, for it is impossible to differentiate in many cases between a misplaced or loose internal semilunar or external semilunar cartilage and a loose body The roentgenogram, therefore, may be considered as of the greatest aid in making a differential diagnosis

It must be constantly borne in mind that while the most frequent cause of mechanical derangement of the knee joint is an injured internal meniscus, other causes also may produce the derangement In some instances a diagnosis is extremely difficult before operation, and even after the joint is opened the cause is not evident Surgeons of great experience have acknowledged that occasionally after making a careful search for the condition causing the symptoms complained of, they have closed the knee joint without repairing or removing anything The removal of the internal semilunar cartilage must be decided from the findings

According to Lane,[6] periodic derangements of the knee joint may so lower the vitality of the joint tiss[illegible] that tuberculosis develops In his opinion the [illegible]ity of cases of tuberculosis of the knee joint [illegible]ontent as their predisposing factor, particularly in [illegible]othing who have intestinal stasis In this content[illegible]r type, supported by Jones,[4] who adds that th[illegible]es bu[illegible]f actual arthritis also may be so induced. I have seen a few cases of tuberculosis of the knee in which there was a history of mechanical derangements for some years preceding the onset of the tuberculous arthritis. Such a history, however, was the exception rather than the rule.

[7] Martin A M Discussion on the Diagnosis and Injuries of the Knee Joint Other than Fractures and Brit Med Jour 1913 2 1070

The treatment of derangement due to the internal semilunar cartilage is either nonoperative or operative. It may be taken as a rule that patients should not be operated on who give a history of only one locking. If seen immediately after the accident, reduction should be made at once. Complete extension, and the statement of the patient that the joint feels right, is evidence that reduction of the displaced cartilage has been effected. If the patient insists that the reduction is not accomplished, it is probable that he is correct. After successful reduction, rest in bed should be insisted on until the effusion has subsided. Flexion of the knee and strain on the internal lateral ligament should be prevented for six weeks. If the damaged cartilage is given the opportunity to unite firmly in its normal position, the chances for a cure are very good. If the primary care has been careless and the fixation period inadequate, the patient very often presents himself with a story of multiple lockings. In these old cases, operative interference is necessary, for rest and immobilization at this late time will not insure the fixation of the loose cartilage in its normal position. When operation is necessary for removal of the internal meniscus, the incision of choice is the condylar incision of Jones. It is not necessary to remove the entire cartilage, the anterior three fifths is usually sufficient. Damage to the internal lateral ligament may be avoided by limiting the incision and by leaving a thin rim of the fibrocartilage attached to the internal lateral wall of the joint. This can be done easily by using a tenotomy knife to separate the cartilage, thus avoiding the deep fibers of the internal lateral ligament.

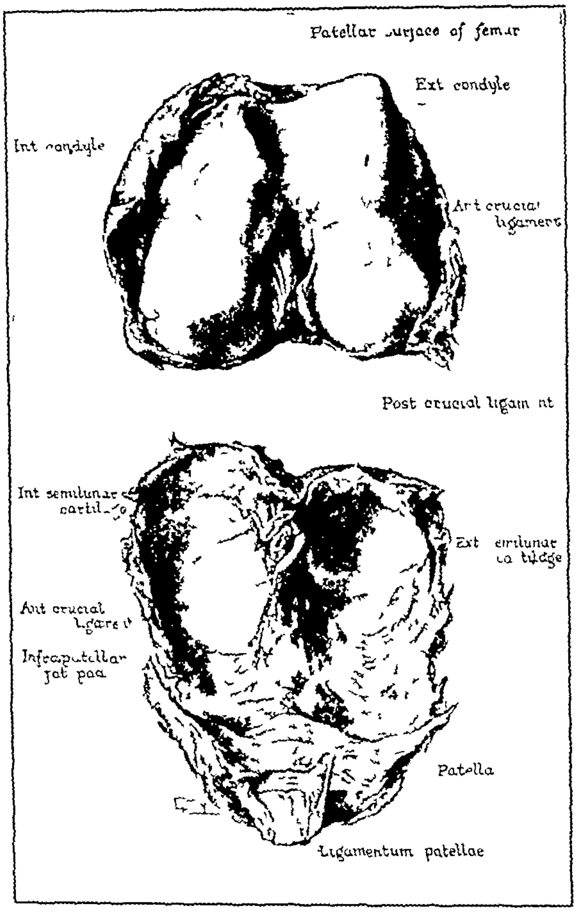

Fig 1.—Intrinsic structures of the knee joint.

In my series of cases there has been none in which we have found it necessary to remove the external semilunar cartilage. Jones[4] found it necessary to remove it in twenty-four cases, 7 per cent of his total. He explains the rarity of damage to this cartilage on the ground that, unlike the internal semilunar which is securely fastened by its ligaments and cannot slide out of the way of harm, the external semilunar is more loosely attached and thus escapes injury. However, it should be borne in mind when making a diagnosis that the external cartilage is not immune to damage.

LOOSE CHONDRAL AND OSTEOCHONDRAL BODIES

Relatively speaking, loose bodies of cartilaginous or osteocartilaginous consistency are common. They may be either free or pedunculated. Very often when the body is cast off from one of the articular surfaces a piece of spongy bone comes with it. As the body wanders about the joint it receives nourishment sufficient to permit the growth of cartilage until it is entirely covered. Then only by section of the body can the bone be demonstrated (Fig 2).

The etiology of loose bodies is interesting. It is generally conceded that a certain definite group have ostearthritis or Charcot's disease of the joint as their primary cause. This group, however, does not directly concern the surgical aspect of the subject, for in such cases the disease is more important than the mechanical difficulties, which are only incidental. The majority of loose bodies in the knee joint cannot be explained on these grounds, and it is this majority that is of the greatest interest. Whitelocke[8] believes that many of them have their origin in the fibrous tags that hang from the synovial membrane. He states that as the synovial membrane, articular cartilages and interarticular cartilages are developed from the same primitive embryonic intermediate layer of the axial blastema, these fibrous tags may readily develop into loose bodies of chondral nature. Koenig,[9] on the other hand, described osteochondritis dissecans as being the cause of loose bodies. Ridlon[10] and Freiberg[11] have more recently called our attention to this condition and reported cases. Briefly, it is supposed that the pathology causing osteochondritis dissecans is a blocking of one of the nutrient end-arteries supplying the joint surfaces, with a consequent desiccation of the localized devitalized area as a free or pedunculated body. Undoubtedly there are such cases. However, it is very difficult to estimate the amount of trauma that may be inflicted on a joint surface by the crushing force exerted on attempted extension of the knee by a curled or crumpled up semilunar cartilage. Owing to its fibrocartilaginous structure, the semilunar cartilage may itself escape any serious damage and yet severely injure the cartilaginous articular surface. In the majority of instances no history is to be elicited of a tendency to form loose bodies, but there is a history of direct injury to the internal condyle of the femur by falling on the flexed knee The injured area may be chipped off at the time, but more often the area of trauma is devitalized and later separates off and becomes a free body In the greater number of our cases of loose bodies in the knee joint we were able to demonstrate either by the Roentgen ray or operation that the bodies originated from the thick ridge of the cartilage placed on the internal condyle of the femur to compensate for the wear caused by the normal action of the joint (Fig 3)

The symptoms are catching or locking of the joint accompanied by pain and followed by swelling Repeated attacks generally tend to decrease the severity of all the symptoms Very often the patient is able to locate the body and thus establish the diagnosis The Roentgen ray in practically all instances discloses the presence of the body, as the cartilage is usually dense enough to cast a shadow, and in many instances a small flake of bone is attached to the cartilage which further aids in the localization The continued presence of these bodies in a joint causes continued irritation and is apt to produce arthritis They should be removed, therefore, but before operation care should be taken to locate them as accurately as possible After the preparation of the knee has been completed, it may be possible to localize the body in the suprapatellar pouch or at either side of the ligamentum patellae By holding the body between the fingers and infiltrating the skin with local anesthesia a sharp needle may be pushed through the skin into the body to hold it securely A small incision down the course of the needle then allows ready removal of the body More often, however, the body cannot be grasped in this manner and in such cases general anesthesia and an incision allowing the best approach to the body is necessary If the body rests in the anterior compartment of the joint and on the inner side, the incision on the inner side of the patella permits the easiest entrance When a more general exploration is necessary, the splitting of the patella as described by Corner[12] allows free inspection of the suprapatellar pouch and the anterior and interarticular areas of the joint If the body is posterior, the incision described by Brackett and Osgood[13] through the popliteal space is the most convenient The mere presence of a loose body in the posterior part of the joint does not demand its removal Moreover, it should be remembered that occasionally there are sesamoid bones in the hamstrings that are extremely difficult to differentiate A sesamoid bone may have a concave surface that fits the convex posterior surface of the condyle of the femur, whereas the loose body, because of its wandering, does not have the shape of its location impressed on it, and is often rounded or oblong Stereoscopic roentgenograms may show whether the body casting the shadow is resting directly on the condylar surface or is located in the intercondylar notch If in the intercondylar notch, it is presumably a loose body, but if resting on the condyle it probably is a sesamoid

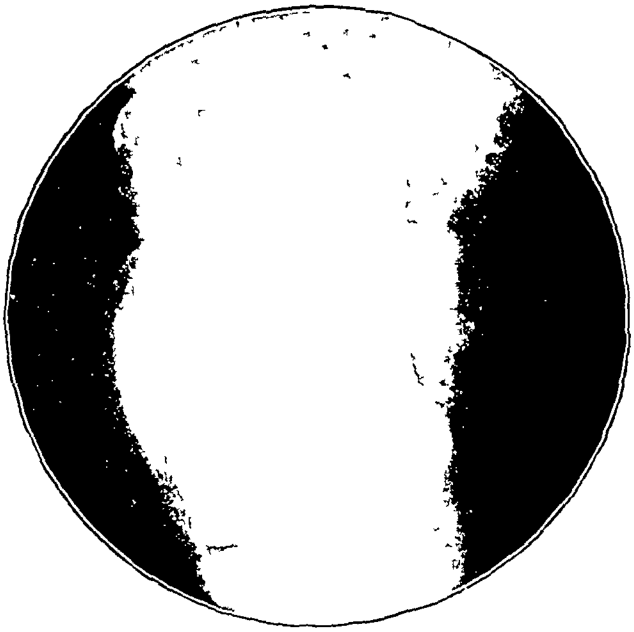

Fig 2 (116019) —Anteroposterior view showing loose body at site of origin in internal condyle of the left femur

FOREIGN BODIES

Foreign bodies cause derangements but differ from the previous groups mentioned in that they are of extrinsic origin, being introduced accidentally or intentionally from without In the literature, needles are mentioned frequently as a finding In some instances the patient is not aware of the introduction of the needle Malingerers occasionally introduce needles in the knee joint, and the clinical picture is baffling until a roentgenogram is taken Bullets may enter the joint and be remarkably well tolerated The presence of a foreign body in practically all instances demands the same operative measures as mentioned for the loose cartilaginous bodies, except that the demand for its removal is even more urgent

SYNOVIAL FRINGES

Synovial fringes or fat tags occasionally cause mechanical derangements, but the symptoms are usually mild The condition may be due to mild tuberculosis or to some systemic disease, such as syphilis These facts, together with the mildness of the symptoms, usually contraindicate operative interference Such tags, as a rule, have their origin on the alar ligament or the fat pad extending on either side of the patellar ligament Occasionally during the course of an exploration of the joint I have removed a pedunculated flattened fat tag which looked as though it were being habitually squeezed by the articular surfaces However, that the fat tag may be the sole cause of joint derangement has not in our cases been shown to my satisfaction Painter and Erving[14] have called attention to the possibility that fat tags may cause symptoms, and have reported cases

THE CRUCIAL LIGAMENTS

The results of rupture of one or both of the crucial ligaments are more serious and disabling than those of what are generally understood as mechanical derangements of the knee joint Their cause is severe trauma, such as that resulting from the passing of a wagon wheel over the leg If after an injury with the knee in an extended position the tibia can be pushed forward, the anterior crucial is ruptured If, with the knee in flexion, the tibia can be pushed backward, the posterior crucial is ruptured The pain caused by such extensive manipulations usually necessitates an anesthetic The spines of the tibia may be broken in addition, and occasionally give rise to loose bodies For ruptured crucial ligaments, Corner has advised operative measures However, when the knee is properly treated from the onset by placing it at rest in slight flexion in a plaster of Paris cast and maintaining such fixation for three months, a useful knee results It is tersely stated by Jones and Smith[15] that "modern practice pays not enough attention to the fact that a ruptured tendon or ligament must not be subjected to strain during the period of healing" Use of an injured knee should be permitted only after careful examination According to these authors, in a case of rupture of both crucials, conservative measures of rest for three to six months promise better results than immediate operation It is astonishing to what extent, particularly in the young, a knee with relaxed ligaments will regain stability if a suitable brace is provided to prevent strain on the stretched ligaments

END-RESULTS

The cases forming the basis of this report number eighty-seven They were all under observation in the Mayo Clinic during the interval between Jan 1, 1910, and Jan 1, 1916 As many of the patients as possible have been seen or communicated with since their operation, to ascertain the end-result of the treatment accorded them There were sixty-three males and twenty-four females The youngest was 14 years of age, and the oldest 67 The average age was 32 years

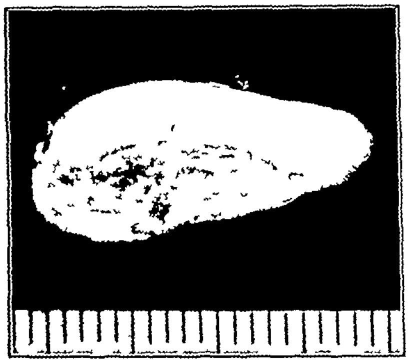

Fig 3 (147988) —Cross section of loose body showing cartilage grown around the bone × 2¼

The internal semilunar cartilage was judged to be the sole offender and removed in fifty-three cases We were able to trace forty-four of these patients Thirty were cured, nine were relieved and five reported themselves as no better It is probable that a few of the nine reporting themselves as merely relieved may be considered cured, for in some instances their reasons for stating that they were more or less dissatisfied with the operation were indefinite However, as the opportunity to make the examinations and observations necessary to refute their statements was lacking, they have been classified as merely relieved The five patients reported as no better were cases in which at operation no definite pathology could be established and the semilunar was removed on insufficient pathologic evidence In the majority of these cases it would have been better to have at least deferred operation Five patients we were unable to trace The internal semilunar cartilages were removed from eight knees at the same time that loose bodies were removed In the majority the loose bodies were the prime cause of the trouble All of these patients reported themselves as completely cured In twenty-four instances, loose bodies were removed from the knee joint when they were considered to be the chief offenders Sixteen patients reported themselves as cured, five were not traced, and three were relieved The latter three cases were those of elderly people who had arthritis associated with the condition Undoubtedly much of their present complaint is due to that

Two cases of rupture of the crucial ligaments were treated conservatively by placing the knee slightly flexed in a plaster of Paris cast Full function was restored

To sum up, fifty-six of the eighty-seven patients operated on for mechanical derangements of the knee due to intrinsic causes were cured, twelve were relieved, five reported themselves as no better, and fourteen were not traced

CONCLUSIONS

1 Damaged semilunar cartilages should be accorded the careful treatment by rest and fixation that is given an ordinary fracture of one of the long bones Recurrent locking will then be an uncommon sequela

2 Recurrent locking produced by a loose or fractured semilunar cartilage or loose body demands removal of the meniscus or body under the strictest asepsis A judicial exploration, of the joint should be made at the same time

3 The condylar incision is the incision of choice for the removal of the semilunar cartilages

4 For the removal of loose bodies, the split-patella incision is usually best

5 A ruptured crucial ligament is better treated conservatively than by operation

ABSTRACT OF DISCUSSION

Dr John Ridlon, Chicago I agree entirely with all that Dr Henderson said, but I would like to say that in injuries of the knee joint in which the semilunar cartilage may have been injured, it is most important to put the leg straight in a plaster cast and keep it there until all symptoms have been absent for a long time If symptoms return without there having been an accident, it is necessary to go into the joint, unless some reason otherwise is shown I think that we are going to find a lot more cases of osteochondritis dissecans than heretofore When I published my paper I reported three cases Before that Dr Freiberg's case was the first, and I think the only one in this country, and my three were the next The cases are not common Dr Henderson has been able to show a number probably because he knew what to look for We have had an unusual case since the publication of my paper A young woman presented the typical Roentgen-ray pictures of osteochondritis dissecans in both knees On opening the right knee we found the cartilage of the inner condyle blistered up, but no loose body In the left knee we found the cartilage in the same condition and a loose body, biscuit-shaped, 1⅛ inch in circumference and one-fourth inch thick. This was removed A year later the Roentgen-ray pictures showed a loose body in the right knee another spot of osteochondritis dissecans in the left knee and another loose body in that joint

Dr J P Lord, Omaha About twelve or fifteen years ago Dr W J Mayo called attention to the advantages of a transverse incision of the knee for extreme infections of the knee joint Having had experience in opening the knee thus freely with very desirable results, and regarding it as not of serious consequence, I used this method of exposure in one case with highly gratifying results in which the patellar tendon was divided and the knee joint widely opened, wh enabled me with great facility to remove the foreign bod

---

[15] Jones R, and Smith S A On Rupture of the Crucial Ligaments of the Knee and on Fractures of the Spine of the Tibia, Brit Jour Surg 1913 1914 1, 70

They were very large and eight in number, one being nearly 2 inches in extent, and of a mulberry type Part of these bodies were well behind the condyles, and it had seemed to me that no other incision would have been adequate to have made an assured success of their removal without, perhaps, more exposure and damage than there was in the very radical procedure of opening the joint in the manner described I do not pretend to say that this is very often indicated

Dr W C Campbell, Memphis, Tenn Dr Henderson stated that he has not removed a single external cartilage during all the series A few days before I left I removed the external cartilage from a man who gave a very interesting history He had three days previously a sudden locking of the knee, which had caught at a greater angle than I had ever seen It was fixed and held at a right angle Six or eight years before, he had had a number of attacks, and then, without treatment, they had stopped, and he has had no trouble for three years He had always before been able to straighten the knee after a few hours This time, however, he was unable to do so He was brought to me with the knee flexed at about a right angle and fixed in that position I insisted on taking him to the hospital and doing an operation to get the leg down, if he could not reduce it otherwise He refused treatment or operation, so he went home and stayed there ten ays Then he came back with no improvement in his con[illegible] There was practically no effusion in the joint when joint was opened The knee was freely movable in flexion yond the point of locking On operation, I found that the external cartilage was so long that it was folded on itself in the joint I removed it by the usual external incision

Dr Robert B Osgood Boston I agree in the main with Dr Henderson, but I think that it is a mistake to consider this semilunar cartilage problem a simple one or to be dogmatic about the operation I understood him to say that we should take three fifths of the cartilage away I am not sure that that dictum is wise because I have seen certain cases in which perhaps three fifths have been removed, and in which the symptoms of slipping did not return, but the symptoms of riding up over the end of the cartilage left did occur, and seemed to be overcome by an operation which secondarily removed the posterior portion of the cartilage More than that cartilages are often found, in my experience, not simply detached in their anterior portion, but sometimes quite extensively detached along their whole border The flopping inward and outward gives rise to the symptoms It would be, in such cases, obviously unwise to remove simply the anterior portion They are sometimes split longitudinally as if cut with a knife from one end to the other I have found this a number of times, the internal, or joint, side being free, and the other side attached to the coronary ligament It would obviously be unwise to remove simply the anterior two thirds in such a case as that These are problems which demand an exposure of the whole site and the condylar incision, which Dr Henderson advises is the best I take him to mean an incision that is longitudinal in its upper portion and then sweeps backward at the level of the joint line At the Massachusetts General Hospital clinic during the last year we have had two cases of external cartilage, as well as internal

Dr Edwin W Ryerson, Chicago Dr Osgood's point about the removal of the whole cartilage is excellent If you are going to remove any, why not take out the whole thing? The operation is easier with the leg flexed at a right angle on the edge of the table Then the leg can be rotated around, so as to reach the posterior end of the cartilage The anterior end can always be removed easily The other end can be snipped off with a pair of strong curved scissors Loose bodies are sometimes extremely annoying If you get into the joint without having first transfixed the loose body you sometimes cannot find it even with a wide opening It is possible to take it out under local anesthesia in most cases In one case in which I was operating under a local anesthetic I could not find the loose body, which was as large as the end of the thumb The man said, "I can find it for you", so we put a pair of sterile rubber gloves on his hands, and in a minute he squeezed out the loose body, which flew on to the floor Another point about the transverse incision is useful Do not make too long an internal incision I saw an incision 7 inches long made by a surgeon in Chicago It is only necessary to make a short incision, the perpendicular part being an inch and a half long, and the transverse part about 2 inches, as described by Robert Jones I want to report another case of external semilunar cartilage fracture caused by a man being struck by the lower step of a train It made a great deal of trouble for the patient until the cartilage was removed

Dr J T Watkins, San Francisco I understood Dr Henderson to say that he would not operate when the rupture of a semilunar cartilage occurred the first time I think it would be right to qualify that statement according to the occupation of the individual For instance, twice during the last year, once in a painter and once in a carpenter, I had to attack the semilunar immediately I felt that I could not send the man up on a scaffolding with the knee in that condition, because a recurrence might mean his death by a fall Mr Jones, in his classical monograph, warns us that we may find all the symptoms at the inner or the outer side of the point only to find at operation that the other was the one involved I had that experience last winter I went in and found that the semilunar on the side where the patient gave all the classical symptoms was as good as any one's, and then discovered that the cartilage of the other side was the torn one

Dr Melvin S Henderson, Rochester, Minn Dr Lord mentioned the transverse incision I have not used it except in resections of the joints, but see no reason why with proper care, avoiding the lateral ligaments, it should not be used in cases such as Dr Lord speaks of Dr Campbell has mentioned the damage to the external semilunar cartilage To me this is very interesting because in our series we have not had such a case It may be that we have overlooked the condition in some of our cases Dr Osgood s criticism is a just one—in the part of the paper I have read I have not mentioned much about the internal semilunar cartilage as I found it necessary to reduce the paper in order to read it in the allotted time Some of the points mentioned by Dr Osgood have been taken up in the fore part of the paper I believe that the removal of the anterior three fifths of the semilunar cartilage in the majority of cases is sufficient Of course, if the fracture is further back it must be removed back of the fracture One reason for advocating this is that a larger incision is necessary to remove the entire cartilage and in using the larger incision one is apt to damage the internal lateral ligaments and it is best to avoid this as much as possible Dr Watkins mentioned not operating the first time the derangement occurred If the reduction cannot be accomplished otherwise, of course, operation is necessary Such a case was that mentioned by Dr Campbell in which he was unable to reduce the dislocation and found it necessary to remove the external semilunar cartilage in order to straighten the leg

Food Values and Appetite—Not all food materials are valuable in proportion to the appeal which they make to the appetite For example, the flavor substances in foods which stimulate the olfactory and gustatory nerves, and thus give rise to appetite, are not ordinarily the substances on which the body depends for its fuel, nor for the great bulk of its building materials The latter materials—proteins, fats or oils, and carbohydrates—when chemically pure, have little or no taste or smell The preference for thin and crisp rather than greasy bacon is an illustration In a recent experiment it was found that of the 129 calories which represented the fuel value of a very thin 20 gm (three-fourths ounce) slice, only nine calories remained when the slice was sent to the table, 120 calories being represented by the fat which "fried out" into the pan In this case a considerable amount of flavor body also goes into the fat, yet most persons would not consider eating it unless it has been skilfully blended with large quantities of other foods, whereas the scrap of skeleton tissue which has lost 93 per cent of its food value is a dainty morsel—Minna C Denton, *Scientific Monthly*, December, 1916

RESULTS OF RESEARCH ON CONDITIONS AFFECTING POSTURE*

HENRY LING TAYLOR, M D
NEW YORK

Much has been said and well said on the importance for health and efficiency of straight standing and sitting, and on the deleterious effect on posture of weakness, poor health, overwork and certain types of physique

The effect of extrinsic conditions, such as clothing, furniture and certain features of family, school and industrial life on habitual posture, are also important In order to study such matters more closely and to improve personal and environmental conditions affecting posture, the American Posture League was organized three years ago by a group of physicians and educators, and this paper aims to present some of the results of work done by its technical committees, or officially approved by them

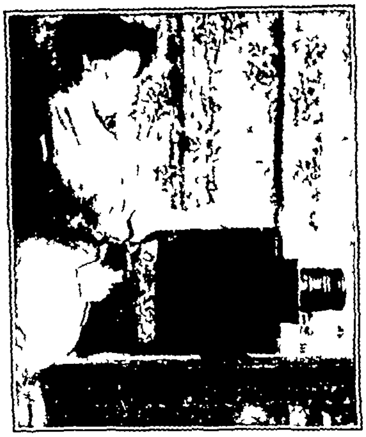

Fig 1 —The Mosher Lesley schematograph

Broadly speaking, a good basic standing posture is one in which the different segments of the body, head, neck, chest, lower trunk and legs are balanced nearly vertically on each other like a column with its base, shaft and capital

The posture of the standing figure may be tested in side view by comparison with a vertical line passing through the ear In order to illustrate good posture and contrast it with a relaxed and with an exaggerated posture, the league has issued two wall charts of a girl and boy, respectively, illustrating the three attitudes in side view These charts have been widely used in class rooms, physicians' offices and families, and have proved their practical value

A new method of recording posture is furnished by the Mosher-Lesley schematograph, a camera-like apparatus which reflects the figure much reduced in size on a horiztontal glass plate over which a sheet of tracing paper is stretched On this the outlines of the figure may be traced in front, side and rear views, if desired, and preserved for record or comparison with subsequent tracings The outline of the figure may also be traced in other postures

The effect of various postures on the position of the internal organs, especially the stomach and colon, has been studied fluoroscopically by one of the league's technical committees, which reported that in normal subjects standing, the fatigue posture, and also the lordosis posture lowered the abdominal organs, the erect posture invariably raised the organs from 1 to 3 inches Breathing with chest up, especially with contraction of the abdominal muscles, raised the organs 1 to 5 or 6 inches Ordinary deep breathing had little effect on the organs The recumbent posture usually elevated the organs from 1 to 4 inches

The conclusions of the league's technical committee on shoes are of general interest, and it seems to us of great importance A preliminary investigation failed to show any exact anatomic basis for the prevailing shapes of lasts, and it was decided that a study to determine whether average feet were of one or several types was necessary before the subject of shoes could be intelligently attacked It was also seen that the ground plan of the foot should be a determining factor in the ground plan of the shoe A call was sent out to the membership of the league for tracings of average feet, with other data, and 1,422 answers were received from various parts of the United States, India and China In order to determine the relation of the front of the foot tracing to the heel, the more stable part, the tracing of the heel was bisected longitudinally and the axis thus found was prolonged to the front of the foot In order to do this conveniently, a simple instrument called a foot meter was devised This consists of a piece of transparent celluloid, 7 by 13½ inches, on which a central line is drawn, with parallel lines at equal distances on either side giving the distance in quarter inches from the central line This central line is so applied to a foot outline as to bisect the heel, when the distances of the outline at the ball from this axis on the outer and inner side may be read off from the foot meter

Studied in this way, the foot tracings were divisible into three types (1) those in which the heel axis prolonged forward divided the ball equally to within less than a quarter of an inch, these were called straight feet In other tracings (2) the larger part of the foot at its widest part fell to the outer side of this axis, these were called outflared feet In still a third class of tracings (3) the larger distance from the heel axis lay to the inner side, these were called inflared feet

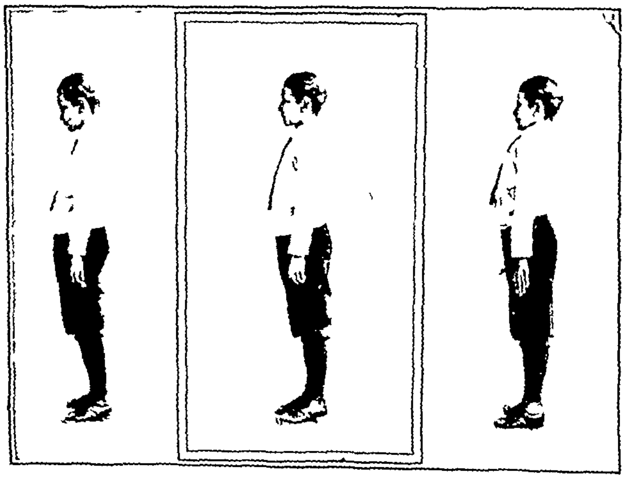

Fig 2 —Standing postures

In 1,131 tracings of American adults, dropping fractions, the following percentages were shown straight feet, 30 per cent , inflared feet, 14 per cent , outflared feet, 56 per cent The percentage did not greatly differ in men and women We have nearly a hundred tracings of American children under 11, but are collecting more, especially of the younger ages, for special study

---

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

One hundred and seventy tracings of the feet of Oriental adults from China and India, many of whom have never worn shoes, showed the three types of straight, outflared and inflared feet as in shoe-wearing Americans, though the percentages of the three classes are different Leaving out fractions, the 170 were divided as follows straight feet, 36 per cent , inflared feet, 38 per cent , outflared feet, 26 per cent

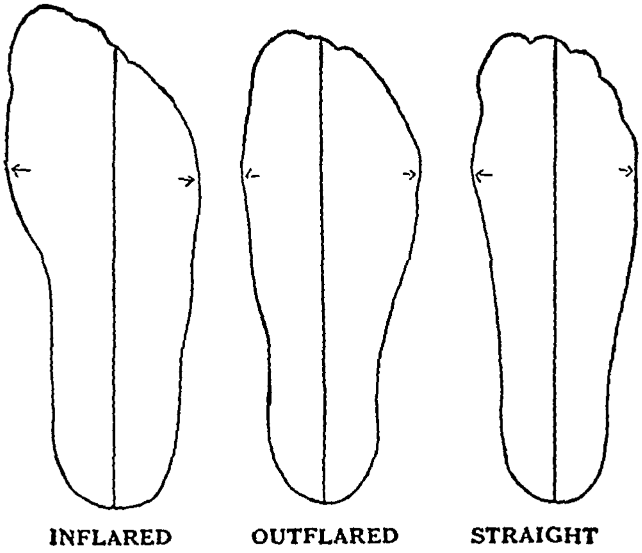

Fig 3—The three types of feet established by studies of the American Posture League

A further study of these tracings, especially as to the effects of barefootedness and laborious occupations on the type, is now in progress Since the ground plan of the foot may be straight, inflared, or outflared, it follows that no one type of shoe will fit all feet Shoes are now being constructed over lasts of the three types, designed by a technical committee of the American Posture League, and will soon be on the market These shoes not only have been designed with reference to the anatomy of the foot, but also have been made as light and attractive as was compatible with their intended use

Other technical committees have laid down principles and effected reforms in the construction of ready made coats, and in garment suspension It was found that many ready made coats for men and boys were too narrow in front and too loose behind because made over a round-back model Such coats virtually compel poor posture This was taken up with a large manufacturer, and the coats were remodeled to proper shape

The weight of garments should be suspended from the shoulders near the neck, and from the pelvis above the hips, the shoulder tips and waist should not bear the weight of clothing Waists and garters have been designed on these principles

The Furniture Committee, having no apposite anatomic data, sent out a questionnaire to members on certain measurements of the adult clothed figure, and based its work on chairs and seats on a study of these measurements and other experimental data In hygienic seating the feet, thighs, pelvis and spine are comfortably supported in proper relation to each other Pressure on the popliteal region, and outer part of the scapulae and shoulders is avoided Support to the back is given mainly in the upper sacral region, and lower half of the dorsal region The chair floor is shaped to distribute pressure, and to prevent the pelvis sliding forward A large space is provided at the lower part of the chair back, so that the buttocks may not be pushed forward The chair back should be flat from side to side, or only slightly hollowed, so that the shoulders and scapulae may not be pushed forward The slope of the back and other features vary with the use for which the seat is designed, the back being more reclined in chairs designed for resting

Seats have been worked out for the new subway cars of the Brooklyn Rapid Transit Company and are now in use A standard movable school chair and desk have been remodeled and have given great satisfaction in use Kindergarten and vocational chairs have been designed, and several models of office chairs have been remodeled on scientific lines A child's seat for baby-carriage and automobile has been designed from anatomic measurements

Reading, writing and drawing on a flat surface exert a pernicious influence on posture and often produce eye strain When the book or drawing board is held at a moderate slope from the vertical, the easel position, the posture is improved and eye strain relieved An adjustable book rest has been devised, which holds the book or drawing board at the angle of choice and at the proper height

A design for a sloped library table for reading has just been sent in for the league's inspection Such tables have been in successful use in the children's department of the Cleveland Public Library

Much information and material tending to greater comfort and convenience and the betterment of posture conditions are being continually presented for the consideration of the league, which acts as a clearing house for all such matters Material officially approved bears the league's label

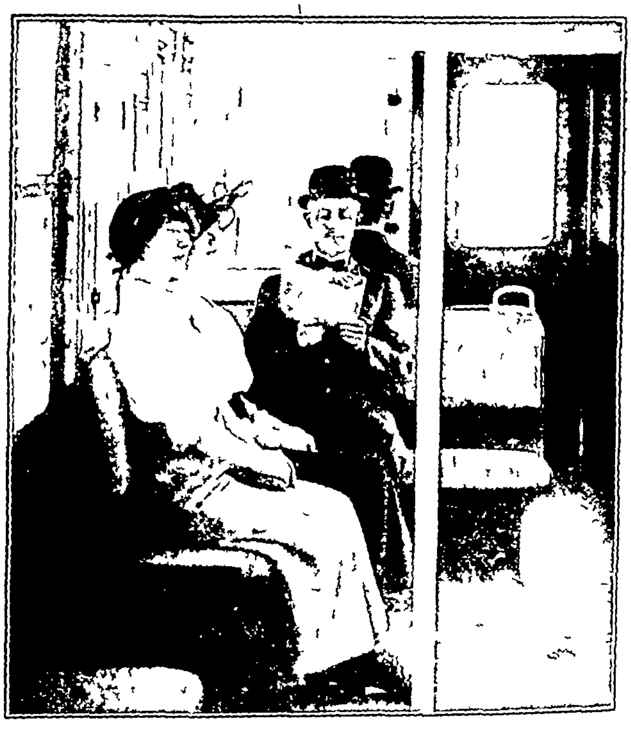

Fig 4—Anatomic subway car seat

The foregoing is a very brief summary of a few of the things actually accomplished by the different technical committees, and the interest and scope of the work are constantly increasing

The scientific standardizing of wearing apparel, furniture and the various appliances used by the worker makes a special appeal to the orthopedic surgeon, but should also interest the practicing physician and the general public

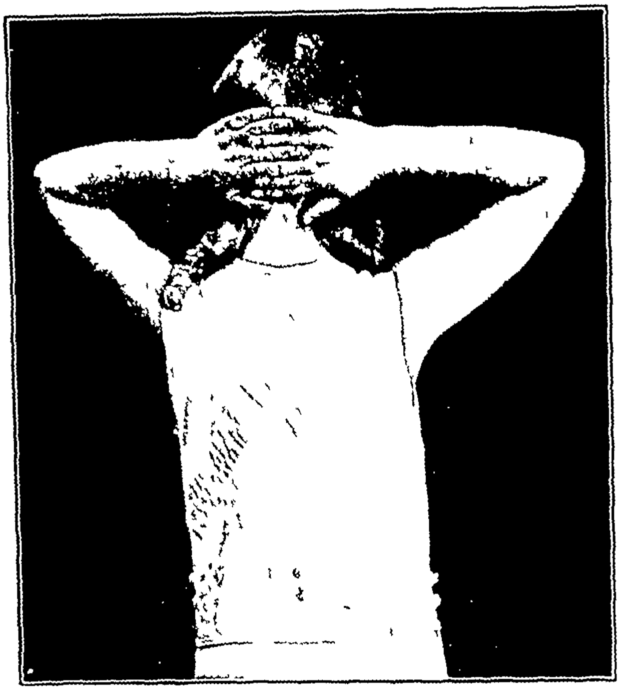

Fig 5—The rest right waist

The league's scientific exhibit at this meeting shows the scope and quality of the work already done better than any description The cooperation of all in this work whose benefits are shared by all is cordially invited

125 West Fifty-Eighth Street

ABSTRACT OF DISCUSSION

Dr Joel E Goldthwait, Boston To mold the human body is important if we are to develop the best efficiency of the individual If we allow the increasing number of slender individuals to grow up as they are, we shall have an increasing number of men and women to stand as the figure that Dr Taylor showed You can see hundreds of them No one needs to be a physician to glance at such a figure and know that it is not a healthy body and not an efficient creature If we are to treat these people we must appreciate the different anatomic forms that make it possible for one person to have one type of back, and another person another, and we must try to find out the cause of the difficulty from which each suffers If we think of our patients in that way we can do much to help them We can visit factories where people are employed, we can show them how to arrange things better Not only should we see that proper seats are provided, but we should also see that the people using them understand how to adjust them properly themselves Then there would be less backache and pulmonary disease, which must come primarily from the fact that the body is so used that the parts cannot work without strain

Dr Malcolm C Rose New York For a number of years I have taken the simple precaution of asking people to take two minutes' exercise night and morning in their bedroom, without clothing The object of not having clothing on is to give freedom of movement and that they may see how they are holding their body Tell them to put their knees back it will bring out the center of the chest, tell them to take two minutes' exercise in the room, and they will tell you within a short time how they have improved in general feeling the way they carry themselves

Dr Eliza M Mosher, Brooklyn, N, Y The relation of habits of posture to health is much more intimate than is usually supposed Two bad habits of posture are the "sidewise slouch" and the "heel postures" We all recognize the importance of free rib movement, especially that which maintains a constant interchange of gases at the apexes of the lungs The fact has been established that tuberculosis usually begins at the apex of the lung in which from any cause there is lowered movement of tidal air during the daily activities of life The "sidewise slouch' posture can easily be shown to be one that mechanically limits rib movement on one side of the chest, especially in its upper part It happens in this wise the lax everted leg, instead of a support, becomes a weight which drags the pelvis down lowering of the hip on one side means a proportional elevation of the opposite hip This change in the pedestal of the trunk would unbalance the body if other weights were not moved over to enable it to regain its equilibrium The weights moved are the shoulder and arm of the opposite side and generally the head In doing this the spine assumes a long lateral curve with its convexity toward the high hip and low shoulder These changes in the shape of the bony skeleton necessarily cause approximation of the ribs on the side of the supporting leg—which is almost invariably the right, and separates the ribs on the side of the low hip and elevated shoulder With ribs thus posturally separated the inspiratory muscles are helpless (to raise them) as also are the muscles of expiration to draw them down Hence the movement of tidal air is inhibited more or less completely In an examination of a large number of tuberculous patients I have almost invariably found the "slouch" habit of posture present and the disease beginning on the side of the low hip and high shoulder While the so-called 'heel posture" produces round shoulders and flat chest it does not greatly interfere with the movement of air in the chest Its malign influence is exerted on the abdomen and its contents The shutting down of the ribs on the upper abdomen shortens the distance between sternum and pubis, thus lessening the activity of the abdominal muscles and crowding the viscera downward This usually produces enteroptosis sooner or later with the setting free of its fateful brood to injure the body in all its parts The American Posture League bespeaks the cooperation of all physicians in its efforts to correct and standardize the things in our environment that tend to produce incorrect habits of posture and to measurably improve public health thereby

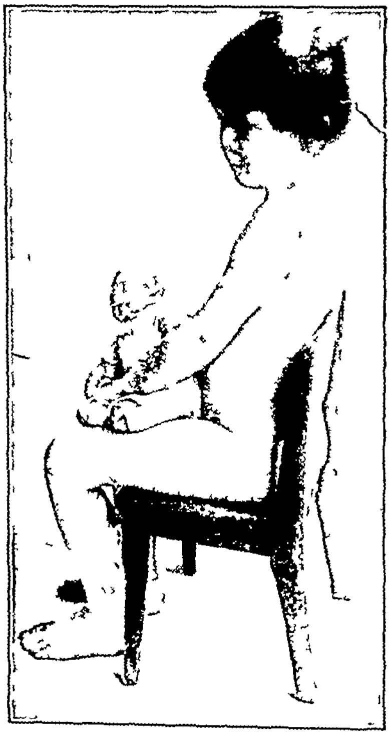

Fig 6—Anatomic kindergarten chair

Dr E S Everhard Dayton, Ohio What constitutes correct posture has been largely a matter of individual opinion Each orthopedic surgeon, each director of physical culture and each general practitioner interested in it has his own idea In the correct posture a line through the head and neck in front of the ear is vertical, one from the middle of the shoulder down through the trunk is vertical, and one from the middle of the trunk through the legs is vertical This is known as the vertical line test for posture It is valuable because it gives a standard There are three types of feet, the "inflared," the "outflared" and the straight If we put an "inflared" foot into an "outflared" shoe, we cannot expect good results

Dr Roland Meisenbach, *Buffalo* To establish the correct posture is by no means a simple problem The work of establishing correct attitude, as Dr Taylor is doing, is certainly commendable Faulty attitude, like ptosis, cannot be corrected dogmatically There are several reasons for this In the first place, the variation in the anatomy of individuals must be taken into consideration, also the frequent occurrence of disease, as, for instance, rickets, especially in children, must be considered, likewise the flat back and the lordotic back In regard to the sitting posture, I believe the time will come when we will have to conform our chairs to the individual rather than the individual to the chair This is especially true in schools, and in special schools

Dr S A Knopf, New York People who are subject to tuberculosis should not only be taught how to walk straight but how to breathe properly and deeply I should like to see children enabled to sit comfortably, particularly in schools, on properly adjusted seats and at desks of the right height, and above all, *they should not be obliged to sit quietly* without moving for too long a time It is an awful task for a youngster to sit for three quarters of an hour without wriggling It is very sad to see so many children become subject to tuberculosis who have no tendency either by heredity or by reason of early infection but because they have been confined altogether too long in badly aired and often overheated schoolrooms and obliged to sit in an unnatural posture and with but a few minutes' recess and often only in a dusty indoor playroom Let it be understood that no matter how good the posture, if it is maintained too long without change and the air is not fresh good and pure, it cannot be productive of good To still further develop good, sound lungs and increase the vigor of the children, I would like to see singing recitation, botany and geology taught out of doors as much as possible I firmly believe that in this way you can do much to diminish tuberculosis in childhood A recent study on the period of life at which infection from tuberculosis takes place most frequently has convinced me more than ever that if we wish to combat tuberculosis successfully we must begin to prevent and cure it during childhood If we do this at the right time, at the right place, and in the proper manner, we cannot fail to be successful

Dr Henry Ling Taylor, New York This is merely one aspect of the great movement for better hygiene I am quite in sympathy with what Dr Knopf said School hygiene and industrial hygiene are both in great need of reformation, but we cannot expect, by simply giving an employee a good chair, to effect a hygienic reformation in him, when he is, perhaps, underfed and underpaid

---

Appendicitis in Prussia—The *Medizinische Klinik* gives the statistics in regard to *Blinddarmerkrankungen in Prussia* during 1913 While in 1912 there were 1,888 deaths from *Blinddarmentzundungen* in the various medical institutions, in 1913 the number was 2,185 Operative treatment was applied in 63 99 per cent and 5 11 per cent of the patients died The mortality was only 3 47 per cent among the women, and 5 61 per cent among the men, but the mortality in the operative cases was 6 69 per cent among the men and 3 86 per cent of the women About 56 per cent of all the cases occurred in persons between the ages of 15 and 30 The mortality was highest in the elderly, 130 died of the 390 elderly patients given operative treatment, out of a total of 664 elderly patients

CONTRIBUTIONS TO THE PHYSIOLOGY OF THE STOMACH

XXXVIII GASTRIC JUICE IN DUODENAL AND GASTRIC ULCERS *

LESTER R DRAGSTEDT, M S
CHICAGO

The present work was undertaken to learn the effect of gastric juice on the rate of healing of acute gastric and duodenal ulcers It is well known that lesions of the gastric and duodenal mucosa heal readily in the presence of active gastric juice Small abrasions of the stomach mucosa, such as those following at times the administration of a stomach tube, are common, occasion no discomfort to the individual, and in a majority of cases heal without further sequelae Surgical operations in which there is a maximum insult to the mucosa cells are not commonly followed by untoward effects due to the digestive activity of the gastric juice

Nevertheless, up to the present, the medical and surgical treatment of gastric and duodenal ulcers has been based essentially on the theory that the gastric juice induces chronicity of these ulcers by digesting the exposed edges of the mucosa This is a point of great practical as well as of theoretical importance If pepsin—hydrochloric acid—has so great a digestive action on the injured mucosa that it maintains ulcers for months and even years, this fact ought to be readily demonstrated in well controlled laboratory experiments, where one can eliminate most, if not all, of the undetermined factors that unfortunately complicate results on patients

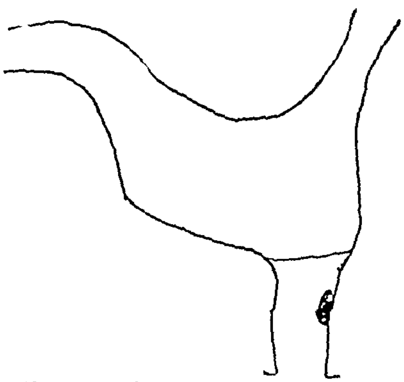

Fig 1 —Pawlow pouch arranged to secure maximum drainage of gastric juice

The clinical and experimental literature with reference to the role of gastric juice in the healing of ulcers is vast and conflicting Sippy[1] states that under medical treatment consisting of rest in bed and the feeding of alkalies and highly nutritious foods at frequent intervals, the healing of gastric and duodenal ulcers is markedly accelerated Here it is not evident that the neutralization of the gastric juice is the important factor, as, according to some authorities (Osler[2]), a treatment consisting solely of rest in bed and easily digested foods gives favorable results Inaccurate diagnosis is at least one important factor in explaining the apparent cures of gastric and duodenal ulcers under medical treatment In 264 cases of gastric ulcer operatively demonstrated at the Mayo Clinic, 1913-1914, there was an error in the primary diagnosis in 33 per cent There was an equally high percentage of error in 814 cases of duodenal ulcer[3] These cases were severe enough to indicate surgical intervention, and in such cases the diagnosis is more accurate than in the less severe forms

The good results, reported after gastro-enterostomy for pyloric duodenal ulcers, must be carefully scrutinized in view of the work recently reported by Boas[4] Examination will frequently reveal occult blood in patients apparently cured by the operation, in whom there is absence of pain and other subjective symptoms As suggested by Carlson, the relief from pain following the administration of alkalies or following gastro-enterostomy may be due to other factors than the effect on the gastric juice Burge[5] regards the digestive action of the gastric juice together with decreased resistance or oxidative properties of the mucosa cells as the causative agents in gastric ulcers Bolton[6] gives a number of experiments in which artificially produced hyperacidity delayed the healing of experimental ulcers in rabbits The degree of acidity employed by Bolton is far in excess of that found normally in the rabbit, and from the work of Hardt[7] and others there is considerable doubt whether there is an actual hyperacidity in cases of gastric or duodenal ulcer The experiments of Friedman and Hamburger[8] are not very conclusive on this point Their results indicate pyloric stenosis with consequent food retention in the stomach and hypersecretion of gastric juice as the important factors in the delayed healing of gastric ulcer So many others factors are involved in their experiments that the effect of the gastric juice alone in determining the chronicity of ulcers is not evident E C Rosenow[9] has produced acute and chronic ulcers in the stomach of dogs by the injection of certain strains of streptococci, obtained from the depth of gastric ulcers in man He has also shown that gastric and duodenal ulcers in man are usually infected, that the route of infection is by way of the blood stream, and that the primary focus of infection may be in some distant part of the body The importance of the difference in virulence of different species and strains of bacteria and the possibility of reinfection from the primary focus, as important factors in determining the chronicity of ulcers, have not been sufficiently considered No work accurately controlled has as yet been reported showing the relative rates of healing of acute lesions in the stomach and duodenum both in the presence and in the absence of active gastric juice

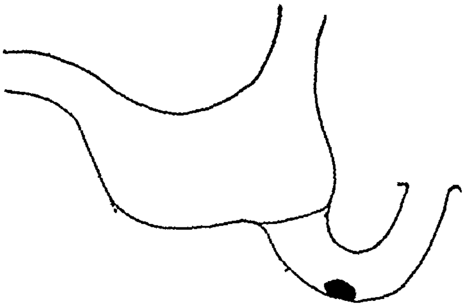

Fig 2 —Pawlow pouch arranged to secure retention of gastric juice in the pouch

EXPERIMENTAL PROCEDURE

1 *Preparation of Experimental Animals* —Healthy dogs were selected for the experiments and were prepared according to the following technic In one series of four dogs, the regular Pawlow operation, for producing a second small stomach, was done and the pouch brought to the surface through the left rectus muscle In this case the axis of the pouch was perpendicular and there was an optimum condition for drainage of the gastric juice secreted in the small stomach (Fig 1) In another series of four dogs the Pawlow operation was performed, but in this case the pouch was brought to the surface high up on the left side just below the costal margin (Fig 2) Here the outlet was the highest part of the pouch, and, as a result, the gastric juice secreted could not escape until the small stomach was full Two other factors were instrumental in keeping the pouches of the second series of dogs at all times full of gastric juice Owing to the formation of scar tissue about the fistula and subsequent contraction, a functional valve was formed in several cases In all of the dogs of this series, the irritation of the juice on the skin about the fistula was considerable and the animals could nearly always be found lying on the right side Examination in these cases always showed the pouches full of juice and at times under a little pressure In both series of dogs, the gastric juice was tested for acidity and pepsin strength

For the experiments on the rate of healing of acute duodenal ulcers in the absence of gastric juice, dogs were prepared in the following manner The pylorus was excised, the pyloric end of the stomach infolded and closed, and the upper part of the duodenum closed Posterior gastro-enterostomy was then performed In this case it is fair to assume that the upper blind end of the duodenum was free from acid chyme at all times Whatever chyme regurgitated into the duodenum from the gastro-enterostomy opening would be neutralized by the alkaline bile and pancreatic juice, and the duodenal peristalsis incited would carry the neutralized chyme back to the jejunum To obtain data on the rate of healing of duodenal ulcers in the presence of gastric juice, normal dogs were used

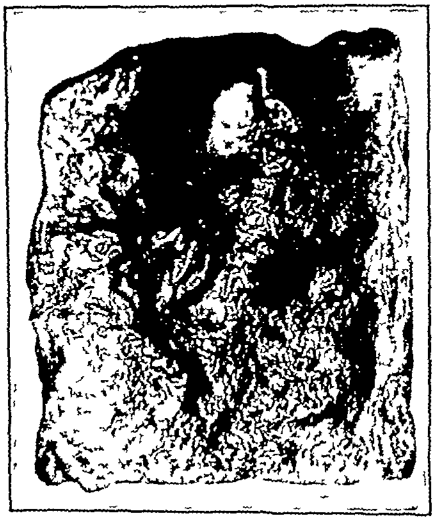

Fig 3 (Dog 38 Table 4) —Ulcer in the duodenum (fifteen days) not exposed to the action of gastric juice

2 *Production of Ulcers* —Local injection of a 5 per cent solution of silver nitrate was chosen as the surest method of producing ulcers The technic employed was similar to that of Friedman and Hamburger[8] For the production of ulcers in the Pawlow

pouches, 1 5 c c of a 5 per cent solution of silver nitrate was injected through the mucosa into the submucosa of the wall of the small stomach A syringe with a long hypodermic needle was used for the operation, and the fistula was held open with a small rectal speculum The injection of silver nitrate produced a local necrosis of the mucosa, the necrotic material sloughing off in a few days, leaving an acute ulcer

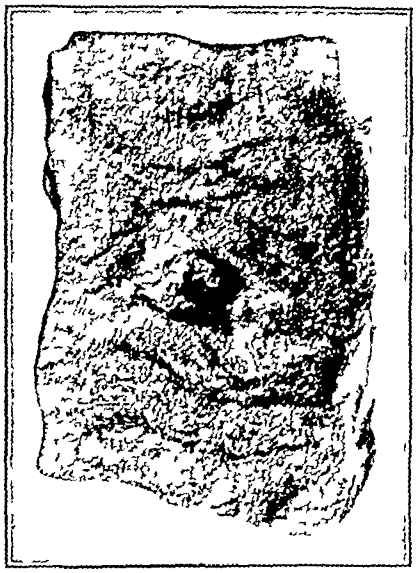

Fig 4 (Dog 40 Table 3) —Ulcer in the duodenum (fifteen days) exposed to the action of gastric juice

In the work on the duodenum, the technic was as follows In the normal animals a laparatomy incision was made through the right rectus, and the duodenum secured, and lifted out through the incision An injection of 1 5 c c of a 5 per cent solution of silver nitrate was made through the serosa and muscularis into the submucosa of the intestine A similar procedure was observed in the other series of animals, after allowing ten days for the healing of the operation for gastro-enterostomy and pylorectomy

TABLE 1—EXPERIMENTS TO DETERMINE THE LENGTH OF TIME REQUIRED FOR THE HEALING OF ULCERS IN THE PAWLOW POUCHES ARRANGED FOR OPTIMUM DRAINAGE OF GASTRIC JUICE OR IN ABSENCE OF GASTRIC JUICE

No of Dog	Number of Experiment	Number Days for Complete Healing of Ulcer	Acidity of Gastric Juice					
			Maximum		Minimum		Average	
			Free	Total	Free	Total	Free	Total
2	1	9	0 000	0 1550	0 000	0 0912	0 000	0 0912
2	2	15	0 000	0 1641	0 000	0 0912	0 000	0 0312
4	1	7	0 1915	0 2827	0 000	0 036	0 000	0 1276
4	2	8	0 1824	0 2730	0 000	0 0819	0 000	0 1094
4	3	10	0 2006	0 2918	0 000	0 036	0 000	0 1185
6	1	8	0 0912	0 1003	0 000	0 056	0 000	0 045
8	1	9	0 1003	0 2371	0 000	0 054	0 0912	0 1094

Average time for healing of ulcers is nine days

In both the work on the stomach and duodenum special effort was made to produce ulcers of the same size in all cases The needle was inserted into the submucosa and the same amount of silver nitrate was always injected The silver nitrate produces an immediate coagulation necrosis of the tissue which is visible as a white or gray area about the point of injection With this as a guide, the same amount of tissue destruction would be produced in every case

RESULTS

The results in brief are as follows

1 The average time required for the healing of the experimental ulcers in the Pawlow pouch, arranged so that there was at all times a quantity of active gastric juice in the pouch (Fig 2), was eight days (Table 2)

2 The average time required for the healing of the ulcers in the pouches, in which there was a maximum drainage for the gastric juice (Fig 1), was nine days (Table 1)

3 The average time required for the healing of the experimental ulcers in the duodenum, both in the presence and in the absence of acid chyme, was twenty days (Tables 3 and 4, and Figs 5 and 6)

TABLE 2—EXPERIMENTS TO DETERMINE THE TIME REQUIRED FOR HEALING OF ULCERS IN PAWLOW POUCHES IN THE PRESENCE OF GASTRIC JUICE

9	1	8	0 1003	0 1915	0 000	0 1094	0 0912	0 1459

Average time for healing of ulcers is eight days

4 Animals, killed and examined at necropsy before the ulcers in the duodenum were completely healed, showed ulcers in practically the same stage of healing in both cases (Figs 3 and 4)

5 Bacteriologic examination of the ulcers in five of the dogs showed a hemolytic streptococcus in pure culture in two cases, mixed staphylococcus and streptococcus in one case, *B coli* in one case, and *B subtilis* in one case The examination was made with the technic of Dr E C Rosenow[9]

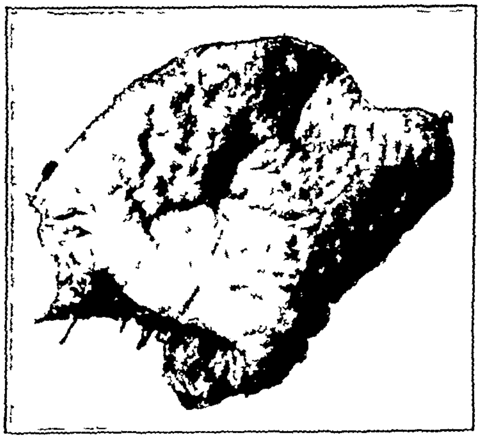

Fig 5 (Dog 16 Table 4) —Ulcer in the duodenum (twenty two days) not exposed to the action of gastric juice

COMMENT

From the experimental evidence obtained, it would seem that the digestive action of the gastric juice is not the important factor in the delayed healing of acute lesions of the stomach and duodenum, and the consequent production of chronic ulcers Acute lesions of the mucosa of the stomach and duodenum do not require any longer time for healing, or display any more tendencies toward chronicity when exposed to gastric juice of normal acidity and pepsin strength, than do similar lesions in the absence of gastric juice

Gastric and duodenal ulcers are, therefore, locally infected areas of the wall of the digestive tract, irrespective of whether the ulcers themselves are produced by primary infection from the blood stream (Rosenow), by local circulatory disturbances, or by mechanical and chemical factors acting on the mucosa

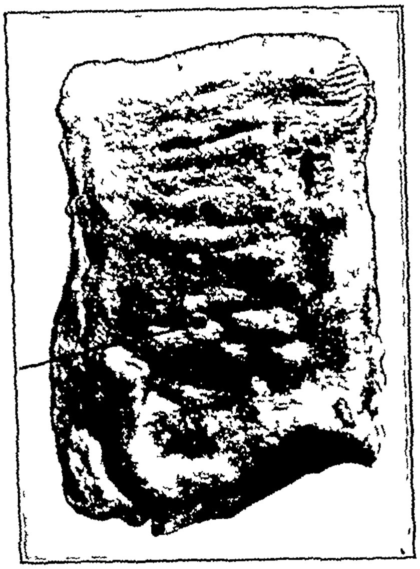

Fig 6 (Dog 32 Table 3)—Ulcer in the duodenum (twenty days) exposed to the action of gastric juice

from the lumen of the intestine It is well known that the tissues surrounding the ulcers are hyperemic It is highly probable that in these hyperemic ulcer areas the nerves (sensory and motor) become hyperexcitable, as is the case in all other areas of infection These hyperexcitable gastric nerves, subjected to stimulation by the normal gastric juice, may thus yield exaggerated responses (motor, inhibitory, and conscious) Carlson suggests that the favorable results from the alkaline and frequent feeding treatments in these cases may be due to the removal of this added stimulation of the hyperexcitable nerves rather than the prevention of any digestive or corrosive action of the pepsin hydrochloric acid on the exposed tissues The degree of reflex disturbance from the acid stimulation of the nerves in the ulcer areas would vary with the individual, depending on the severity and extent of the infection, as well as on the individual stability of the entire nervous organization We should expect it to be much greater in man than in the lower animals

TABLE 3—EXPERIMENTS TO DETERMINE THE TIME REQUIRED FOR THE HEALING OF ULCERS IN THE DOUDENUM IN THE PRESENCE OF GASTRIC JUICE

No of Dog	No Days Since Production of Ulcer	Stage in Healing of Ulcer
37	10	Active ulcer no healing
1	13	Active ulcer 1 5 by 1 cm no healing
40	15	Active ulcer 1 by 1 5 cm no healing
32	20	Ulcer almost healed
33	20	Ulcer completely healed
34	26	Ulcer healed
2	31	Small depressed area in mucosa
22	45	Completely healed

The bacteriologic examination of the ulcers is interesting in that it shows that lesions, produced experimentally by chemical means, may subsequently become infected The bacteria are the same as those isolated from clinical ulcers in man It seems probable that the infection is direct from the alimentary tract, since it is not likely that these bacteria would be found in the circulating blood of otherwise healthy dogs

TABLE 4—EXPERIMENTS TO DETERMINE THE TIME REQUIRED FOR THE HEALING OF ULCERS IN THE DUODENUM IN THE ABSENCE OF GASTRIC JUICE

No of Dog	No Days Since Production of Ulcer	Stage of Healing of Ulcer
36	5	Perforation
35	7	Active ulcer, no healing
27	9	Active ulcer, 0 5 by 1 cm, no healing
11	9	Active ulcer 1 5 cm dia, no healing
25	10	Active ulcer 1 cm dia no healing
38	15	Active ulcer, edges raised indurated
16	22	Ulcer 0 5 cm dia edges indurated
8	24	Ulcer nearly healed one small depressed area
39	27	Ulcer healed
20	32	Ulcer healed
14	30	Ulcer healed

CONCLUSIONS

1 The digestive activity of gastric juice is not the important factor in the delayed healing of acute ulcers of the stomach and duodenum and the consequent formation of chronic ulcers

2 Ulcers produced by local injection of solutions of silver nitrate become subsequently infected with organisms probably from the alimentary tract

THE IMPORTANCE OF AURAL SYMPTOMS IN THE EARLY DIAGNOSIS OF TUMOR OF THE CEREBELLOPONTILE ANGLE *

WELLS P EAGLETON, M D
NEWARK, N J

The eighth nerve, comprising the auditory and the vestibular, from a diagnostic surgical standpoint, may be divided into three portions the *peripheral,* comprising the end organs in the labyrinth, the *intradural,* extending from the fundus of the internal auditory meatus to its entrance in the groove between the pons and the medulla, and the *intracerebral* ramifications of its tracts in the brain to its cortical centers in the temporosphenoidal lobe and cerebellum

The sudden and commanding character of the symptoms in inflammation of the cochlea and semicircular canal are due largely to the small, inelastic walls of the containing bony labyrinth, compelling an immediate paralysis of the function of the delicate nerve structures, their bony case not allowing the gradual development of symptoms from slow increasing pressure on the nervous structure, which frequently occurs in nervous tissue elsewhere (The greater resistance of the auditory portion in the labyrinth in serous labyrinthitis with the preservation of hearing after the complete abolition of the vestibular function is, however, somewhat of this nature)

---

* Read before the Section on Laryngology Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

After the entrance of the eighth nerve into the pons, its proximity to other vital centers generally causes the aural symptoms to be immediately overshadowed The diagnostic symptomatology of lesions involving the intracerebral portion of the auditory nerve is but rarely recognized, although in my experience such lesions are far from uncommon [1]

In the passage of the eighth nerve, through the small space from the fundus of the internal auditory meatus to the medulla, across the posterior border of the middle peduncle of the cerebellum, the nerve, while intradural, is still extracerebral, and, being in a free space, may escape for a long time a paralyzing pressure from a tumor of the cerebellopontile angle

Many cerebellopontile angle tumors, especially dural endothelioma and neurinoma,[2] are of very slow growth, and disturbances of hearing and of the vestibular apparatus of the affected side are frequently the only symptoms of which the patient complains, the aural often preceding other symptoms for months, and sometimes for years [3] On the recognition of the intracranial origin of the aural symptoms may depend the success of surgical intervention, and the reputation of the aurist I know of many instances in which, after weeks and months of unsuccessful inflammations and local treatments, the development of a papilledema has first called attention to the true cause of the deafness (Fig 1)

In studying the aural symptoms of cerebellopontile angle tumors, it should be remembered that they are but a modification of the acute aural manifestations so frequent in fracture of the base of the skull, extending through the petrous portion of the temporal bone The end-result of compression of the eighth nerve, whether from fracture or tumor, is the same, namely, loss of function, deafness and loss of vestibular reactability However, in one, the function of the vestibular apparatus of one side is suddenly upset, but, *in tumor, the slow pressure on the nerve allows of a readjustment of the vestibular apparatus during the process of compression*

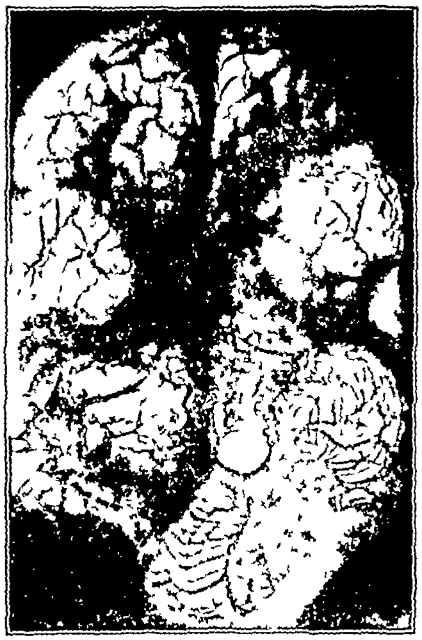

Fig 1—Large endothelioma springing from dura causing great compression of cerebellum Aural symptoms were present for years prior to general symptoms of tumor

In fracture there are suddenly (1) tinnitus and deafness, (2) loss of vestibular reactability, associated with (3) vertigo, (4) spontaneous nystagmus away from the affected side, and (5) spontaneous pointing deviations of both homolateral and contralateral extremities toward the side of the lesion The deafness and loss of vestibular reactability are permanent, but the nystagmus, dizziness, and spontaneous pointing deviations rapidly disappear The transient vestibular manifestations, the dizziness, nystagmus and spontaneous pointing deviations result from a total, sudden loss of function of the vestibular apparatus of the affected side, and the early abolition of these symptoms is due to a readjustment of the vestibular system, as a whole, to meet the changed condition

It is through *the same* readjustment in the vestibular apparatus (*of the opposite as well as the affected side*) which, in the acute cases, so early abolishes the spontaneous nystagmus, pointing deviations and dizziness, that the slowly growing cerebellopontile angle tumors may first manifest themselves

We have at our command for the early diagnosis of intracranial disturbances of the eighth nerve (1) functional examination of the auditory portion, and (2) functional examination of the vestibular portion

So important is a complete and systematic routine functional examination of the eighth nerve, that all patients presenting themselves with disturbance of the hearing or disturbance of the equilibrium should, because of the time consumed and the part played by the personal equation, be delegated for examination to a specially trained attendant

This routine examination by an attendant in my office consists, for the auditory portion, in ascertaining (1) the hearing distance of the (*a*) watch, (*b*) whisper, and (*c*) voice, (2) the lower and upper tone limits and the measuring of their respective durations, (3) the Rinne-positive or negative, (4) reference of the Weber at both vertex and teeth, and (5) the measurement of the duration of the bone conduction

The routine examination of the vestibular apparatus consists of ascertaining (1) the presence or absence of spontaneous nystagmus If from the above I suspect labyrinthitis or intracranial involvement, the attendant further (2) examines the spontaneous pointing of both arms and legs, and (3) explains to the patient the caloric test (*a*) its inconveniences, such as vertigo, possible nausea and vomiting, (*b*) the short duration, during induced nystagmus, of the pointing deviation and falling, and (*c*) its successful application, largely depending on the patient resisting the natural tendency to close the eyes (*d*) The attendant then proceeds to the repeated rehearsing with the patient of the pointing and falling positions

When the patient thoroughly understands what is required of him (4) the cold caloric test is applied in my presence, and during it are noted (*a*) the induced nystagmus, (*b*) the rapidity of its induction, (*c*) whether it is associated with vertigo or a sensation of dizziness, (*d*) the pointing deviation for both arms and legs during the induced nystagmus, and (*e*) the falling tendency

If the patient has been thoroughly drilled by the attendant prior to the application of the caloric (cold) test, it is remarkable what a small amount of time is consumed in making the test, and how much can be ascertained in the few seconds of an induced nystagmus

[3] Wimmer Six Cases of Acoustic Nerve Tumors with Operation, Hospitalstidende, September, 1914, p 1169 Schmiegelow Ztschr f Ohrenh, July 1915

In cerebellopontile angle tumors growing from the dura, endothelioma, or attached to the acoustic nerve, neurinoma or fibroma molluscum, one of the first symptoms complained of is a slight deafness with a distressing tinnitus Routine examination with the tuning forks may make an early diagnosis of an intracranial origin by (1) a reduction of the duration of the bone conduction of the affected side, (2) the referring of Weber to the unaffected side, (3) a positive Rinne on the affected side, and (4) frequently greater alteration of the tuning fork reactions than is accounted for by the amount of the loss of hearing[4]

All these are too well known to be discussed In the vestibular apparatus, however, many problems are still in the realm of speculation

Spontaneous nystagmus is generally associated with tumor of the cerebellopontile angle when the tumor causes compression of the cerebellar cortex, but its slow growth frequently allows of considerable displacement of the cerebellum without nystagmus, in fact, the slowly progressive deafness has, as a rule, long passed into total deafness before the development of nystagmus, by which time a papilledema from increased intracranial pressure may have also appeared Spontaneous nystagmus is apt to be a late manifestation of tumor originating in the cerebellopontile angle, in contradistinction to tumors growing into it from the cerebellum[5] Spontaneous nystagmus is also present in a certain proportion of tumors situated in the cerebrum,[6] in which case, however, there will be no disturbance of the auditory apparatus, the hearing and the tuning fork reactions being normal

Again, in intracerebellar growths, glioma, not involving the cerebellar cortex, spontaneous nystagmus may be entirely absent, although the growth may have attained considerable size, but in these also the tuning fork reactions are apt to be normal, deafness not usually being present

Spontaneous Pointing Deviations — Spontaneous deviations are, in my experience, very rare during all stages of cerebellopontile angle tumors or intracerebellar lesions of slow development, in contrast to their presence in the early stages of acute lesions, fractures and abscesses Especially in those cases not associated with a spontaneous nystagmus are spontaneous deviations uncommon In cases associated with nystagmus, slight deviations from the normal are frequently present, but the deviations are very irregular and variable in their appearance, my experience confirming Grey's[7] observations

Pointing Deviations During Induced Nystagm from Cold Caloric —In cerebellar abscess during a induced nystagmus, there is frequently an absence i the normal pointing deviation of the homolateral si but in cerebellar growths, deviations are variable believe that in small tumors (especially those confine to the auditory nerve, as in a case observed by me o fibroma molluscum, causing complete deafness, and three years later involving the opposite ear) no alteration from the normal pointing deviations will be present In the larger growths of the angle and those originating in the cerebellum and growing into the angle, the interference with the normal pointing deviations will depend on the tumor being extensive enough to interfere permanently with the functioning of the cerebellar cortex or tracts of the different parts

In increased intracranial pressure from disturbances of the cerebrospinal fluid system, variations in the degree of increase may cause variable pointing deviations, the latter being at one time absent and at another time present (Fig 2)

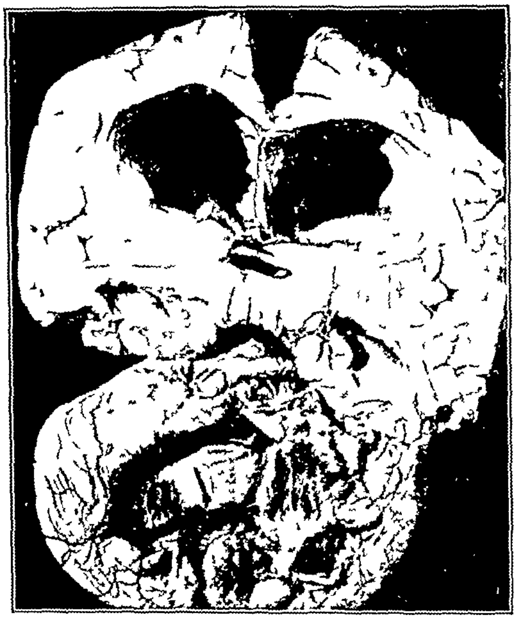

Fig 2 —Small tumor with large secondary cyst of cerebellum causing great hydrocephalus During life, spontaneous nystagmus was absent Vestibular reactability was at times present and again absent

Vestibular Reactability of the Unaffected Side —The diagnostic assistance obtained from the cold caloric of the ear on the opposite side to the lesion has been of the greatest value in the cerebellopontile angle tumor In cases of partial deafness of one ear, cold caloric applied to the unaffected ear uniformly gave a *greatly diminished reactability*[8]

After the deafness has become complete and symptoms of increased intracranial pressure, such as a papilledema, present themselves in my experience, it is frequently impossible to induce nystagmus by the syringing of cold water into the ear of the unaffected side, and if a slight nystagmus is induced, it is unaccompanied by vertigo or vomiting, at most a slight sensation of momentary giddiness being complained of Also in the early cases in which hearing of the affected side is still present, while syringing of cold water in either ear induces a slight nystagmus, this nystagmus is not associated with vomiting or vertigo, but generally with a "floating" or swimming sensation of very transient duration

The value of the diminution of the vestibular reactability of the unaffected side, as a sign of increased intracranial pressure, was originally stated[9] in a communication to the American Otological Society in June, 1912 Confirmation of this observation has frequently occurred since that date

Examination with regard to the reactability of the vestibular apparatus in patients suffering from marked internal hydrocephalus, the result of intracerebellar mors, may give very conflicting findings at different xaminations

[9] Eagleton W P Decompression for the Relief of Disturbances of the Auditory Apparatus of Intracranial Origin Report of Three Cases with a Previously Undescribed Aural Condition Laryngoscope 1912

Figure 2 shows a large intracerebellar glial cyst, ith marked secondary hydrocephalus The child as repeatedly examined during a year and a half rior to death Spontaneous nystagmus was never resent, and the spontaneous pointing deviations observed were too slight and transient to be definite e was repeatedly subjected to the cold caloric During a violent headache, doubtless due to a disturbance the constantly present internal hydrocephalus, it s impossible to induce nystagmus or pointing deviations, a day later, however, cold water in either ear ily induced nystagmus, associated with normal inting deviations and falling tendencies, but the nysgmus was never associated with a subjective sense of rtigo, or with vomiting

It would seem, then, that alterations in increased intracranial pressure influences the possibility of the production of an induced nystagmus and of associated pointing deviations, abolishes the vomiting so often associated with the cold caloric, and lessens to a marked degree the subjective discomfort of dizziness

The absence, following cold caloric of vertigo (the only complaint frequently being a transient giddiness) and vomiting, with a reduction of the vestibular reactability of the unaffected side, may probably be regarded as symptoms of an increased intracranial pressure

It would appear, therefore, that the aural manifestations of cerebellopontile angle tumor are (1) progressive deafness, beginning with a disturbance of the proper relationship between the degree of hearing and the tuning fork reaction, especially the duration of the bone conduction to the degree of deafness, and ending in (2) total deafness, associated with (3) loss of vestibular reactability of the affected side, and during the time that the vestibular apparatus is still functionating (4) a gradual readjustment of the vestibular apparatus of the contralateral as well as the homolateral side is going on, which is manifested by (*a*) a reduction or even a temporary abolition of its reactability to the cold caloric (at least when applied in the upright position), (*b*) an absence of the vertigo and vomiting which normally accompany the induced nystagmus from the cold caloric, and (*c*) absence of spontaneous pointing deviations As the cerebellar cortex becomes affected, however, may be added (5) spontaneous nystagmus, (6) spontaneous pointing deviations, and (7) absence during an induced nystagmus of the normal pointing deviations of the homolateral side

15 Lombardy Street

Women in Industry—In December, the Committee on Labor of the House of Representatives favorably reported a bill creating a woman's division in the Department of Labor to investigate and report on all matters pertaining to the welfare of wage-earning women, and especially to investigate the competitive influence of women in the several industries, the adjustment of modern industrial mechanism and management to the nervous organization of women, and the influence of industrial employments on the subsequent home life of wage-earning women The chief of this division is to be a woman appointed by the secretary of labor The division will cooperate with the Bureau of Labor Statistics and with the Children's Bureau, in the same department The bill has the approval of the secretary of labor

CLINICAL TYPES OF LABYRINTHITIS

WITH COMMENTS ON TREATMENT *

WENDELL C PHILLIPS, MD
Fellow of the American College of Surgeons
NEW YORK

Preliminary to a discussion of the clinical types of labyrinthine disease, may I remind you that the hardness of the labyrinthine capsule and its anatomic structure seem to be so arranged by nature that they form an unusually strong barrier against invasion by a purulent process?

It is estimated by Bezold that the labyrinth becomes involved only once in 500 cases of purulent otitis media Friedich and Hinsberg, on the other hand, estimate its occurrence once in 100 cases The latter seems to me more nearly correct The most vulnerable points in the labyrinthine wall are the horizontal semicircular canal, the fenestra ovalis, the fenestra rotunda, the promontory and, from the cranial side, the internal auditory meatus The labyrinth may be invaded by a purulent process from three sources (*a*) from the middle ear, (*b*) from the blood currents, (*c*) from the meninges Our cases come chiefly from the first-mentioned type, wherein the middle ear spaces become the seat of a purulent lesion, which in turn advances into the bony structure, and during its progress attacks the labyrinthine wall and finally invades the delicate structures within the labyrinthine capsule This gives rise to our so-called purulent labyrinthitis

The following description of the various types of labyrinthine inflammation is based largely on clinical data Thus, we broadly divide internal ear inflammation into circumscribed labyrinthitis and diffuse labyrinthitis Before entering into a discussion of the subdivisions it may be well to eliminate those cases of *chronic suppurative otitis media* which have vertiginous attacks, but without disturbance in the functions of the labyrinth These patients complain of attacks of vertigo, but they have hearing, a normal rotation test, a normal caloric test and no evidence of fistula As a basis of these attacks of vertigo it is believed that middle ear disease has attacked the bony labyrinthine capsule without eroding the same This type of labyrinthine disturbance is known as paralabyrinthitis Probably there should be added to this type of paralabyrinthitis those cases in which the patient suffers for a few days from labyrinthine irritability as a result of irritation caused by injury to the stapes in performing a paracentesis Such a case was recently reported by Guntzer The family physician did a paracentesis on a patient who evidently had no infective process but was suffering from an attack of acute catarrhal otitis media

There was history of pain in the right ear for two days, no discharge, since the previous evening has been unable to walk, was dizzy and vomited Examination of the right ear showed the membrana tympani slightly reddened no bulging and a pinhead perforation about the center of the superior posterior quadrant, with a droplet of serous red discharge exuding The patient had a spontaneous horizontal nystagmus to the left and rotary on looking up, on attempting to rise fell toward the right Hearing was not impaired, no mastoid tenderness, no fever pulse 88 Diagnosis of labyrinthine irritation was made, but no assignable cause could be elicited This condition lasted ten days before the patient was able to leave the bed At a subsequent office visit the patient confided that his family physician was called the evening before Dr Guntzer's visit to the patient The patient was told he had an abscess in his ear and the doctor used an instrument to open it, when the patient at once became dizzy, nauseated, vomited and was unable to walk The labyrinthine irritation was most likely due to disturbance of the foot plate of the stapes Fortunately the middle ear and labyrinth were not infected, there was no discharge and the patient escaped the dire consequences that may have followed such an infection

---

* Read before the Section on Laryngology Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association, Detroit June, 1916

The writer has had similar experiences in patients whose ear drums have been opened by inexperienced operators, but more often these accidents result in at least an attack of serous labyrinthitis with partial or total loss of hearing, and occasionally the traumatisms are followed by acute purulent labyrinthitis with fatal results The attacks of vertigo, in such cases, are probably due to circulatory changes within the labyrinth or to transient labyrinthine irritation Their cause, however, is not definitely known

In a certain proportion of cases of paralabyrinthitis, as the disease progresses, one of two things occur either there is a sudden rupture of the infective material into the labyrinth, causing diffuse labyrinthitis, or gradual erosion of the labyrinthine capsule occurs at some place, with the walling off of the infective process, resulting in a circumscribed labyrinthitis When the latter occurs there are attacks of vertigo with nausea or vomiting, which become more severe until the patient finally seeks relief Several of these patients have come to my clinics having practically made their own diagnosis Thus they have stated that having had chronic discharging ears they recently found, on introducing the index finger into the external auditory canal, that they were seized with vertigo, nausea and vomiting In some instances we have been able to repeat this experiment and by firm pressure on the tragus, closing the external auditory canal, we have been able to elicit a positive fistula test This circumscribed labyrinthitis occurs almost invariably with chronic suppuration of the ear, either tuberculous or cholesteatomatous In such cases the disease has not invaded the endolabyrinthine spaces Thus, in such instances, although the bony capsule of the labyrinth has been eroded, the disease has not really entered the membranous labyrinth and the end-organs within the labyrinth still perform their functions or at least are capable of irritation

Such patients may have a fairly acute hearing, the rotation test and the caloric test are normal and the fistula test is positive There may or may not be spontaneous nystagmus to both sides The writer has records of five (formerly published) cases of this type and has seen many others These cases of circumscribed labyrinthitis should be differentiated from the larger class of cases of necrosis of a part or the whole of the bony capsule, with destruction of the end-organs, many of which are discovered only at the time of performing the radical mastoid operation The latter class will be referred to later in this paper

Diffuse labyrinthitis may be secondary to either an acute or chronic suppuration of the middle ear It may be metastatic or may result from an extension of meningitis through the pathways that connect the labyrinth with the subdural lymph spaces The metastatic cases usually complicate mumps Such a case was reported by the writer in the *New York Medical Journal* of Aug 2, 1913, in a boy of 18 who was suffering from mumps of great severity, during which time he had extreme vertigo and tinnitus in the right ear followed in three days by total deafness He was unconscious for four days The vertigo continued for over two weeks, when it gradually subsided After three months there was a partial return of the function of the static labyrinth, but he is still totally deaf Endocranial complications, with the exception rarely of serous meningitis, never occur in these cases

Diffuse labyrinthitis must be considered under two heads first, those cases that present symptoms, so-called manifest or acute, and second, cases without symptoms, so-called latent or chronic cases Cases of diffuse manifest labyrinthitis may occur with either acute or chronic middle ear suppuration The onset is sudden, there is rapidly developing deafness, nausea, vomiting, vertigo and nystagmus The vomiting differs from that of intracranial disease in that it is invariably associated with nausea There is no projectile vomiting The nausea bears no relationship to food The nausea and the vomiting follow movements of the head The nystagmus is of a mixed, horizontal and rotary type and is directed to the sound side With the nystagmus there are also the subjective sense of being turned and the apparent turning or spinning of objects in the environment The objective vertigo consists of reaction movements of the trunk and extremities in the direction of the slow component of the nystagmus, that is, toward the diseased ear Such patients, in attempting to walk, fall toward the diseased side or stagger toward the diseased side and must be supported There are no general symptoms, that is, there is neither rise of temperature nor acceleration of the pulse rate unless intracranial symptoms intervene We have seen all types of labyrinthitis and are convinced that even grave intralabyrinthine suppuration may occur without fever This history will illustrate

The patient had had suppuration in the right ear for five months, with no complicating symptoms up to three days before coming under observation Two days previously he had been seized with an attack of vomiting and dizziness, the latter of which had remained continuously He had no rise of temperature and did not complain of pain in the mastoid, nor was there any tenderness on pressure He was totally deaf in the right ear He had spontaneous rotary nystagmus to the left When walking he was inclined to fall toward the right He was immediately admitted to the hospital, and the radical mastoid operation was performed The mastoid antrum and cells contained a small amount of pus, and there was much granulation tissue in the tympanic cavity There was no fistula of the labyrinthine capsule, but the region of the round and oval windows was granular and soft to the probe The patient made a good recovery from the ether and passed a good night, was rational and answered questions early the following morning Later in the morning he began to show signs of meningeal irritation, with a moderate rise of temperature At noon of the same day there was a sudden rise of temperature to 105 F, he became unconscious, and died at 2 30 p m, apparently of respiratory failure

It must not be forgotten, in this connection, that diffuse labyrinthitis is a complication which often occurs during an acute exacerbation of chronic suppuration of the middle ear and mastoid, and fever, when it accompanies such a labyrinthitis, is, in all probability, due to the recrudescence of the mastoid disease

The attempt by the Vienna school to differentiate between serous labyrinthitis, so called, and suppurative labyrinthitis, so called, leaves much to be desired This differentiation rests on the retention or destruction of the labyrinthine functions However, several cases which were clearly serous, in that they occurred during the first twenty-four or forty-eight hours following the beginning of the acute middle ear abscess, have had total destruction of functions during the height of the symptoms A recent case occurring on my service at the Manhattan Eye, Ear and Throat Hospital, treated by Dr Friesner, is of this type

L H, a man, aged 42 years, was admitted Feb 25, 1916, complaining of acute suppurative otitis media on the right side He refused myringotomy Forty-eight hours after the spontaneous rupture of the drum he had an acute diffuse labyrinthitis with vertigo, nausea, vomiting, etc Twelve hours after the beginning of the labyrinthitis he was totally deaf, had a spontaneous nystagmus to both sides, more marked to the diseased side, with no falling nor vomiting Eleven days after the beginning of the acute otitis a simple mastoid operation was done The mastoid healed and the middle ear became dry He complains of tinnitus in the affected ear and is totally deaf The caloric reaction is negative Rotation to right, nystagmus 18 degrees, rotation to left, 20 degrees A diagnosis of serous labyrinthitis was made, based on the fact that the labyrinthine invasion occurred during the first few days of an acute otitis media and the symptoms were not severe Hence, despite the necessity to operate on the mastoid the labyrinth was untouched

While this differentiation is unfortunate in the selection of the terms "serous" and "suppurative," it contains this truth, namely, so long as any irritability remains in the labyrinth, extension from the labyrinth to the intracranial structures does not occur It would perhaps have been better, then, to call those cases in which the function of the labyrinth is destroyed "grave labyrinthitis," and those in which, despite the presence of labyrinthine symptoms, the function, or rather irritability, of the labyrinth was retained "mild labyrinthitis"

The diffuse manifest labyrinthitis which complicates acute middle ear suppuration may be divided into two classes, first, those which occur within the first three or four days of the disease, and second, those which occur six, eight or ten weeks after the beginning of the middle ear suppuration, in the presence of an acute mastoiditis In the first class the labyrinthitis is almost invariably mild or so-called serous It rarely leads to any intracranial complication and frequently, after the middle ear suppuration has run its course, the function of the labyrinth, at least of the static labyrinth, is restored On the contrary, the cases of labyrinthitis which complicate latent mastoiditis, and occur eight or ten weeks after the beginning of the acute suppurative otitis media, are almost invariably grave, or so-called suppurative, and frequently lead to intracranial complications, that is, meningitis As a rule, the latter cases are due to infection by one or other forms of capsulated coccus

As has been stated above, the labyrinthine inflammations which complicate the chronic suppurating middle ear may be either manifest or latent As in the cases which occur with the acute otitides, the manifest labyrinthitis may be either grave, that is, suppurative, or mild, that is, serous The suppurative labyrinthitis which is progressing to the endocranial structures, that is, arousing a meningitis, is usually accompanied by fever and headache The writer has several records of cases of this type The so-called labyrinthine symptoms are very violent and do not become progressively less severe On the contrary, those labyrinthine inflammations which are mild and have no tendency to involve the meninges have associated with them, as a rule, neither headache nor rise in temperature Furthermore, in the uncomplicated cases the labyrinthine symptoms become day by day appreciably less severe The most important signs of an extension of the labyrinthine suppuration to the meninges are headache and fever In these cases, of course, there will be total destruction of labyrinthine irritability The cerebrospinal fluid may also give us information regarding the extension of the disease to the meninges, even in the early stages

There are cases of diffuse manifest labyrinthitis of the mild type which occur after the radical mastoid operation This condition may come on any time during the healing of the radical mastoid cavity It differs from the diffuse labyrinthitis which results from the disturbance of the stapes during the radical operation, in that in the former the symptoms do not occur for the first twelve hours after the operation, whereas, in the latter the symptoms supervene at once on the patients coming out of the anesthesia By far the largest class of cases that we have met are those in which the labyrinth has been totally destroyed and in which there is no history of recent attacks of vertigo, vomiting, etc These cases are discovered solely by making the functional test of the labyrinth, a test which we invariably make before performing a radical mastoid operation Occasionally, no history of previous attacks of vertigo can be elicited In others there is an indefinite history of vertigo and vomiting which has been referred to other organs, bilious attacks, for instance The relationship between the vomiting and vertigo and the ear is not understood by them There may be a spontaneous nystagmus directed to both sides which can be observed only when the eyes are turned to the extreme angle

If the labyrinth destruction has existed for six months or more, it has been common in our experience to find a compensation test of rotation described by Ruttin The caloric test is negative, as is the fistula test, and there is total deafness When the labyrinth becomes filled with pus and granulations, there is an extension of the granulation tissue into the internal auditory canal and an occlusion of the labyrinthine artery occurs This artery is a terminal artery and its destruction entails an extensive death of the bony labyrinthine capsule, with the formation of a sequestrum In this type of cases we have frequently found a facial paralysis associated with the dead labyrinth The facial paralysis is not invariably due to neuritis We have seen cases in which a paralysis cleared up rapidly following the operation Here, in all probability, the paralysis was due to pressure either of the granulation tissue or of a sequestrum on the nerve This type of labyrinthitis is as dangerous as it is insidious, and often leads not only to meningitis, but also to cerebellar abscess and sinus thrombosis Dr John B Rae in a paper read before the Medical Society of the State of New York, May, 1916, suggested the following classification of purulent labyrinthitis acute diffuse labyrinthitis, chronic diffuse labyrinthitis, paralabyrinthitis with fistula, and paralabyrinthitis without demonstrative fistula

The treatment of labyrinthitis varies considerably and the indications for operative interference are by no means uniformly recognized There exists, furthermore, great difference of opinion as to when one should interfere in labyrinthine disease and as to the extent of that interference The indications for operation depend on the type of labyrinthine involvement In patients, for instance, with chronic suppurative otitis media, who have vertigo, but in whom there are no other signs of labyrinthine involvement, either of the auditory labyrinth or static labyrinth, the radical mastoid operation should be done, without disturbing the labyrinth This is followed, as a rule, by a cessation of the vertiginous attacks In the type known as circumscribed labyrinthitis, where there are labyrinthine symptoms with a normal rotation test, a positive caloric test and a positive fistula test, the radical mastoid operation, only, should be done Relief of the symptoms, as a rule, follows this procedure

The indication for operation in cases of diffuse labyrinthitis may be considered under two heads first, those cases of acute diffuse labyrinthitis which complicate the acute otitides, and second, those cases of diffuse labyrinthitis which occur with the chronic middle ear suppuration There are cases of labyrinthine invasion which supervene within a day or two after the beginning of an acute otitis media In such instances it is rarely necessary to do more than a free myringotomy These cases are, as a rule, mild and not prone to cause intracranial complications Even where the middle ear infection is complicated by an acute mastoiditis which requires interference, the labyrinth should not be touched And this is true even though the hearing be lost and the caloric test be negative In many of these cases the function of the labyrinth, at least of the static labyrinth, is restored There is but one exception to this rule, and that is cases in which the labyrinth has been injured by the myringotomy knife

With regard to those cases, however, in which a diffuse labyrinthitis supervenes on an acute middle ear suppuration, and latent mastoiditis of six, eight or ten weeks' duration, the story is a different one Here, the labyrinth operation is fully justifiable in connection with the mastoid operation Failure to open and drain the labyrinth may result in a meningitis, which otherwise might be avoided In the event of a diffuse labyrinthitis complicating either an acute or chronic suppurating ear, in which there is headache, fever, or any symptoms from which one might suspect an intracranial extension of the labyrinthine suppuration, the labyrinth, of course, should be opened and drained It is not to be expected that recovery will take place in the large proportion of cases, but the fact that the meningeal infection may occasionally be localized offers sufficient encouragement to warrant this attempt to save life In these desperate cases no half-way measures are permissible and the Neumann operation, in which the bone is entirely removed, including the border of the internal auditory canal, together with drainage of the cerebellar spaces, is the ideal procedure

Perhaps the greatest difference of opinion exists regarding those cases of diffuse labyrinthitis which complicate chronic suppurating middle ears This is particularly true of the manifest variety, that is, cases in which there are labyrinthine symptoms and in which the functional test shows complete deafness and loss of irritability of the static labyrinth According to the Vienna school here are the indications for labyrinthectomy If the labyrinth has been invaded by the suppurative process and has been destroyed, the functional tests will, of course, show total absence of hearing and total loss of static irritability Many of these cases are discovered accidentally in making the functional test before doing the radical mastoid operation It is this class of cases which undoubtedly, in time gone by, led to a meningitis of unknown origin after the radical mastoid operation A trauma, incident to the radical mastoid operation, frequently causes the lighting up of the labyrinthine suppuration which has previously been walled off from the meninges Therefore, in these cases it is wiser, in addition to the radical mastoid operation, to open and drain the labyrinth In many instances this type of case is associated with facial paralysis and part of the labyrinthine wall has been sequestered Wherever there are signs of an intracranial complication, combined with a destroyed labyrinth, the posterior fossa should be uncovered, irrespective of the type of labyrinth operation performed

DIFFERENTIAL DIAGNOSIS BETWEEN PURULENT LABYRINTHITIS AND CEREBELLAR LESIONS *

ISIDORE FRIESNER, M D
NEW YORK

I should like to state at the outset that I have not attempted a complete resume of the differential diagnosis between labyrinthine and cerebellar lesions That has been done very often and very well I have rather sketched the differentiation from the point of view of cerebellar symptomatology, paying particular attention to one or two phases of the question

Even though the occurrence of disturbance of balance, vomiting and nystagmus are strongly suggestive of the most common cause of such symptoms, namely, labyrinthitis, it must not be forgotten that other conditions, too, may arouse almost identical phenomena Among the conditions which may cause symptoms similar to those of labyrinthine disease the most important are lesions in the cerebellum and it is necessary, therefore, that the latter be differentiated from labyrinthine disturbances

It is, perhaps, best to discuss this differentiation from the point of view of cerebellar symptomatology under several heads first, general symptoms of cerebellar lesions, which may be due either to increased intracranial pressure or, in the case of abscess, to the inflammatory process in the cerebellum and, second, focal symptoms of cerebellar lesions, which may be either symptoms of disturbance in movement or symptoms of disturbance in the vestibular apparatus

In uncomplicated labyrinthitis there is very rarely headache In cerebellar lesions there is almost invariably headache With abscess of the cerebellum the headache may not be constant or it may be dull and boring, with unbearably severe exacerbations, but it is present in at least 90 per cent of cases With cerebellar lesions there may be disturbance of the sensorium, disturbance of respiration, bradycardia, optic nerve changes, paralysis of the cranial nerves, none of which, with the exception of disturbances in the eighth nerve, and occasionally the seventh, ever occur with labyrinthitis There is vomiting with cerebellar lesions, as well as with labyrinthine, but in the latter the vomiting is never of the projectile type, that is, it is always associated with nausea Furthermore, the vomiting with labyrinthitis becomes daily less, so that after a few days it ceases On the other hand, the vomiting with cerebellar abscess is frequently projectile in type and is particularly persistent, much more so, as a rule, than with abscess in the temporosphenoidal lobe

With cerebellar abscess and with labyrinthitis the temperature may be normal, with abscess it may be subnormal or there may be fever, but uncomplicated

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association Detroit, June, 1916

purulent labyrinthitis of itself never causes a considerable rise in temperature With abscess there is frequently marked emaciation and there may be pathologic changes in the cerebrospinal fluid In uncomplicated labyrinthitis these, of course, do not occur

The focal symptoms of cerebellar lesions which help to differentiate them from labyrinthitis may be divided into symptoms of disturbances of movement, and symptoms of disturbances of the vestibular apparatus With cerebellar lesions there may be *hypermetria,* asynergy, adiadokokinesis, tremor, disturbances in speech, atony or hypotony, catalepsy, hemiparesis and fixed attitude of the head None of these occur with labyrinthitis

Cerebellar lesions, however, may have in common with disturbances in the vestibular apparatus abnormalities in the voluntary movements of the trunk and of the extremities When these disturbances in movements result from disease in the labyrinth or in the vestibular nerve, they are dependent for their direction on two elements, first, impulses from the static labyrinth, and secondly, impulses from the muscles and joints of the neck Changes in these peripheral impulses cause alterations in the direction of the deviating movements Thus, if, as a result of labyrinthine disturbance, a person has a spontaneous nystagmus directed to the right, when he attempts to stand erect he will fall to his left, if he faces forward The tendency to fall, then, will be in the direction of the slow component of his spontaneous nystagmus If, however, the afferent impulses to the cerebellum from the muscles and joints of his neck are changed by turning his face to one or the other shoulder, there will occur a change in the direction toward which he tends to fall If this objective imbalance is due solely to a pathologic disturbance of the vestibular impulses, the tendency to fall will always be in the direction, in space, of the slow component of the resulting nystagmus This relationship between the spontaneous nystagmus and the deviations is constant and characteristic of labyrinthine lesions and applies to the extremities as well as to the trunk In the presence of a nystagmus of vestibular origin to the right, the arms held stretched out in front of the body will deviate to the left and the direction of this deviation will change with alterations in the position of the head

On the contrary, the objective disturbances of balance due to cerebellar lesions, that is, the falling and the deviations of the extremities, bear no definite relationship to the spontaneous nystagmus if this be present It is believed, although by no means proved, that the vermis of the cerebellum has to do with what Edinger called the statotonus, that is, the development of such tonic influences to the voluntary muscles as cause the body to be held erect in space In disease of the vermis there is a disturbance of body balance and a tendency to fall, usually toward the side of the lesion The direction of this tendency to fall is central in its origin and is not influenced by changes in the peripheral impulses Thus a person who has a positive Romberg, falling to the right, as the result of a cerebellar tumor, will fall to the right irrespective of any changes in the position of his head Furthermore, a spontaneous nystagmus often accompanies cerebellar lesions, and if this is present, the direction of the falling will not of necessity be to the side of the slow component What has been said regarding the tendency to fall applies equally to the deviations of the extremities

So that, with regard to their influence on voluntary movements, the chief differential point between cerebellar lesions and vestibular lesions lies in the fact that in the former the falling and the deviations of the extremities are central in origin and their direction is not influenced by changes in the peripheral or afferent cerebellar impulses, whereas in the latter, changes in these peripheral impulses, aroused by changes in the position of the head, cause alterations in the direction of both the falling and the deviations

With cerebellar lesions, in addition to spontaneous falling and deviations of the extremities, there may be a loss of the reaction movements which occur normally in response to artificially aroused vestibular impulses

The response to functional tests in the presence of labyrinthine suppuration, that is, the loss of hearing, the loss of reaction to the caloric, rotation and fistula tests with the spontaneous nystagmus, etc, are so familiar that they require merely mention here I dare say that all those who have performed the functional tests of the static labyrinth in the presence of cerebellar tumors or abscesses have seen the so-called enduring nystagmus With cerebellar lesions a caloric nystagmus directed to the side of the lesion frequently lasts much longer than the normal two and one half or three minutes This phenomenon is believed to be due to the loss of the inhibitory influence of the cerebellum on the vestibular centers In two cases in which large hernias of the cerebellum occurred after decompression operations in the posterior fossa I attempted by firm pressure on the hernia, after the manner described by Barany, to influence the duration of the caloric nystagmus directed to the affected side In one of these I was successful, but in the other I failed, the nystagmus lasting the normal two or two and one half minutes

I have purposely left for the end of this paper the consideration of the spontaneous nystagmus which sometimes accompanies cerebellar disease As the result of our experience in the intervening time Dr Braun and I, in our book on cerebellar abscess recently published, have reiterated a statement made about two years ago in a paper read before the neurologic section of the New York Academy of Medicine, namely, that the nystagmus of central origin often cannot be differentiated clinically from that due to labyrinthine disease We have been unable to recognize any essential difference between the nystagmus of central origin and that due to disease of the labyrinth or vestibular nerve That there are minor differences is evident Grey, in his report of cerebellar cases from the Peter Bent Brigham Hospital, although agreeing in the main with the statement above, calls attention to the fact that in their experience the nystagmic movements are coarser with subtentorial lesions It is true they are often more like the caloric nystagmus which one sees in the blind With acute diffuse labyrinthitis the nystagmus is almost invariably directed to the opposite side With cerebellar lesions the direction of the nystagmus may vary at different times Neumann has shown that this occurs with cerebellar abscess With tumors the direction of the nystagmus may vary sometimes with changes in the position of the head Furthermore, with tumors it is more common to observe a nystagmus in the anteroposterior vertical plane I have never seen this with vestibular lesions But in the fact that it is a rhythmic movement of both eyes and in the planes in which these movements occur with the exception cited above, the nystagmus of central origin is essentially identical with that of peripheral origin.

There is, however, a considerable difference in the behavior of the two. The nystagmus with diffuse labyrinthine disease grows appreciably less in intensity from day to day, while that of central origin remains the same or may even increase in intensity.

Finally the attempt to consider the nystagmus of central origin as an oscillation, an asynergia to be differentiated from that of peripheral origin by the fact that in the latter the eye movements decrease on fixation of the vision, is not borne out by our experience. We have but recently seen a circumscribed labyrinthitis, a diffuse labyrinthitis and a fracture through the labyrinth, in all of which the spontaneous nystagmus was definitely increased on fixing the vision on the index finger held close to the patient's nose, and while this is, in all probability, not the rule, it is, at all events, too frequent an occurrence to be useful as a means of differentiation.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. EAGLETON, PHILLIPS AND FRIESNER

Dr. Horace Newhart, Minneapolis: I wish to emphasize the importance in all suppurative cases of making regular systematic examinations of the labyrinthine and cerebellar functions. By doing so we could undoubtedly reduce materially the mortality which exists with all endocranial complications of otitic origin. Take the statistics for cerebellar abscess. Unoperated, the mortality is practically 100 per cent., while the records of those best fitted to operate in such cases show a mortality of 40 per cent. Patients with cerebellar abscess too often come under observation in the latter stage of the manifest period, when interference cannot be expected to yield better results than those stated. But there is another group of cases, including the many chronic cases of temporal bone involvement, and the acute suppurative cases, if we were to apply to these our regular routine tests of the labyrinthine and cerebellar functions, we should gain some light as to what is going on within the cranial cavity, and by early operation might safely intervene before the appearance of a diffuse meningitis, with very appreciable reduction in mortality. Of great assistance in making a diagnosis of endocranial complications are the results of ophthalmoscopic and ocular examinations. Alexander, Neumann and O. Ruttin stated that in at least 50 per cent. of cases of cerebellar involvement originating in the labyrinth there are changes in the fundus. These changes are not always marked; only in the later stages, with decided increased endocranial pressure, is there a true choked disk. But the distinct alteration of the retinal vessels, usually unilateral and corresponding to the side involved, are sufficiently constant to be of diagnostic value. Disturbances arising from increased pressure affecting the cranial nerves come relatively late, but it is not unusual to find a diplopia with cerebellar abscess. In three cases coming under observation during the past six months, all terminating fatally, from several days to two weeks before a diagnosis of a terminal meningitis was made, the patient had complained of distinct throat symptoms with painful deglutition, and this without any discoverable lesion of the throat. This suggests somewhat the possibility of very early bulbar irritation associated with these cases of endocranial complication in the posterior fossa.

Dr. Isaac H. Jones, Philadelphia: A woman was referred to me with a diagnosis of tumor of the right cerebellar hemisphere. It was evident that either the ear tests were incorrect or there was nothing the matter intracranially. The right ear responded poorly; douching the left with both hot and cold water showed normal nystagmus and normal past-pointing in both directions, suggesting normal brain stem and cerebellum. Operation was postponed; she became perfectly well, has had a baby and has remained in perfect health ever since. Unquestionably it was a labyrinthitis and not brain tumor. A man getting off a train has a sudden explosive sound in his ear, falls to the platform, is dizzy and sick in bed for a week. Right ear is stone deaf, static and cochlear; Wassermann markedly positive. Could anything be simpler to diagnose—destruction of the labyrinth? But it was nothing of the sort; it was a beginning acoustic tumor. Later he showed spontaneous vertical nystagmus upward, which together with absence of responses from one ear make the diagnosis of cerebellopontile angle tumor with pressure on the brain stem. Necropsy showed cerebellopontile angle cyst. Man, neurologic diagnosis, right frontal tumor; ear tests suggested left cerebellopontile angle tumor. However, they operated in the right frontal region. Necropsy showed left cerebellopontile angle tumor. An apparently healthy man with headache showed normal labyrinths and eighth nerves and yet the vertical canals failed to produce any responses; horizontal canals produced normal nystagmus but no vertigo. This phenomenon-complex indicated pressure within the fourth ventricle; this diagnosis appeared ridiculous because the man seemed in such perfect health. That night he was rushed to the hospital unconscious; next day he regained consciousness but complained of agonizing headache. Many physicians and neurologists pronounced it hysteria. We stuck to our conviction of an organic lesion in the fourth ventricle. Necropsy three days later showed abscess in the fourth ventricle. Internal hydrocephalus shows absence of reaction from vertical canals and impaired vertigo from horizontal canals. Our operative and postmortem findings suggest that the horizontal canal fibers are confined to the medulla and inferior cerebellar peduncle, whereas vertical canal fibers traverse the pons and middle cerebellar peduncle. Cerebellopontile angle tumor shows (1) "Crossed" past-pointing; both arms point inward or both arms point outward regardless of type of stimulation. (2) Not only is there total absence of reaction from ear on the side of tumor but vertical canals of opposite ear fail to produce responses, whereas horizontal canal of opposite ear gives normal reactions. This is due to pressure on the pons involving vertical canal fibers from opposite ear. In one case a decompression was done and then stimulation of the opposite side gave normal responses, showing clearly that pressure had been removed from the vertical canal fibers.

Dr. J. Holinger, Chicago: It seems to me that we have become too sanguine by the results of the examination of the static labyrinth, and are prone to forget the examination of the ear by means of the speculum and tuning forks. The statistics of brain tumors show that tumors of the acoustic nerve are not very rare, yet they are rarely diagnosed. Tumors of the acoustic nerve are only discovered at the necropsy. As to a division of the nerve supplies of the horizontal and the vertical semicircular canals, the same is true of the vestibular and cochlear nerves. This division may also give us pointers in trying to locate a tumor, as well as the division of the nerve supply of the horizontal from vertical canals. All of these points are equally important in fractures of the base of the skull, and in locating a blood-clot. The following incident may be of interest. Last December I saw a patient who had had a fall on a slippery sidewalk, after which he got up and walked home. A few days later he became drowsy. When I examined him his mind was not clear, but he still reacted to some questions, slowly and loudly put, and several times repeated. The examination by means of speculum and tuning fork allowed me to make a diagnosis of fracture of the base, running from the external canal of the right ear crossing the pyramid of the temporal bone and following the course of the eustachian tube. Meningitis; caloric test was contraindicated; the fluid might have gone into the skull cavity. Three days later the patient died, and I was requested by the coroner's jury to hand in a report independent of the coroner's postmortem report. A colleague who followed the whole proceedings told me afterward that my description of the fracture was more accurate than the coroner's.

Dr. George W. MacKenzie, Philadelphia: I wish to endorse practically everything Dr. Eagleton said, particularly with reference to the early symptoms that are possible of solution by careful otologic examination in cases of brain tumor long before there are symptoms of marked intracranial pressure, and, too, in reference to basal fractures In cases of basal fracture, Bezoldt found that one fourth of the fractures involve the temporal bone A basal fracture may involve the middle ear alone, the internal ear alone, or both combined In a case of basal fracture involving the middle ear alone, functional tests disclose the typical findings of involvement of the conducting apparatus When the inner ear is involved, there are the typical findings of a disease of the perceiving apparatus, furthermore, when the inner ear is involved, the facial nerve is usually involved with it It is important in all cases of basal fracture, therefore, to make a careful examination of the hearing function as well as the static function, since it gives us an important guide as to the prognosis and method of operation to be followed I recall one instance in which a general surgeon removed the stirrup in a case of fracture of the tegmen tympani, causing a pronounced deafness that would not have followed had the stirrup been left alone On the other hand, there are many cases of fracture through the labyrinth in which operation could be done successfully which are allowed to go on to meningitis and death simply through neglect to operate I believe all fractures involving the base should be examined carefully by the otologist and in case the temporal bone is involved, I would urge that the otologist perform the operation rather than leave it to the general surgeon I also want to mention a case in which I had diagnosed a tumor of the internal auditory canal, involving the seventh and eighth nerves I suggested the diagnosis of cysticercus, because the man had lived among dogs all his life In the decompression operation done later by a general surgeon, a great portion of the occipital bone was removed and the tumor not reached The patient died a short time after from shock The postmortem examination proved the correctness of my diagnosis Had this patient been operated on by an otologist following the method of removal of the labyrinth, slightly modified, the results would have been more favorable My plea is for accuracy in methods of examination, using what knowledge we have concerning the functions of the inner ear and their deviations from the normal when they are involved One of the gentlemen mentioned that a patient had a nystagmus to both sides There is no lesion of the vestibular apparatus or cerebellum that can produce a nystagmus to both sides When such findings are recorded, it is because of a mistaken observation Nystagmus of reflex origin is always in one definite plane and direction and should be observed with the patient looking straight ahead while the eyes are in a condition of rest When we record our observations in nystagmus in the side positions, we are bringing in an additional factor which has nothing whatever to do with the reflex

DR LEWIS FISHER, Philadelphia In the analysis of cases showing vestibular symptoms, in order to get as clear a conception of this subject as possible, we attempt to visualize the anatomy of the parts concerned We believe that the vestibular apparatus starts at the internal ear, and is connected with the various portions of the central nervous system by means of nerve paths The internal ear, however, is by far the most important portion of this vestibular apparatus Disturbances in equilibration cannot occur unless there is interference with this vestibular apparatus at some point The same can be said of nystagmus it can occur only when there is disease along the fibers which run to the eye muscles producing nystagmus We try to remember that in the internal ear as well as in the eighth nerve, apart from the acoustic fibers, there also run two other sets of fibers, one set to the eye muscles producing nystagmus, and another to the cerebral cortex, producing dizziness But these paths do not run together all the way, in the brain stem they part company The nystagmus fibers run to the eye muscles, while the fibers carrying the vertigo stimuli have the cere*bellum as their first objective point* These paths are different for the two sets of canals The horizontal canal fibers enter the cerebellar nuclei by way of the restiform body, and from there, leaving by way of the superior cerebellar peduncles, go to the temporal lobes of the cerebrum The vertical canal fibers continue higher up in the brain stem and enter the cerebellum by way of the middle cerebellar peduncle There is always an inseparable association in the minds of authors between nystagmus and past-pointing Bárany in his writings says that certain deviations in pointing occur in relation to either one component of the nystagmus or the other This is to be greatly regretted We have shown by experiments at the University of Pennsylvania that the slow component of the nystagmus has absolutely nothing to do with the dizziness and past-pointing that we are able to induce in patients by stimulating the labyrinth When such a relation appears it is simply a coincident Thus The rule as generally postulated, namely, that the past-pointing is in a direction opposite to that of the nystagmus, is not correct, for we have shown that if an individual is turned to the right with the head back, the resulting nystagmus is to the right, but the past-pointing is also to the right, and we believe that this subject could be greatly simplified if this differentiation between the two reactions were more generally understood In cerebral abscess, or tumor of the brain stem, or of any portion of the brain all the vestibular phenomena are produced either by irritation or by destruction of some of the vestibular fibers In patients exhibiting such vestibular disturbances only a careful examination of the ear can tell us whether the disturbance is in the labyrinth and eighth nerve or whether it is intracranial If in the latter, we are able to tell just where within the cranium these pathways have been interfered with For example, if in a case presenting vestibular symptoms we are able to produce nystagmus but no vertigo with past-pointing, we know that the disturbance must be in the vertigo pathways between the cerebellar peduncles and temporal lobes If, on the other hand, we stimulate the labyrinth and are able to produce dizziness with past-pointing but no nystagmus, then the interruption must be either in the pons or medulla oblongata Generally speaking, a careful examination of both labyrinths, and especially of each canal separately, enables us to test the integrity of the different pathways and locate lesions with considerable accuracy

DR CHESTER C. COTT, Buffalo Tumors which press on the auditory nerve or involve this nerve in its growth often cause a sudden onset of symptoms This is due to the fact that the resistance of the nerve is suddenly overcome. Before the onset of severe symptoms an examination would reveal cochlear nerve degeneration Later there occurs a severe attack of dizziness very likely following a trauma which the patient usually ascribes as the cause

DR ISIDORE FRIESNER, New York In addition to the anatomic reasons for the priority of auditory symptoms in tumors not only of the cerebellum or pons, but also of the nerve, we must not forget that there is a very marked difference in the viability—and conversely in the destructibility—of the two branches of the eighth nerve Not only is this true as far as the nerve trunk itself is concerned when subjected to pressure or involvement by a tumor mass, but Alexander has shown, from the examination of labyrinths which were subject to suppurative process, that this difference extends completely throughout the labyrinth itself For instance, the hairs, which are biologically distinct from the hair cells, show a difference in viability when they are subjected to the presence of pus in the intralabyrinthine cavities So with the tumor which involves, as far as its gross structures are concerned, the auditory and vestibular nerves equally, the primary disturbance will be in the auditory function—tinnitus or deafness Furthermore, there have been reported numerous cases in which in addition to the eighth the facial nerve was involved, and yet there was no paresis So that in the order of their susceptibility we consider the auditory nerve, but second the vestibular, and last, the facial In regard to nystagmus to both sides, it is true that in many of these cases the nystagmus movements are more marked to one side than to the other With brain tumors however, I have seen a vertical nystagmus directed not only upward but also downward. Of course this cannot be a physiologic nystagmus. It is a rhythmic movement of both eyes, and if we do not call this nystagmus both upward and downward, I do not know what we should call it.

Dr. Wells P. Eagleton, Newark, N. J.: We have all seen cases in which the otologists should be called in. Our general hospitals are crowded with otologic cases. Every neurologic ward has its otologic problems, and we could give great assistance there, if we could see the patients in time to make an early diagnosis.

THE FATE OF PHENOLSULPHONEPHTHALEIN WHEN INJECTED INTO THE ANIMAL ORGANISM

FACTORS OTHER THAN THE KIDNEY INFLUENCING ITS "RETENTION": PRELIMINARY REPORT *

EDWARD C. KENDALL, Ph.D.
ROCHESTER, MINN.

During the past few months I have been engaged in a study of the physiologic action of the thyroid. The general scheme followed has been to treat dogs with a continuous injection[1] of amino acids, sugars and other substances in conjunction with the injection of the active constituent of the thyroid, and to study the effect of the thyroid on the metabolism of the animals. Some animals respond vigorously, the injection of the thyroid constituent producing very high pulse rate and a great increase in the respiration, accompanied by an extremely severe general tetany and terminating in a temperature which occasionally reaches as high as 112. It was soon found that all animals can be divided into two classes, those which give this reaction and those which do not.

For certain reasons it seemed probable that the condition of the animal could be foretold by the use of some substance which would be a criterion prior to the injection of the thyroid hormone. Phenolsulphonephthalein was used for such a test and a few trials demonstrated that in those animals which had a high phenolsulphonephthalein retention, little or no effect was produced by the injection of the thyroid, and in those animals having a low phenolsulphonephthalein retention a vigorous response to the thyroid might be expected. The administration of the phenolsulphonephthalein was changed somewhat from the usual procedure, and 1 c.c. per hour of the standard solution (6 mg.) was injected continuously during the entire experiment. By taking samples of the urine every fifteen or thirty minutes, the exact condition of the animal could be closely followed. At first it seemed that the type of metabolism going on had some influence on the amount of phenolsulphonephthalein excreted. With a constant injection of glucose we have recovered as high as 98 per cent. of the phenolsulphonephthalein injected. This high return was not momentary but continued for several hours. When a dog was injected with amino acids it was found that a rather low phenolsulphonephthalein output resulted, and in one instance a maximum excretion of 47 per cent. was found. In a second animal the maximum was 52 per cent. As it seemed probable that the type of metabolism going on in the animal was one factor controlling the output of phenolsulphonephthalein, we were greatly surprised to find that on the injection of amino acids in a third dog the phenolsulphonephthalein output ranged from 80 to 86 per cent. for many hours. It was necessary, therefore, to go further back for an explanation of the phenolsulphonephthalein retention.

In order to determine whether the phenolsulphonephthalein was absorbed and held in the tissues, the dogs were killed and their organs examined for phenolsulphonephthalein. In no case were we able to recover any of the dye except slight traces in the blood. Phenolsulphonephthalein retention, therefore, assumed a new aspect; that is, phenolsulphonephthalein retention really means phenolsulphonephthalein destruction. The possible mechanism of the destruction of phenolsulphonephthalein may be, first, the hydrolytic cleavage of the substance; second, the oxidation of the compound, and third, reduction.

The first is improbable because it is unlikely that there is a specific enzyme in the body which will accomplish it. When an attempt was made to oxidize phenolsulphonephthalein with hydrogen peroxid, it was found to be extremely resistant. A similar trial with nascent hydrogen showed that it is easily reduced. It thus seemed probable that phenolsulphonephthalein in the body is destroyed by reduction. In order to establish this point a dog was killed, its various organs ground to a fine mash, and 1 c.c. of phenolsulphonephthalein was mixed with the tissues. After standing some hours the amount of phenolsulphonephthalein destroyed was determined. It was found that muscle and intestine destroyed a large percentage, that the liver destroyed practically 100 per cent., and that the spleen, pancreas, lung and kidney destroyed almost none.

If the destruction of phenolsulphonephthalein in the tissues is caused by its reduction, the presence of an oxidizing atmosphere should prevent the destruction of the dye. To show this a liver mash was mixed with phenolsulphonephthalein, one portion was covered with liquid petrolatum to exclude oxygen, a second was left exposed to the air, and through a third portion air was bubbled. In the portion in which no oxygen was present, the phenolsulphonephthalein was totally destroyed; in the dish standing open, a large percentage, but not all, was destroyed; and in the portion through which air was bubbled, only a portion of the phenolsulphonephthalein was destroyed. Blood both in the oxidized and reduced form will not destroy phenolsulphonephthalein. Its destruction in the tissues is caused by a more powerful reducing action than that of completely reduced hemoglobin. Since blood is the carrier of oxygen in the body, it seemed probable that there would be a difference in the destruction of phenolsulphonephthalein by a perfused liver if the blood in the perfusing fluid was oxygenated or reduced. In the presence of oxygenated defibrinated blood, as much as 80 per cent. may be recovered after perfusion of a liver. In contrast to this, 95 per cent. of the phenolsulphonephthalein perfused through a kidney was recovered, although reduced hemoglobin was used.

These experiments have been confirmed and enlarged with the object of showing the presence of an enzyme in the tissue which is capable of exerting a very strong reducing action. It is not probable, however, that this enzyme acts on the phenolsulphonephthalein itself. Phenolsulphonephthalein is not affected by mild reducing agents such as hydrogen sulphid, sulphurous acid,

ammonium polysulphid and formaldehyd, and apparently will not react except with nascent hydrogen itself The presence of reducing enzymes in plant and animal tissues has long been known, and the fact that phenolsulphonephthalein is apparently reduced only by nascent hydrogen and is destroyed in the animal organism furnishes grounds for ready speculation concerning the possibility that hydrogen is produced by the tissues of the body If hydrogen itself is not produced, there is at any rate a most powerful reducing substance The reducing action appears to proceed according to the laws generally followed by enzymes, that is, it is destroyed by heat, and its activity is greatly influenced by minute amounts of acid and alkali and also by the presence of sugars and other materials The fact I wish to emphasize is that this enzyme continues to exert reducing action both in the presence and in the absence of oxygen Is it not probable that a primary step in metabolism is a reduction with the production of hydrogen which then reacts with hemoglobin? If the supply of oxygen from hemoglobin is adequate for the reducing action of the cells, then phenolsulphonephthalein can no longer be reduced, as it is protected by an excess of oxygen However, if the reducing action of the cells is greater than can be satisfied by the oxygen from the hemoglobin, phenolsulphonephthalein is reduced Fundamentally, therefore, what the phenolsulphonephthalein tests show is the ratio between the rate of reduction and the supply of oxygen in the body Just what the phenolsulphonephthalein shows in any particular case obviously depends on so many factors that it is impossible to localize all the effects in any one organ

RESULTS OF TESTS

Tissue	Amt Gm	Phenolsulphonephthalein Cc.	Treatment	Phenolsulphonephthalein Recovered Per cent
Sheep s liver	50	1	Undiluted + liquid petrolatum	0
Sheep s liver	50	1	Undiluted exposed to air	Trace
Sheep's liver	50	1	150 c c 0 8% NaCl + liquid petrolatum	47
Sheep's liver	50	1	150 c c 0 8% NaCl exposed to air	78
Sheep s liver	50	1	150 c c 0 8% NaCl aerated	90
Human liver	25	1	40 c c 0 8% NaCl	10
Human liver	25	1	39 5 c c 0 8% NaCl + 0 5 c c 3% H O	30
Human liver	25	1	35 c c 0 8% NaCl + 5 c c 3% H O	30

* Enzyme entirely destroyed
† Enzyme partially destroyed
‡ Blood + phenolsulphonephthalein stood 30 hours

The presence of a slight acidosis increases the capacity of the tissues for absorption so that they will retain the dye so firmly that it cannot be washed out with physiologic salt The addition of a small amount of sodium carbonate will counteract this, and physiologic salt will then remove the dye from the tissues Furthermore, in the presence of an increase in the hydrogen ion concentration, the action of the enzyme is apparently more vigorous, resulting in greater destruction of phenolsulphonephthalein Acidosis is not controlled by any one organ, but is a condition which may result from many causes That it plays its part in the destruction of phenolsulphonephthalein cannot be doubted Another great factor is the rate of the circulation of the blood If for any reason the blood passes through the tissues at a slightly diminished rate, the amount of oxygen supplied to the tissues is reduced and the excess necessary to protect phenolsulphonephthalein from destruction is no longer present, thus a greater destruction of the dye results Another factor would be a condition of anemia, in which the oxygen-carrying capacity of the blood is greatly reduced Finally also the lungs must play an important part, as improper aeration of the blood would cause inability of the hemoglobin to furnish enough oxygen to protect the phenolsulphonephthalein from destruction We have produced a drop in phenolsulphonephthalein output from 76 to 19 per cent in an animal receiving a continuous injection of phenolsulphonephthalein, by simply interfering with its respiration When the respiration was again normal, the output rose to 60 per cent If the kidney does not readily pass the dye, it is returned to the circulation and the tissues have a prolonged action on it, resulting in great destruction

There is one condition which I should like to mention in which this enzyme with its ability to produce extremely powerful reducing substances, if not nascent hydrogen itself, may play an important part It seems highly probable that in uremia, when there is a condition in which phenolsulphonephthalein is reduced, other substances must be reduced, not directly by enzyme action but by the action of hydrogen or its substitute Such reduction going on constantly within the tissues of the body is at least theoretically capable of producing compounds which normally could not be present, and to these compounds originating within the organism itself we may attribute some of the clinical symptoms

For the treatment of blood, tissues and other bodily fluids so that a phenolsulphonephthalein test may be made, a method somewhat similar to one already described has been used[2] The material to be tested is made to some definite volume and placed in a beaker From 10 to 15 c c of concentrated ammonia are added, and from 5 to 10 gm of calcium chlorid The solution is then boiled The calcium precipitates the proteins, and this precipitation, in the presence of ammonia, leaves the dye in solution If there is a slight opalescence following this treatment, it has been found that the addition of ammonium phosphate, which will precipitate calcium phosphate, will remove the last traces of turbidity and leave a solution which can be accurately matched with the standard The water is allowed to boil off until somewhat below the original volume The solution and precipitate are returned to the original measuring vessel, cooled, made up to the original volume and filtered

In the tests recorded in the accompanying table, the same procedure was followed throughout. The finely ground tissue was mixed with 1 c.c. of standard phenolsulphonephthalein solution and allowed to stand undiluted or diluted with physiologic salt and other additions, as shown. The solutions were preserved with toluene, and bacterial action can be ruled out as a possible factor of the destruction. Dilution appears to influence greatly the amount of phenolsulphonephthalein reduced, probably by simply diluting the concentration of the substance reducing the phenolsulphonephthalein. Another factor which may be of influence here is the diminished activity of the diluted solution. The partial destruction of the enzyme by simply allowing the liver mash to stand in the laboratory until in a putrid condition is of interest. Although there is no doubt about the presence of bacteria in this case, and although bubbles of gas were being given off by the solution, the destruction of phenolsulphonephthalein was much less than before the liver had become decayed. This loss of action when the tissue became decayed suggests that the reducing enzyme is more active in living functioning cells, and that the destruction of phenolsulphonephthalein in these experiments and in the body is not caused by the degenerative processes going on in dead cells. Whether or not the favoring action of glucose on the destruction of phenolsulphonephthalein is of significance is not now certain, but it is of interest to note that the solution causing the greatest destruction of phenolsulphonephthalein contained small amounts of glucose.

STERILITY STUDIES

WITH PARTICULAR REFERENCE TO WEAK SPERMATOZOA, DIAGNOSIS AND TREATMENT *

V. D. LESPINASSE, M.D.
CHICAGO

To satisfactorily diagnose and treat sterility it is essential that it be considered a dual problem, involving both the husband and wife. At the present time there is a marked lack of cooperation between gynecologists and genito-urinary surgeons in the diagnosis and treatment of this type of patients. There are types of sterility which are definitely due to the male; there are also types, fewer in number, however, and much harder to diagnose, that are definitely due to the female, and there is a large class of patients who come stating that the wife has been examined and nothing can be found and the husband has been examined with a negative result, but no children appear. This type of case has, up to the present, been attributed to the woman, but on very insufficient evidence. Evidently something is wrong somewhere; hence my plea is that these cases should be undertaken at least with very marked and close cooperation between the different men, or one man should qualify himself sufficiently to work out these cases alone. In determining the cause of sterility of a given couple it should be considered under the following heads:

1. Obstructions in the sexual tract of the male.
2. Obstructions in the sexual tract of the female.
3. Absolute failure of, or imperfect development of, the essential male elements.
4. Absolute failure of, or imperfect development of, the essential female elements.
5. Alterations in the secretions of the female sexual tract so that her secretions are destructive to the life of the spermatozoa.

Obstructions in the Male Generative Tract.—This class of cases is easily diagnosed as they discharge a semen with complete absence of spermatozoa. The only treatment for these obstruction cases is surgery, with removal or anastomosis around the obstruction. What particular operation is necessary to be performed depends on the location of the obstruction. The possible operations are vaso-epididymostomy, either with the vas and epididymis of the same side or the vas and epididymis of opposite sides; Lespinasse sac operation, resection of the vas and end to end union with the vas on the same side or with the vas on the opposite side. Urethral obstructions should receive appropriate dilatation or operation.

Obstructions in the Female Sexual Tract.—There are two places in the female tract where obstructions are likely to occur, namely, the tubes and the cervix. Tubal obstructions can be definitely diagnosed by laparotomy and catheterization of the tubes. If this is not considered feasible the diagnosis must be made by inference either by a history of some pelvic disease likely to produce adhesions or (after determining that the husband has a normal sperm) by the recovery of motile sperm from the uterine fundus several hours after coitus. To aid us in recovering sperm from the fundus it is advisable to do a direct uterine insemination and from four to twenty-four hours later examine the uterine secretions for living sperm. If the sperm are actively motile we infer that the cause of the sterility is either tubal obstruction or a defect of ovulation. Cervical obstructions can be cured by direct uterine insemination easier than by operation directly on the cervix, as these obstructions are slight and do not prevent the passage of the impregnating catheter. No doubt there are cases in which it will not pass, but they are extremely rare.

Absolute Failure of, or Imperfect Development of, the Essential Male Elements.—This is the type of case that I particularly wish to call to your attention and to study carefully. Semen is easily obtained and should be carefully studied, not only as to spermatozoa, but as to all the other elements as well. Pus is present occasionally and there are marked differences in the coagulating properties of the semen of different men, although sterile semen shows much less coagulating power than nonsterile. The spermatozoa deserve special study. The function of spermatogenesis is one of the highest and most differentiated of bodily functions. It is quite complicated and hence one would expect to find many defects and abnormalities in its product (namely, spermatozoa).

Process of Spermatogenesis.—Spermatogenesis is affected adversely by many things, particularly the Roentgen ray, also by environment and the state of health; in debilitated and weakened conditions spermatogenesis ceases or is markedly defective. Diet also has a great influence on the production of the spermatozoa and in animals the season is a very important factor. In man, however, there is no definite breeding season, as is proved by the fact that the same number of babies is born each month of the year. All these factors influence spermatogenesis in a destructive way. To influence spermatogenesis in ammonium polysulphid and formaldehyd, and apparently will not react except with nascent hydrogen itself The presence of reducing enzymes in plant and animal tissues has long been known, and the fact that phenolsulphonephthalein is apparently reduced only by nascent hydrogen and is destroyed in the animal organism furnishes grounds for ready speculation concerning the possibility that hydrogen is produced by the tissues of the body If hydrogen itself is not produced, there is at any rate a most powerful reducing substance The reducing action appears to proceed according to the laws generally followed by enzymes, that is, it is destroyed by heat, and its activity is greatly influenced by minute amounts of acid and alkali and also by the presence of sugars and other materials The fact I wish to emphasize is that this enzyme continues to exert reducing action both in the presence and in the absence of oxygen Is it not probable that a primary step in metabolism is a reduction with the production of hydrogen which then reacts with hemoglobin? If the supply of oxygen from hemoglobin is adequate for the reducing action of the cells, then phenolsulphonephthalein can no longer be reduced, as it is protected by an excess of oxygen However, if the reducing action of the cells is greater than can be satisfied by the oxygen from the hemoglobin, phenolsulphonephthalein is reduced Fundamentally, therefore, what the phenolsulphonephthalein tests show is the ratio between the rate of reduction and the supply of oxygen in the body Just what the phenolsulphonephthalein shows in any particular case obviously depends on so many factors that it is impossible to localize all the effects in any one organ

a constructive way, one should investigate all these factors and correct whatever is wrong with any of them There is much clinical and experimental evidence that destruction of the pituitary, particularly the anterior lobe, causes a sexual nondevelopment, also that suprarenal tumors cause marked sexual precocity From these data it has been considered worth while to give patients with absence of spermatozoa and no obstructive lesion, and with weak or imperfectly developed spermatozoa, desiccated anterior lobe of the pituitary and desiccated suprarenal gland, particularly the cortex In three cases in which there was complete absence of spermatozoa with very small hard testicles, spermatozoa were not produced in the semen by this therapy In one case, that of Mr D , in which there were few spermatozoa, and what few were present had large heads and no motion, there was a marked improvement following the administration of 40 grains of anterior lobe of the pituitary and 12 grains of desiccated suprarenal daily for one week The second week there was an improvement over the first week The third week the conditions were the same as at the end of the second week At the present time (six months) the condition is approximately normal as regards morphology, the spermatozoa are slightly decreased in number and the sperms have about one half to two thirds of the normal motility and have normal staining reactions As a matter of fact most of our clinical examinations of semen consist simply of determining the presence or absence of spermatozoa, and if present, if they are motile, and do not include careful detailed examination of the rate of movement, morphology, staining reactions and structure of the sperm Clinically these cases are of two types, the cases in which there is absolute failure of spermatogenesis and those that show defective spermatogenesis The first type show azoospermia, but give no history of any testicular disease or injury and on examination show a small, hard testicle with a normal epididymis I have treated these patients with dry anterior lobe of the pituitary and suprarenal cortex, but as yet these dried glands have failed of result I now have one of these patients on six fresh glands daily to see if we can obtain a result with the fresh gland

Early in this work with sterility I was struck with the number of cases presented in which both the husband and the wife stated that they had been examined and were all right On reexamination it was found that the wife was gynecologically normal, but the semen of the husband contained sperm that on careful examination showed numerous defects The motility was much reduced and in some was practically absent The duration of the motility was materially shortened, from a normal of five to six hours down to a few minutes The character of the motility was changed In normal sperm one to two hours old practically every sperm has a progressive movement In these specimens it was noted that many of the sperms had no motion at all, many had a lashing to and fro motion, but progressed very little, while a few only had a slow progressive movement taking as high as thirty-two seconds to cross the one sixth field with No 1 eye piece, as compared to a normal of about eight or nine seconds Likewise the morphology may be markedly altered The following types of semen have been observed 1 The heads may be about twice as large as normal and may take the pink of the Jenner stain, frequently the neck and tail stain blue This picture is frequently given by sperm from the vagina one or two hours after intercourse 2 There may be sperm with a U-shaped tail and normal head and always motionless 3 We have the wryneck sperm usually with considerable motion This type has been found in one of my sac cases practically constantly 4 There may be a large head stained blue with a very thick neck piece and a short tail with slight motion

Motility of the Sperm In examining a specimen of semen as to the motility of the sperm there are several factors that should be considered (1) the time that has elapsed since the semen was ejaculated, (2) the conditions under which it has been kept, and (3) the viscosity of the semen

In a normal semen one to two hours old and kept either at body temperature or around 60 or 70 degrees practically every sperm should be motile, most of them will be progressing, some few will simply be moving in situ or making little progress If the semen is markedly clotted, the progressive motion will be much slower, but the attempts at progression and the movement in situ will be very active As time goes on and the clot thins, the progressive motion will become more and more active, so that a sperm that would take ten seconds to cross the one sixth field will cross it in from six to eight seconds From now on one will notice more and more sperm that have ceased to progress, showing a backward and forward movement only, and even this motion gradually becomes less and less and finally ceases

Coincidentally with these changes, the general rate of progressive movement lessens, and we have in the picture many motionless sperms, many moving in situ, and a few actively progressing In from five to ten hours in normal cases, depending on external conditions, all movement ceases In the specimens which I have considered to be weak spermatozoa, we find many absolutely motionless and at the end of from one to two hours some few only slightly moving, and a few that will have various grades of motion up to approximately the normal In other words, the motility of the spermatozoa grades from normal to those that show absolutely no motion at all The weakest case I have encountered with any movement at all was of spermatozoa which was absolutely motionless at the end of one hour after intercourse, at the end of one-half hour there was some slight motion and at the end of three quarters of an hour there was very slight motion The semen in this case was examined many times and these conditions were always observed, careful account of the time of ejaculation was taken in each instance and the spermatozoa transported in an ideal and constant manner

The normal rate of movement (always timing the fastest sperms) across the one sixth field No 1 eye piece is as follows In semen two and one-half hours old on a cold, rainy spring day at room temperature the speed was 6, 12, 8, 14, 6, 20, 8, 20, 16, 6, 8, 8, 26, 14, 10, 4, 8, 14, 12, 16 seconds The same semen three hours and ten minutes old showed none motionless, few moving in situ, and the following speeds 14, 18, 16, 19, 10, 18, 12, 14, 10, 12, 12, 10, 13, 16, 18, 16, 12, 14 seconds The same semen five hours old shows many motionless sperms approximating one half as many just moving to and fro and not progressing and those that were progressing gave the following speeds 18, 8, 15, 14, 14, 8, 18, 10, 11, 15, 12, 24, 22, 18, 18 The same semen nine and one-half hours old showed two sperms with their tails moving

Cases Showing Decreased Motility Mr B, electrician, denied any testicular disease Examination showed the semen deficient in coagulating properties and the spermatozoa took an average of twenty-three seconds to cross the field at one examination, thirty-two seconds in another

Mr D, first examination, showed a few spermatozoa with large heads and absolutely no motion After taking pituitary gland for about one month examination five months later gave the following findings Spermatozoa numerous, semen 8 c c in amount, specimen one and one-half hours old showed as the speeds of the spermatozoa 18, 36, 10, 14, 15, two hours old 12, 15, 10, 16, 18, 20 In four hours all motion had ceased It was noted with each examination that there were many spermatozoa that were absolutely motionless

Mr T, millinery salesman, small man, not particularly robust Semen one and one-half hours old showed slight coagulating properties The spermatozoa took the following time to cross the field 14, 26, 17, 28, 30 seconds

I have noted that many of these cases of weak spermatozoa show slight malformations of the urethra and testicles, such as hypospadias and nondescended testicles of slight degree

In this connection Cole's experiments with alcoholized sperm are of marked interest, namely, a female rabbit was bred to an alcoholized male and immediately afterward was bred to a normal male, using different breeds so that the young of the two males could be easily identified All of the young born were from the normal male When the alcoholized male was used alone, impregnation took place, evidently the alcohol diminished the motility of the spermatozoa, so that the normal spermatozoa reached and impregnated the ova before the alcoholized sperms arrived, but if the alcoholized ones were given time enough to reach the ova, they were capable of impregnation

Absolute Failure of, or Imperfect Development of, the Essential Female Elements We cannot obtain the ova for direct examination and can only infer from symptoms and signs that ovulation is lacking or imperfect (See under diagnosis of tubal obstructions) Defective development of the uterus can be determined by proper gynecologic examination

Secretions The normal secretions of the vagina are acid and the secretions of the cervix are alkaline Secretions can affect the spermatozoa in two ways either the normal secretions can be changed in such a manner that they are destructive to spermatozoa or the blood serum of the individual may be lytic for the particular spermatozoa that are introduced into the vagina, in the same manner that some blood hemolyzes other blood after the operation of direct transfusion

Destructive secretions can be diagnosed by one of two methods Huhner's cervical test, or by mixing the semen and the secretions from the vagina, cervix and uterine fundus on different slides and observing the motility of the spermatozoa from time to time The cervical test is carried out as follows The couple have intercourse in the normal manner and the wife comes to the office one hour afterward Normally there should be motion in the spermatozoa in the vagina, which are protected from the direct action of the vaginal secretions by the coagulating properties of the semen The spermatozoa that are intimately mixed with the vaginal secretions are practically always dead at this time Spermatozoa at this time obtained from the cervix normally show very active motion If the vaginal secretions are excessively destructive to the spermatozoa, or if the spermatozoa are weak and the secretions are normal at the end of one to two hours, most of the spermatozoa in the vagina are dead To determine the lytic action of blood serum on the spermatozoa, simply mix the blood serum of the wife with the semen to be examined and observe the motility of the spermatozoa from time to time Normally, motion should persist for several hours Alien blood serum kills spermatozoa in a few minutes In one of my cases blood serum of the wife killed the spermatozoa of the husband in a few moments, whereas controls in other serums showed the spermatozoa to move normally and other spermatozoa in the wife's serum moved for several hours This patient was treated with antispermatoxic serum prepared after the method of Metchnikoff As yet there has been no pregnancy Excessive acidity of the vaginal secretion is treated by an alkaline douche or by direct uterine insemination

Treatment of Weak Sperm Cases As the vaginal secretions normally are quite destructive to spermatozoa and as the distance from the uterine fundus to the fallopian tube is much less than from the vagina to the tube it seems rational to think that if these weak spermatozoa were placed directly into the uterine fundus they would have a much better chance of reaching the ovum and impregnating it than if they are thrown free into the vagina, as in normal intercourse, consequently, the best treatment for these weak sperm cases is the direct injection of the spermatozoa (uncontaminated by mixture of vaginal secretions) into the uterine fundus The best time to perform this operation is a few days before or a few days after the menstrual flow If done before, time should be allowed for the spermatozoa to reach the fallopian tubes before the menstrual flow commences If performed after the menses, the sooner after the cessation of the menstrual flow the better For this procedure it is necessary to obtain the semen as free from bacterial contamination as possible, hence one instructs the husband to thoroughly wash the penis with soap and water and thoroughly clean the folds of the preputial cavity The condom is rolled up and boiled and then applied to the penis After intercourse the condom is removed, a knot tied in the top and it is placed in a Dewar flask, corked and brought to the office In the Dewar flask the spermatozoa should be very actively motile at the end of two to three hours

The patient is now placed on the table in Sims' position, the cervix pulled down, the impregnating catheter passed for a distance of 1¾ to 2 inches into the uterus and then from 0 1 to 0 5 c c of semen are injected into the uterine cavity The catheter is withdrawn, the patient rests for ten or twenty minutes and then can get up and go home

CONCLUSIONS

Many cases of sterility attributed to the woman are due to weak spermatozoa

This type of case can be diagnosed by careful examination of the semen, as has been described in the foregoing

The cause of sterility is as often in the male as in the female, if not oftener

Treatment depends entirely on the cause

Obstructive cases, male or female, are operative

Weak sperm cases would indicate direct uterine insemination and glandular therapy, diet, modes of life, etc

Secretion cases necessitate appropriate therapy to check or modify the destructive secretions

Nonproduction of the essential elements, namely, spermatozoa or ova, would indicate glandular therapy

---

ABSTRACT OF DISCUSSION

Dr W C Quinby, Baltimore We know little about the physicochemistry of spermatogenesis, and, as suggested, the question of the relation of the chemical environment to motility of the spermatozoon is a very important one We may learn in the future that by changing either the reaction or the viscosity of the surrounding medium, it may be possible to prolong the life and activity of the spermatozoa My own experience with sterility has been confined almost entirely to the mechanical or obstructive type, and I should like to mention, besides those obstructions which Dr Lespinasse has outlined, some instances in which the obstruction to the seminal passages is either in the ampulla of the vas, or even possibly in the ejaculatory duct I am sure that we are going to be able in the future to perform various plastic operations in these regions with a fair chance of restoring patency In regard to weak motility of the spermatozoa, or their absence without previous disease as a cause, there is in the literature a great deal which speaks for the importance of the so-called ductless gland therapy There have been several very suggestive observations in regard to infantilism in school boys Some of the big English schools have been tabulated, and out of several thousand boys those showing tardy puberty were found to be very markedly benefited by the administration of thyroid extract Its use is purely empirical, but in these cases thyroid extract caused descent of the testes and the normal development of those manifestations which we call the secondary sexual characteristics which had been lacking previously

Dr H L Sanford, Cleveland I have not studied the pathology of the semen as thoroughly as has Dr Lespinasse I have done some plastic work on dogs, but I have never tried Dr Lespinasse's sack operation I would like to ask Dr Lespinasse to give us a little of his technic of uterine insemination I have tried it in several cases, and in two or three instances pregnancy has resulted I do not know whether it was a result of my work or whether it was Providence

Dr A L Wolbarst, New York The genito urinary man who is treating sterility in the male ought also to know something about the sterile woman in the case That is to say, it is not enough to know that a man has sperm in his emission He must have more than that He must have a sperm that will survive the vaginal secretion, and that is one of the things we overlook when we examine a specimen in a condom I have examined any number of specimens in condom, and while I find that the spermatozoa may be apparently normal, when I study that same spermatic secretion in the vagina of the woman, the behavior of those spermatozoa is very different Spermatozoa may survive in a condom in a warm temperature for five, six or eight hours, and the spermatozoa of the same person, when the secretion is very acid, may not survive in the vagina more than half an hour or twenty minutes or ten minutes They vary considerably I examine the vaginal and cervical secretions before coitus in order to determine whether they are acid or alkaline, then I examine the spermatic secretion immediately after coitus, ten minutes after coitus, twenty minutes after coitus, and an hour after coitus and the amount of information obtained in these cases is sometimes startling You will sometimes find very active spermatozoa soon after they are deposited in the vagina, but within an hour the great majority are dead The inference to be drawn is very clear, that the man is not at fault—or rather, to put it another way, his sperma are not at fault, because they are deposited in the wrong kind of vagina I imagine that is why it happens that a man and woman may be sterile when living together, and then in subsequent marriages both the man and the woman may be fertile, because the spermatozoa are deposited in the proper soil Just what effect the vaginal secretions have on the sperm is not clearly understood Broadly speaking, a very acid vaginal secretion destroys the sperm, but how to make an acid vaginal secretion alkaline the gynecologists do not seem to know They say if you will irrigate with sodium bicarbonate it will make the secretion of the vagina alkaline I find that that is not at all effective The vagina is not a test tube, any more than the male urethra is a test tube, and something must be done by the gynecologists to prepare the soil for the spermatozoa by restoring the acid vaginal secretion to its normal character Probably in the normal case the spermatozoa have sufficient inherent vitality to overcome the hyperacid secretion, or better still, in the normal case they are deposited right in the mouth of the cervix and thereby escape the vaginal secretion entirely In these weak cases their action must be accelerated by improving the secretion of the vagina. The second point that is often overlooked in connection with sterility is this In doing the Martin operation of the epididymovasotomy we are apt to place too much dependence on the finding of the spermatozoa in the testicle Assuming that you are ready to make your anastomosis, you will find very often that the vas deferens itself is choked up with cheesy secretion undefinable under the microscope, and which I understand Dr Martin himself has observed but has been unable to determine the nature of I have found the vas occluded so that it has been absolutely impossible for a fine filiform to pass into it for any appreciable distance I do not know that this has ever been studied, nor do I know how it can be determined previous to operation But I do know that in trying to pass a probe or in trying to inject argyrol from the point of anastomosis to the vesicles we fail because of this cheesy stuff, and at the point of incision you can scoop it out of the vas with a fine spoon The thing to do in these cases would be to try to curet the vas deferens and empty it of this substance if it could be done

Dr Charles M McKenna, Chicago The question raised by Dr Wolbarst can be answered in the following manner Strictures of the vas can be treated in the same way that strictures of the urethra are treated, viz, by dilation This can be done by making a small incision in the vas below the external inguinal ring and passing a fine piano wire through the narrow portion of the vas until the vas has reached its normal capacity If necessary the piano wire can be left in the vas from five to fourteen days By this time, the lumen will be of normal size I also believe that this same treatment can be carried out in strictures of the fallopian tube when the woman is sterile I have sounded the fallopian tube and women have become pregnant afterward, while in the case of men, living spermatozoa have been found when they were sterile before

Dr J Leland Boogher, St Louis Sir Henry Thompson fifty or seventy-five years ago succeeded in producing a living English lord by injecting the uterus of a woman after copulation I believe it to be the duty of every genito-urinary man to examine the woman in these cases where sterility is pronounced and the desire for children is great It is not always possible for the uterus to be in a position to receive the spermatozoa, even when they are living and motile, which depends on the prostatic secretion Displacements of the uterus frequently prevent conception Secretions are accumulated in the uterus that are antagonistic to the development and growth and inception of the spermatozoa

Dr Louis E Schmidt, Chicago It is practically a weekly occurrence for me to see some one who is unable to have children Only recently I have seen several individuals of unusual physique and manly appearance, with absolutely no history of venereal disease In fact, they had never had intercourse previous to marriage Both these gentlemen were examined by our foremost physicians previous to marriage and pronounced absolutely well and fit for marriage I am under the impression that the general medical man does not take this functional condition into account He simply looks them over in a general way, as far as medical matters are concerned, and advises the individual to get married After he has been married a few years and there is no offspring there is always trouble I can recall numerous instances like that In connection with the examination of semen I am not in accord with the statement that, in the absence of spermatozoa, most of these cases will fall into the so-called obstructive type I can recall offhand dozens and dozens of cases in which I am absolutely positive no obstructive condition ever existed, and where the elements present were practically only prostatic in character I am under the impression that in all those instances there is some change or some cause for the lack of formation of the spermatozoa and in these cases up to the present time treatment of all kinds has been of no avail For the past four or five years or longer I have tried these different methods, but with absolutely no sign of change in any of these cases

Dr. V D Lespinasse, Chicago In reply to Dr Wolbarst I would say that the spermatozoa are protected from the vaginal secretion by the physiologic clotting of the semen, and not, I think, by any change in the reaction of the vaginal secretions The semen deposited in the vagina clots around the cervix, forming a sort of cup around the os, and from there the spermatozoa get into the cervix and into the uterus In cases in which the spermatozoa are intimately mixed with vaginal secretions the spermatozoa are killed quickly as a rule in one hour, but if you obtain a mass of semen and get the spermatozoa from the center, you will find that they will be normally motile even two or three hours after intercourse The yellowish white material that I spoke of I have observed in the vas several times The first time I saw it I thought it was normal sperm It is very deceptive When the vas is exposed it appears as if the vas was distended with normal sperm When you put this material under the microscope you see little globules that look like fat, but they do not take the sudan III and osmic acid stain Just before leaving Chicago yesterday I submitted some of my slides of this material to Prof F R Zeit, and he was not willing to express an opinion as to the exact character of these globules He would not say it was debris, but thought it was some degenerative product When you find this material you can be sure there is an obstruction further down in the vas and the material itself is not so thick but that it will come through on intercourse In regard to the technic of uterine insemination, there are two or three points about it The first is you cannot inject very much into the uterus The second is, you must use a very soft and very small catheter so that you can deposit not to exceed five or six minims, better about three, in the uterine fundus If you do not have a small catheter you will not deposit any semen in the uterus or you will deposit too much, and the woman will have a very severe colic Before insemination the presence and motility of the spermatozoa should be determined We have tried to standardize this work on an hour Let the couple have intercourse at home, and then get right up and come to the office It is remarkable the difference in the motility of the sperm that you will find Just recently I had a case in which I examined a woman who as a young girl had had a tuberculous peritonitis She is a strong and healthy woman now The husband is a healthy man with absolutely normally movable sperm There was a striking difference in the motility of the sperm taken from the vagina and those taken from the cervix at the end of an hour Those taken from the vagina were barely moving, while the cervical ones had an absolutely normal motility One little by-product of this work is the length of time of pregnancy We have had one baby now from this work, and the baby was born 280 days after the insemination, and that checks up with most of the literature of the cases in which they could check it from one intercourse—it runs from 270 to 290 days

---

Need for Improvement in Care of Pregnant Women—According to S G Moore (*Med Press and Circular*, Nov 15 1916), who advocates the notification of pregnancy, mothers are dying in excessive numbers just as children died and still die in excessive numbers from preventable causes The majority of them do not come under the care of a duly qualified and legally registered medical practitioner until their condition is desperate, and until the opportunity of taking measures to prevent catastrophe is overpast. Pregnancy cannot be concealed, and ought not to be concealed, whether it be legitimate or illegitimate, and since it cannot be concealed, what valid objection is there to comply with a provision which has for its sole and exclusive object the welfare of the woman and her baby ?

THE OPERATIVE TREATMENT OF CRYPTORCHIDISM *

EDWARD L KEYES, Jr, MD
AND
DAVID W MacKENZIE, MD
NEW YORK

The object of this communication is not to discuss the propriety of attempting to place the retained testicle in its proper place in the scrotum, but simply to describe in detail the method we employ to achieve this result The operation is essentially that described by Bevan, but we feel that many of its details have never been thoroughly discussed, and it is our purpose to describe these Such a description appears particularly opportune, since we are convinced that practically every testicle can be placed in the scrotum if the operation is carefully performed Several recent publications describing series of cases of which as many as 30 per cent have resulted in leaving the testicle within the abdominal cavity seem to call for some such detailed description

Let us preface our description with a few statements that appear to us axiomatic, and on which we justify the employment of an operation

1 The testicle retained within the abdomen is doubtless much more liable to teratomatous change than the normally situated testicle The testicle retained in the inguinal region perhaps shows a similar though lesser liability to malignant disease

2 Yet we find no evidence that the testicle which has been placed in the scrotum by operation is unusually subject to teratoma

3 The retained testicle has often lost its spermatogenetic function either by congenital deformity and obliteration of the epididymal tube, or by atrophy of the spermatogenic elements in the testicle itself Such atrophy is not likely to occur before puberty in an organ otherwise normal and with normal epididymis only

4 Hence there is every reason to operate at about the time of puberty in order to forestall atrophy If the operation discloses grave deformity and separation of the epididymis from the testicle, the occlusion of the duct may be taken for granted Yet this is no reason for not proceeding with the operation, since the testicle is doubtless safer from teratomatous malignant change and is certainly more decorative when in the bottom of the scrotum

5 Almost every retained testicle is associated with either clinical hernia or with a pouching of the peritoneum, which predisposes the patient to hernia The operation thus indicated for the cure of hernia is somewhat prolonged but not gravely complicated by the effort to replace the testicle in the bottom of the scrotum

6 The safety of the operation is attested not only by our own series of thirty-three operations with no deaths, but also by similar statistics from other authorities

7 Unless operation is called for by grave hernia at an early age it is safer not to attempt the procedure much before puberty, for the vessels are so small and delicate that they are likely to be torn unless the operator is unusually expert

---

* Read before the Section on Genito-Urinary Diseases at the Sixty Seventh Annual Session of the American Medical Association, Detroit, June 1916

TECHNIC OF THE OPERATION

The skin incision is made as for inguinal hernia, extending obliquely from a point over the internal adbominal ring to a point about 1 inch below the external abdominal ring, the incision lying parallel to and about a finger's breadth above Poupart's ligament

As in the operation for hernia the dissection is carried down to the external oblique aponeurosis, which is then split, thus opening the inguinal canal Until this step has been made no attention is paid to the testicle, for any effort to free this is likely to result in mixing the operator up in a mass of adhesions

The inguinal canal having been opened, the cremasteric fibers lying over the contents of the canal (cord, testicle, hernia) are picked up and divided between two thumb forceps

Working within the fascial layer inside of the cremaster the contents of the cord are then separated and delivered as in the operation for hernia

The hernial sac is now sought for, in the upper part of the canal if necessary, opened and separated by blunt dissection from the spermatic cord

The testicle is now freed from the gubernaculum and other attachments below it, leaving it attached to the patient only by the spermatic cord

Now comes the delicate part of the operation, the lengthening of the vas and vessels In a minority of cases this can most readily be done by treating the spermatic cord as if one were about to operate for varicocele or for division of the vas First, the muscular and fascial compartment in which the pampiniform plexus lies is incised longitudinally and the veins picked out Then the smaller compartment, in which lies the vas with its vessels, is similarly opened and the vas picked out The spermatic cord is now represented by three separate bundles, the pampiniform plexus, the vas and its vessels, and the musculofascial envelope This last is divided and its ends carefully stripped back over the vessels and vas, the exuberant tissue being cut away This dissection is carried with especial care up toward the abdominal cavity until the point is reached at which the vas distinctly separates in its intra-abdominal course from the pampiniform plexus It will now usually be found that there is ample length of spermatic cord to permit the testicle to descend well into the bottom of the scrotum without any tension whatsoever

Certain exceptions may be noted, however, as follows

1 The younger the patient and the smaller the testicle, the less developed is the cord likely to be and the more intertwined with muscular and fascial fibers, so that in such cases (and they constitute the majority) it is impossible to make a clean separation of the vascular elements from the fascial capsule without tearing many and perhaps all of the vessels It will be found in such cases that fascial separation by snipping may be made here and there along the vessels and that a great deal of slack may be obtained by separation within the abdomen

2 If the testicle is originally found near the internal ring or within the abdomen, it is usually necessary to divide the pampiniform plexus, although atrophy will doubtless result from this, in order to bring the testicle down to the bottom of the scrotum

3 If the testicle is at or near the external abdominal ring the slack obtained in the veins is usually greater than that obtained in the vas, so that there is no reason to divide the pampiniform plexus

4 If, in spite of a deep dissection within the pelvis, the vas remains too short, about 1 cm may be gained by displacing it to the inner side of the internal epigastric vessels It has been suggested that the vessels be cut for this purpose, but we have found it perfectly feasible to perforate the fascia to the inner side of the internal epigastric vessels without cutting them, and to slip the testicle through the opening thus made As far as we are aware no direct hernia has resulted from this procedure

5 Retention of the arterial supply is of utmost importance, and it will sometimes be found that the artery of the vas short circuits, as it were, a loop of the vas itself, so that in order to save the vessel we must omit the unfolding of this loop

6 In four cases all of the vascular supply of the testicle was apparently destroyed, only the vas remaining to connect it with the body Yet in only one of these cases did sloughing result The others were considerably atrophied already and there is no evidence that they atrophied any further

The cord having thus been lengthened, the tunica vaginalis, which has doubtless already been opened, is inverted as for the operation of hydrocele

With two fingers the scrotum is opened down to its very base for the purpose of receiving the testicle This simple procedure would seem scarcely worth insisting on did we not know that one of the most experienced hernia operators in New York City has confessed that he has in the past placed almost 50 per cent of his retained testicles in the thigh instead of in the scrotum Apparently his surgical modesty was such as to forbid him from looking to see where he was putting the gland The dissection of the scrotum must be carried rather toward the perineum so as to get to the bottom of the sac and deeply enough so as to open the fascia right to the skin

The scrotum is now inverted on a finger so that it is turned inside out and brought up into the inguinal incision With a straight needle and a fine suture of chromic gut the testicle itself is then sutured to the bottom of the scrotum Two precautions are here necessary In the first place the suture must be placed in the testicle itself, for if the surrounding fascia is sutured there is so much laxity that the testicle may not be drawn down into the scrotum It is obviously improper to suture the epididymis to the scrotum for fear of obstructing the excretory duct, whereas a suture in the testicle itself does no harm The second precaution is to avoid very carefully any torsion of the testicle

With the finger withdrawn, the testicle enters the scrotum and is pulled down into place There it should lie without any tension whatsoever at least well below the pubic bone, preferably so low as to be opposite its fellow If the testicle does not lie spontaneously in good position it is our belief that no amount of suturing about the neck of the sack or suturing the testicle itself to the thigh will better the situation

The wound is now closed in the usual manner, beginning with closure of the hernial sac and then passing to closure of the inguinal canal It has not been our custom to transplant the cord as in the usual Bassini operation

It is noteworthy that three patients have come for a second operation, one a personal failure, the other two failures at other hands Each of the three was reduced with no real difficulty although the separation of adhesions considerably prolonged the operation The ultimate result was just as good as that obtained in primary cases

RESULTS

We have operated on forty-two testicles, twenty-two right, nineteen left, nine bilateral The average age of the patient was 19, the youngest was 5, the oldest 33 Five of the patients were between the ages of 5 and 9 years, all had excellent results excepting one operated on in 1907 He was 9 years of age at the time of operation, and both of his testicles were in the inguinal canal They were placed in the scrotum and sutured to the thigh, but they broke away and retracted into the inguinal canal again Eight years later the right one could not be felt, the left one lay near the external ring and was, by our present method of operating, readily placed in the scrotum, giving a good result One other patient, aged 16, had an extremely bad result The right testicle sloughed, the left retracted over the pubes In one other case the testicle is not in good position, being only just below the pubes and in danger of injury All of the other testicles operated on are in excellent position, that is, they hang free in the scrotum, although many of them are rather in the upper part of this sac On the other hand, a few of the testicles operated on are lower in the scrotum than their unoperated fellows

We have three times operated on testicles that have been badly operated on before All three operations were complete successes

Before operation three of the testicles lay in the abdomen, thirteen in the inguinal canal, twenty-three at or about the external ring Hernia was noted in all but eight cases

During the operation the pampiniform plexus of veins was cut to reduce all of the abdominal testicles, one half of the inguinal ones, and 30 per cent of those at the external inguinal ring Most of these operations, however, were performed before we had perfected our present technic With the present technic we have only once had to cut the vessels of any testicle that lay outside the abdominal cavity Including even our earliest cases, however, we claim 88 per cent good results, and no mortality

We have little to say about ultimate results A number of our cases have been followed several years, and we are fully satisfied that a patient whose testicle is in good position a month after operation is safe from any retraction of that organ into the inguinal canal We have no observations of any value on the spermatogenetic function in bilateral cases after operation None of the testicles operated on by us showed, either at the time of operation or subsequently, any evidence of neoplasm

ABSTRACT OF DISCUSSION

Dr John A Hawkins Pittsburgh There is no question that moving pictures such as Dr Keyes has shown illustrating nephrolithotomy and suprapubic cryptorchidism are of inestimable value and will be of more value as they are worked out In Pittsburgh Dr C L Bradford about nine months ago started to take some of these pictures, and kept it up for three or four months I have an idea that he became bankrupt and had to quit The expense is very great It is also rather hard on the operator The lamps used create an intense heat, which is all right for cold weather but in hot weather it is awful

---

DIVERTICULUM OF THE URETHRA*

SIMON ENGLANDER, MD
CLEVELAND

Diverticula of the urethra, whether congenital or acquired, are of very rare occurrence, Ehrlich[1] having reported but seventy cases all told up to and including the year 1908 Haberern[2] three years later conceded that but twenty cases found in literature up to that time were authentic cases of congenital diverticula, the rest being of the acquired type

Of the two cases mentioned in this paper, Case 1 probably represents the acquired type, while Case 2 probably represents the congenital type as described by Grunfeld[3] and De Keersmaecker, who have seen six or seven similar cases and believe they are of the congenital variety These authors have described cases of small diverticula in the bulbous or prostatic urethra which they accidentally discovered during a urethroscopic examination for the purpose of discovering the cause of a persistent urethral discharge There was as in our case, no stricture or other obstruction present, nor was there any history of trauma, and the writers think that they are due to a defect in the urethral groove

Case 1—H W, aged 30, referred by Dr W O Osborne, had a mucopurulent discharge of several years' standing and wanted to know whether the discharge was infectious Externally the genitalia presented no abnormality, no tumors, scars, etc., being evident At about the junction of the membranous and prostatic portion a No 28 F sound met some resistance, but was finally passed into the bladder Cystoscopy revealed bladder capacity good, mucous membrane apparently normal, except at the trigon, where it seemed to be slightly congested The sphincter was regular Anterior urethroscopy, except for a very pale mucosa, was also negative Posturethroscopy with the Wossidlo showed a cavity on the right side in the membranous urethra, about 1 5 cm high by 0 5 cm in breadth Catheterizing this opening did not produce any pus The patient was seen only once and has not been heard of since

I believe that the diverticulum in this case was due to passage of sounds, was a false passage in fact, made while attempting dilation of the stricture

Case 2—H L, aged 32, referred by Dr W G Mussun complained of discharge of two years' standing There were no abnormalities, and no tumor visible or palpable externally Cystoscopy was negative Anterior urethroscopy showed a very pale mucous membrane, studded with many inflamed, gaping morgagnian crypts

Posturethroscopy with the Wossidlo irrigating urethroscope also shows a chronic fibrous condition of the mucous membrane, the colliculus was small and pale Just anterior and to the left of the colliculus, a small cleft presented itself transversely across the urethra, which on treatment with the Geraghty syringe could be catheterized to the depth of about ⅜ inch Its walls seemed rather resilient, as they gave way under the pressure of the irrigating fluid Its capacity was very small, but could not be determined accurately This case was very similar to the cases described by Grunfeld and De Keersmaecker, and later quoted in this paper

The patient was treated by instillations of silver nitrate up to 5 per cent into the diverticulum, and also by anterior and posterior dilations, and cauterization of the morgagnian crypts, but with practically no improvement in his condition

---

* Read before the Section on Genito Urinary Diseases at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

[1] Ehrlich Zur Kasuistik und behandlung der Divertikel Beitr z. klin Chir 1908 59, 193

[2] Haberern Kongenital Divertikel der Urethra Ztschr f Urol 1911 41, 734

[3] Grunfeld Zur Lehre von der Divertikula der Harnröhre Halbmonatschr f Haut. u Harnkr 1915

Congenital diverticula present themselves usually as more of less spherical saclike dilatations of the urethra usually just behind the glans and always on the lower surface of the penis They are occasionally found at the penoscrotal angle, and may vary greatly in size from that of a pea, or they may take in the whole area from the scrotum to the glans penis In a case reported by Hendriksz, the capacity of the diverticulum was greater than that of the bladder The orifice of communication with the urethra may be very large, or it may be so small that no urine whatever enters it

No unanimity of opinion exists as to the etiology of congenital diverticulum of the urethra Voillemier believes diverticular formation due to partial lack of development of the spongy tissue of the urethra, and believes that it is almost identical with hypospadias formation in which there is in addition a defect in the skin De Paoli, likewise, is of the opinion that there is a primary atrophy and therefore an unresisting corpus spongiosum which allows of the dilatation of the urethra The most plausible and simple theory is that of Kaufmann, who ascribes the condition to the failure of the distal and proximal end of the urethra to unite at the time when the urine begins to flow out of the bladder The proximal end of the urethra becomes dilated, and when finally the union is made the dilatation remains as a diverticulum This theory explains very satisfactorily the frequent occurrence of congenital diverticula in the anterior urethra, and as further proof of his theory he cites the fact that the diverticula are immediately behind the glans penis

Dittel believes that diverticular formation is really a dilatation of the wall of the urethra, and attempts to prove this by microscopic findings, which show a mucous membrane identical with that part of the urethra from which it springs He does not consider the absence of the corpus spongiosum as opposed to his theory, as he believes this is easily explained by a pressure atrophy or by inflammation within the diverticulum

Bokay believes that diverticula are simply dilatations of the normal urethra

Of the French school, Dr Durand, quoted by Cabezas,[4] who reports two personal cases, believes that the condition is not one of simple arrested development but is more complex and should be considered as a disturbance of development, for microscopically he found the corpus spongiosum was perfectly formed, though varying in thickness, and covered the entire dilatation of the mucosa, consequently this lining does not form a simple hernia through an opening in the corpus spongiosum

Cabezas further goes on to say that in congenital diverticulum not only is the mucous membrane of the diverticulum continuous with that of the urethra but histologically the structure is the same as that part of the urethra from which it springs

Of American authors S H Watts[5] is the only one who has written extensively on the subject He cites in full all cases of congenital diverticula reported up to 1906, and believes that at least a very fair proportion of them can be explained by some form of obstruction to the urine in fetal life, such as valve formation, as described by Englisch, congenital strictures, narrowing of the preputial orifice and adhesions of the prepuce to the external meatus

Von Grigolow believes that diverticula are due to dilatations of accessory periureteral ducts which are themselves due to partial defects of the genital gutter When these ducts empty at a very acute angle into the urethra, they form valvelike obstructions which are often responsible for considerable difficulty in emptying the diverticulum in postnatal life

Suter[6] too explains the formation of diverticula by some congenital defect in the genital gutter In reviewing the literature up to 1908 he found only four cases which had been carefully examined histologically and presented a similarity in structure The lining membrane in these cases presented a papillary connective tissue layer and a stratified epithelial layer, which resembled the structure of the skin to a marked degree There was no spongiosum present surrounding the sac Suter's personal case presents a like structure, in fact, so marked was the line of demarcation between the tough white wall of the diverticulum from that of the bluish soft unresisting corpus spongiosum that there was no difficulty in separating the two, and removal of the diverticulum presented no difficulty He therefore concludes that from a histologic standpoint, at least, congenital diverticula are not simple dilatations of the urethral wall but must be looked on as epidermal pockets that communicate with the inferior wall of the urethra While he concedes that the diverticula are usually in the anterior urethra and often immediately behind the glans penis, he insists that they communicate with the urethra oftentimes at a point a considerable distance behind the glans, and were Kaufmann's theory correct, the orifice of the diverticulum should be a very short distance behind the glans

Embryologically he explains the defect in this way The urethra takes its origin from the genital furrow which, covered with epidermal epithelium, forces its way into the position which it is to occupy later as the urethral canal This canal, at first partially open, has at this time a communicating bridge of epithelium with the external surface The epithelium of the canal becomes cylindric, that of the communicating epithelial bridge remains squamous Normally the walls of the canal coalesce and become the urethra, and the epithelial bridge is absorbed It is the persistence of this communicating epithelial bridge that Suter believes is the cause of diverticular formation or of dermoid

SYMPTOMS

The first symptom, which is noticed in infancy, usually is the presence of a tumor and a disturbance in micturition Dittel, however, reports a case of a man of 57, whose symptoms had begun but a year or two before, yet histologic examination of the sac led him to believe the diverticulum of congenital origin There is an increased frequency, and as part of the urine is diverted into the sac, a stream lessened both in force and caliber, and as the diverticulum becomes further distended it encroaches more and more on the lumen of the urethra, causing an increased obstruction to the urinary stream The rapidity with which a diverticulum fills depends on the size of the orifice and to some extent also whether the opening is valvelike, with the free edge of the valve pointing toward the bladder In most cases, however, the diverticulum empties itself slowly drop by drop, after the urinary act is completed, and does not give rise to a great deal of trouble unless the sac becomes infected Not infrequently it becomes necessary to empty the sac by manual compression, especially when the opening is very small, or a valve interferes with the emptying of the diverticulum, causing dribbling of urine, and when communicating with the posterior urethra may cause an incontinence Laugier's patient voided normally, but the diverticulum filled first, and then the urinary stream commenced Should infection occur in the sac, the obstructive factors may make themselves much more evident and may become very acute and cause considerable apprehension as to life, or the condition may become chronic and may be the cause of the usual sequel of a long continued urinary obstruction, such as cystitis, hydronephrosis, pyelitis, pyelonephritis, etc Sudden urinary obstruction due to diverticular formation may follow excesses in drinking or in venery

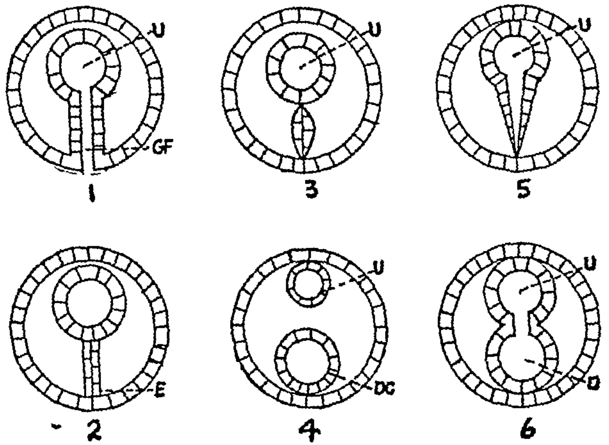
Stone formation is very common in diverticula It is remarkable how many and how large the stones may be and not cause any serious discomfort Grube, quoted by Roith,[7] reports a case of diverticula containing 182 stones In the same paper the author describes his own case of stone in a diverticulum weighing 125 gm and measuring 6 by 5 5 by 4 5 cm, which to the patient's knowledge had existed since earliest childhood, and up to two years previous (he was now 36) had caused him no trouble whatever A soft rubber catheter, 20 F, passed by the stone with ease, and except for a little dribbling, for two years past, there was no interference with the urinary stream It is sometimes of interest to know whether the stone is the causal agent in diverticular formation or vice versa



Abnormalities in the development of the genital furrow *U* urethra *G F* genital furrow *D C* dermoid cysts *D* diverticulum

Goldberg[8] reports a case of persistent gonorrhea which was finally cured by lavage of a diverticulum the size of a hen's egg in the perineum The patient may first become aware of the diverticulum when, during an acute gonorrhea which is apparently cured, pus may be expressed at intervals from the urethra and with no reference to the length of time the urine was withheld, or to the time of day, and disappears just as quickly at it came Occasionally with irrigation under pressure with a Valentine syringe, some of the irrigating fluid may be forced into the diverticulum and cause a tumefaction

DIAGNOSIS

This is usually easy, for the patients usually come with a characteristic history, that is, the formation of a tumor on the ventral surface of the penis during micturition which gradually decreases in size after the urinary act is completed Occasionally the swelling is not noticed until infection, whether gonorrheal or otherwise, sets in Another method is to empty the bladder of its urine, and as the catheter is withdrawn and its eye is opposite the opening of the diverticulum, there is a sudden gush of urine as the sac empties itself Endoscopic examination, especially under water dilation, will often reveal the opening of the diverticulum A congenital diverticulum, too, will give some history of urinary disturbance, such as dribbling, straining or even complete obstruction since early infancy or childhood

The etiology of acquired diverticula is varied and may be due to one of many diverse causes Dilatations may form on the proximal side of strictures or at the site of postoperative scars Stagnation of urine may occur, and the weakened unresisting wall may give way, and form diverticula

Injuries to the urethra, whether accidental or operative, as also fistulas, retention cysts, hematomas or abscesses which burst into the urethra, may be the cause of the formation of diverticula In the male, retention cysts of Cowper's ducts or abscess formation of Cowper's glands, or chronic inflammatory conditions of the mucous follicles of the urethra, or the bursting of dermoids into the urethra are the most frequent causes It is evident, therefore, that acquired diverticula may be situated anywhere in the urethra, contrary to the congenital, which are practically always in the anterior portion of the canal

Careless instrumentation, followed by more or less urinary infiltration, abscess formation, and finally formation of diverticula, is the sequence of events sometimes experienced by the careless worker in the genitourinary field

In the same manner, falling astride the perineum may cause formation of diverticula first by secondary stricture formation and diverticula formation behind it, secondly by breaking down of a hematoma and the rupture of the abscess subsequently formed into the urethra, or thirdly by leaving at a traumatized area a locus minoris resistentiae and consequent dilatation and diverticular formation When calculi obstruct the urethra, they may be an etiologic factor

According to Watts, in diverticula formed behind strictures, the lining mucosa is always inflamed, often even destroyed, this being due to the hard, friable, almost nonelastic nature of the wall of the urethra behind the stricture When the diverticulum is due to an abscess formation or following the rupture of a cyst, the lining membrane is either granulation or scar tissue The mucous membrane of the diverticulum behind a stone is usually smooth and well preserved In all other respects the acquired resemble the congenital diverticula, that is, in their tendency to stone formation, obstruction to urine, etc

TREATMENT

For congenital diverticula this consists if possible in removal of the sac over a catheter in the urethra and the sewing of the edges into the canal so far as possible to restore its normal caliber Should there be any congenital obstruction such as stricture or valves they must be removed

---

[7] Roith Ein Fall von ungewohnlich grossem Divertikel der Harnrohre Beitr z klin Chir 1908 **74,** 267 Aronstam Urethral Diverticula and Cul de Sacs Med Rec New York 1906 **70,** 298

[8] Goldberg Verhandl d deutsch Gesellsch f Urol 1908 **24,** 622

In acquired diverticula, the cause, such as stone, must be removed If the case is a recent one, the removal of the stone will at once cure the condition, while in an older case in which extensive changes have taken place in the wall of the sac, the return to normal will be much slower Diverticula due to stricture formation are cured by dilatation of the stricture, and owing to the fact that there are marked changes in the wall of the urethra, the restoration of the wall to normal is very slow

Diverticula due to rupture of dermoid cysts, abscess of Cowper's gland, etc, can as a rule easily be cured by excision of the offending sac

CONCLUSIONS

Congenital diverticula may be due to any one of several causes, and the theories of epithelial rests advanced by Suter, the theory of defect in or weakened corpus spongiosum as advanced by Kaufmann and others, or the theory of congenital obstruction as advanced by Watts are in the main correct, the various authors encountering a case or cases that they believe prove their contention

Diverticula may be the cause of persistent urethral discharge, whether specific or otherwise, and sometimes when infected may become a menace to life, may cause serious urinary obstruction, cystitis, pyelitis and pyelonephritis

While diverticula of the urethra are much rarer than bladder diverticula, and can usually be recognized easily, there are some cases in which there is no tumor evident, and only a casual urethroscopic examination or one for a persistent discharge will discover it [9]

ABSTRACT OF DISCUSSION

Dr F W Robbins, Detroit Through the kindness of Dr MacGowan I recently saw an interesting case of diverticulum of the urethra This patient had been treated for stricture of the anterior urethra The young man had never had any venereal disease whatever, and had been under the care of an irregular physician for some little time The interesting part was that his symptoms were those of severe stricture of the urethra to the extent that he was obliged to wear a rubber blanket at night to keep the bed from getting wet We found the diverticulum about an inch from the meatus After incising the diverticulum and gradually dilating the urethra up to 28 the symptoms subsided The man had been a great sufferer mentally, but entirely recovered after a diagnosis had been made and proper treatment instituted

Dr Arthur B Cecil, Los Angeles I had thought that diverticula of the urethra were rather infrequent until I heard the discussion of Dr Englander's paper On account of the supposed rarity of the condition the following case might be of interest A man thirty-six years of age was seen by me in consultation with Dr McNab, of Los Angeles He complained of having a stricture and was in severe pain due to retention of urine A silver catheter was passed into the bladder with ease and emptied about 800 c c of urine, but as the catheter passed through the bulbous portion of the urethra there seemed to be pressure against it Examination of the scrotum showed a rounded sac about as large as an egg which fluctuated on pressure On turning the beak of the silver catheter downward it could be passed into this sac in the scrotum and when pressure was made on the sac it emptied through the catheter about 80 c c of cloudy urine The opening of the diverticulum was just back of the external sphincter muscle

Dr David W MacKenzie, New York About a year ago I reported a case of double urethra with a review of the literature There is no doubt that some of these cases are typical diverticula, but many of them are misplaced periurethral glands with dilated ducts, small paraurethras with one or more openings into the urethra, and the complete double urethas ending in blind pockets The patient I had last year had a stone in this canal, and when the stone was removed, he started passing his urine through it He came to our service to have the sinus closed up On opening the sinus we found a double urethra extending from glans to membranous urethra which we removed en masse I do not think we can catalog the congenital diverticula as belonging to any one class They come under true diverticula ducts of misplaced lobes of the prostate and periurethral glands and double urethras

Dr Charles M McKenna, Chicago Some of those cases are overlooked in the diagnosis I recall a patient, a man about 27 years of age, who came to me for advice regarding marriage within the next year He gave a history of gonorrhea of about two years' standing He had a hypospadias with an opening about one fourth of an inch back of the meatus I noticed on examination of the urine that the first glass was always cloudy and filled with pus while the second glass was clear He gave the history of being treated for about two years and could not notice any change I noticed after irrigation that I could expel pus from the urethra by running my finger along the posterior wall One day I noticed that the urethra was enlarged at one particular place and on pressure I was able to expel about half a dram of pus It contained gonococci The patient was sent to the hospital and the diverticulum cut down on and ligated off, the mucous membrane was examined It was found to correspond with that of the urethra and gonococci were found in the pus of the diverticulum

Dr Simon Englander, Cleveland I think that the acquired diverticula are a great deal more frequent than the congenital For this reason I think it depends on one's conception of what a diverticulum is as to which is the more frequent Just before I came here we had a case in the dispensary The man had had an operation for a bulbomembranous stricture You could with the Wossidlo irrigating cystoscope, as well with the Buerger cysto-urethroscope, see a scar in the membranous urethra The posterior urethra was considerably distorted Back of the colliculus was an overhanging shelf and under that a diverticulum Perhaps some would call that a diverticulum and others would not We did Since preparing this paper I have seen five or six of these cases, all of which I think were acquired rather than congenital, because there is a history of something having happened, traumatic or otherwise, and then some of these patients presented other symptoms which strengthened our opinion that etiologically the diverticula were acquired As to the question of cure of diverticulum, unfortunately I have not had an opportunity to do any operative treatment My treatment up to the present time has consisted of silver nitrate instillation I admit I have not had much success

CONCEPTIONS AND MISCONCEPTIONS IN PSYCHANALYSIS *

TRIGANT BURROW, M D, PH D
BALTIMORE

Not infrequently a discussion purporting to relate to a given subject expresses nothing more than the unsophisticated views of the speaker concerning some notion or other which he mistakenly conceives the subject to be Perhaps no theme has suffered more from the disfigurements of these naive tendencies than psychanalysis, so that one does well to distinguish between psychanalysis and rumors of psychanalysis

The truth is, psychanalysis labors under the grave difficulties surrounding any subject which offers us an entirely novel point of interpretation, and far more formidable than the barriers of novelty and strangeness is the fact that psychanalysis is a method which is essentially revolting to our conventional social consciousness, entailing harsh incriminations from which we would prefer to turn away It is a therapeutic procedure which our moral conventions hold in natural repugnance, it is an unpleasant discipline that thrusts before us those things which we dislike to look on But if the theory on which the method rests is correct, such an inbred antagonism to the precepts of psychanalysis is of the very essence of its thesis, for psychanalysis, rightly understood, is a method of treatment based on the recognition of a psychic conflict in the life of the patient arising precisely from his inherent revulsion against the artificial inhibitions which are imposed on him under the constitution of society The conflict is therefore a social one

It would seem, then, that we all have within us the elements of the neurotic diathesis, that the difference between the normal and the neurotic is more a matter of circumstances than of constitution, that the interval between the two is proportional rather than generic

If, therefore, psychanalysis, unlike the gently conciliatory procedures characteristic of other forms of psychotherapy, is a method whose specific task it is to lay bare the pious devices through which we seek to evade life's sterner verities, we shall very naturally incline to resent it as an impertinent intrusion Indeed, it requires no small measure of courage to view with equanimity the unwelcome factors which psychanalysis thrusts before our eyes

It is, then, because of the essential significance of psychanalysis, with its open hostility to the wide social repression of those insatiate biologic demands which belong, broadly speaking, to the sexual sphere, and the consequent affront it offers to our habitual sense of outward reserve, that I am led to utter a warning lest in estimating the value of this inimical method we allow traditional prejudice to distort our judgment

The psychanalytic method, introduced by Sigmund Freud, is, of course, concerned solely with the treatment of nervous disorders In reality the term "nervousness" or "neurosis," as commonly applied, is etymologically misleading, for the morbid condition involved in such psychic disturbances is not neural, it is moral There is question not of a disease of the tissues but of a disharmony of the personality, not of a lesion of organs but of a schism of consciousness We are dealing not with the pathology of the neural elements but with the psychology of the social element as presented in the individual unit, for the disturbances with which psychanalysis has to cope entail in every instance a psychic disharmony based on the individual's relation to the social environment It is an interesting fact that in every psychanalysis there is discovered the influence of some hidden presence who stands in each instance in the closest personal relation to the patient and constitutes the important factor in the production of the neurosis

Before considering, however, the theory, the instruments and the aims of psychanalysis, it may be well to mention certain misconceptions in regard to the method Perhaps we shall gain ground if, before attempting to say something of what psychanalysis *is*, I say a word as to what psychanalysis is *not*

Already I have made intimation of the element of sexuality as an etiologic factor in the manifestations we call neurotic Many will doubtless have heard of the inevitable implication in the psychanalytic method of treatment of the sexual sphere of the patient's life Some probably will either have explicitly heard, or have tacitly gathered, that psychanalysis presupposes the existence in the life of the patient of some secret perversion of the sexual instinct, and that it is the task of the psychanalyst to extort a confession of some such hidden misdemeanor Therefore it is but natural it, from the prevailing trend of current hearsay, it will have been inferred that this new method of psychotherapy proceeds on the assumption that nervous disorders—hysteria, obsessional and imperative states, so-called neurasthenia and psychasthenia—are invariably to be explained by the hidden presence of some abnormal mode of sexual indulgence, and, therefore, the origin of a neurosis, according to Freud's interpretation, is linked with the idea of some species of sexual delinquency

As widespread as this conception has become, nothing could be further from the truth In point of fact, the proposition it maintains is precisely the contrary of that posited by psychanalysis In his "Drei Abhandlungen zur Sexualtheorie," Freud[1] clearly defines the neurosis as the negation of abnormal sexuality He distinctly says that the neurotic and the sexual delinquent stand at exactly opposite poles to one another It cannot be too strongly emphasized, therefore, that the manner in which the patient's sexuality is related, according to Freud's interpretation, to the etiology of neurotic disorders is one which, far from incriminating him, wholly absolves him from the stigma of abnormal sexuality

Still another very prevalent misapprehension is the view that psychanalysis is synonymous with the obtaining of a general confession from the patient

Far be it from me to deny the time-honored psychotherapeutic axiom that an honest confession is good for the soul No one, I think, realizes better than the psychopathologist the undoubtedly remedial effect which follows on the unbosoming of some secret conflict in the mental life But the whole point in the psychanalytic interpretation of the neuroses is that these disorders arise precisely from conditions which render voluntary confession impossible, it being the nature of the disturbing element that it remains of necessity wholly unknown to the patient himself

The typical clinical picture confronting the psychanalyst is that of an individual who, on examination, either reveals no evidence of disease whatever, or else presents a condition which cannot be accounted for by any demonstrable physical lesion Indeed, it is not infrequent that in the opinion of the ablest clinical experts he is pronounced absolutely free from organic disorder Often the patient himself declares that he feels in excellent physical condition, that he eats wholesomely, sleeps soundly, and realizes that he has everything that ought to make a man well and happy, and yet whose every moment is one of unmitigated wretchedness He is perhaps a prey to phobias, obsessions, apprehensions, depressions, sudden and unremitting imperatives, the appalling loss of the sense of reality, to mention the most characteristic symptoms of neurotic states, or he may suffer from digestional disturbance, respiratory inhibition (stammering), muscular contractions, etc, and yet is utterly perplexed to account for the plight in which he finds himself, and completely powerless to furnish any data that might throw light on these abnormal manifestations

---

* Read before the Huxley Society of the Johns Hopkins University

[1] Freud, Sigmund Drei Abhandlungen zur Sexualtheorie Vienna, Deuticke, 1910

In other words, we are in the presence of factors which operate *unconsciously* That is, we have to do with organic effects and reactions which fail to attain the level of conscious perception and which are therefore from the conscious standpoint equally impalpable to patient and physician Let us bear in mind, then, that *the sphere of psychanalysis lies exclusively in the field of unconscious mentation*

With these distinctions before us, I shall try to explain briefly the basic principles of psychanalysis, and to show something of what the method seeks to attain

In many fundamental respects, Freud's teaching, as has been said, marks a wide departure from the hitherto prevailing view as to the interpretation of neurotic states [2]

In the first place, Freud ascribes all neurotic disorders to the existence in the patient of wishes which are unrecognized, that is, not directly envisaged by him Wishes of this unpremeditated character he subsumes under the term "unconscious," and gives to the realm of psychic activity constituting, as it were, the abode of such unconscious trends, the name of "the unconscious" *(das Unbewusstsein)*

Secondly, he regards the neurosis as a spontaneous expression of the tendency toward the fulfilment of such unconscious wishes Thus he ascribes to the neuroses a purposive significance — a moral import The neurosis contains a motive It embodies an underlying intention tends to supply a void not clearly cognized and defined, because existing outside the precincts of consciousness

Thirdly, the ideas or wishes which thus occupy the sphere of unconsciousness possess the generic character of being invariably such as are ethically inadmissible in the sight of consciousness, so that the psychologic account of the creation of this limbo of the unconscious is to be found in the psychic conflict arising out of the opposition of consciousness to these ethically unwelcome desires and their consequent enforced banishment from consciousness — a process which Freud calls the mechanism of repression *(Verdrangung)* [3] Hence, in accordance with the hypothesis, a psychic conflict, with the attendant repression of the unseemly element, is the basic factor in the production of the neuroses

Fourthly, it is Freud's thesis that all such conflicts as issue in such unconscious repression have their ultimate basis in the sphere of the sexual instinct In other words, psychanalysis posits a sexual *repression* as the essential condition in the etiology of a neurosis [4]

And lastly, the theory assumes that such symptoms as are the expression of a tendency toward the fulfilment of these forbidden trends are but an indirect, cunningly veiled representation of them, that they are substitutions employed by reason of their associative affiliation with the original underlying idea Each symptom is the dramatic portrayal of the repressed wish subjected to a process of modification through the effort of consciousness to evade its real significance The symptoms thus expressive of a neurosis are in each instance the resultant of contrary and opposed psychic trends, and represent in their outcome a compromise between the two

Such remodeled, distorted expressions of the brute, primitive instincts as appear in the symptoms of neurotic disorders, Freud has called the phenomena of unconscious symbolization This unconscious symbolization of instinctive trends whereby is effected the necessary palliation required by the censor of consciousness is the crux of Freud's interpretation of the neuroses

According to Freud, the instinct of reproduction is paramount in the life of the individual Yet the sexual trend is not the simple, unitary, static phenomenon it is generally assumed to be, but, like other factors of evolution, is a dynamic process having its integrative components derived from simpler elements Freud points out that the sensations contributory to this impulse are originally composed of dispersed and inarticulate components, having their seats in various erogenic zones located over the body surface and situated chiefly in the regions composing the body orifices The sensations arising from such erogenic zones are present, he tells us, in earliest infancy, and it is of these scattered, incoherent elements that the characteristic sexual feelings pertaining specifically to the organs of reproduction are later constituted The ultimate attainment of the instinct directly conducive to reproduction consists, then, of a process of integration representing the product of individual evolution Accordingly, there are three possible courses in the development of the ultimate sexual life of the individual

First, the sexual life may take a normal course leading to the gradual absorption, so to speak, of these scattered auto-erotic trends into the resultant allo erotic instinct comprised in the ultimate reproductive quest, and having its physiologic center in the organs of generation In such case we have the integration which results in the individual of a normal sexual life

Secondly, there may be a persistence of the original auto-erotic interests and of the sexual satisfaction attaching to these primary erogenic zones, with failure of the aforesaid integration into the sexual impulse which tends toward the goal of reproduction In this case there are presented the variations of the normal sexual impulse which constitute the *perversions*

Finally, the sexual interest or *libido* pertaining to the different erogenic zones through repression may be deflected into vicarious avenues of sexuality corresponding symbolically to such frustrated interests. Such an outcome epitomizes the mechanism of the neuroses as envisaged by Freud. Of course no rigid line of demarcation separates these three possible developmental issues, but there is among them more or less of interlacement of the characters distinctive of each.

---

[2] Forchheimer Frederick Therapeusis of Internal Diseases New York D Appleton & Co 1913 **4**, 569

[3] Brewer and Freud Studien uber Hysterie, Vienna Deuticke, 1910

[4] It should be explained however that the word 'sexual' as Freud uses it, has a far more general and inclusive meaning than is conveyed by the term as commonly employed Contrary to the specific connotation of conventional usage, the term denotes, with Freud the entire sphere of the primary, biologic pleasure affects

The neuroses, then, represent in a negative way a miscarriage of the sexual instinct analogous to that represented in a positive way in the sexual perversions. Freud's thesis, therefore, is that the neuroses betray an inadequacy in the development of the psychosexual life. This inadequacy marks a regression toward a sexual mode appropriate to an earlier, infantile period and postulates a latent, unconscious fixation of the *libido* on its original, infantile object. Hence the sexuality of the neurotic is hindered, repressed and, as it were, preoccupied elsewhere than with the immediate and contemporary object of sexual interest, and the psychologic situation presented by the patient is summed up by Freud in what he terms the patient's "sexual resistances" (*die sexuelle Widerstande*).

Such is the fundamental idea of psychanalysis in regard to the origin and development of the neuroses. The primary factor in the production of the disorders is the repression of the individual's sexuality due to the ban set on the manifestations of this elemental instinct by the strictures of social and religious conventions. It is the conflict between the forces of artificial culture and those of an inherent instinct of sex, the former imposing the repudiation of sexuality, the latter insisting as resolutely on a due recognition of the basal significance of this elemental factor in the biologic economy. The sexual instinct stoutly insists that it be granted recognition in consciousness, and consciousness, in its narrow intolerance, is as fiercely resolved to debar so unseemly an intruder. The final upshot of the situation is a compromise. It is agreed that the unruly element be admitted to consciousness on condition that it soften its tone and, as it were, adopt conventional apparel conformable to the requirements of adult, social consciousness. It is to this end that the psychic organism assumes the social defense it finds in the elaborate metaphorical usages presented in the patient's "symptoms." For it is only through dissembling that the repressed complex can succeed in evading the anathema of the conscious censor. But, though disguised in consciousness, this discordant, outlawed element still lurks in the unconscious, where, acting surreptitiously, it incites dissension amid the constituents of the personality, impairing its unity and destroying the mental synthesis requisite to the purposes of concerted function.

It is Freud's thesis, then, that the neurosis entails a psychic conflict due to an attempt to exclude from a fit acknowledgment, in consciousness, the biologic factors whose prerogatives are fundamental and inalienable. As has been said, such an exclusion of normal interests from participation in current consciousness Freud calls a *repression*. A psychic repression being the essential mechanism of a neurosis, the question for psychotherapeutics is, How may disorders arising from a psychic conflict, issuing out of the arbitrary and extraneous repression from consciousness of such contraband associations, be remedied? Freud, seeking to give the direct logical answer, contends that disorders embodying psychic conflicts due to repression of elements which have a right to tenancy in consciousness are to be effectually cured only by removing the repression and freely admitting such contingents to their hereditary rights in consciousness.

So much by way of outline of the principles contained in Freud's system of psychotherapy. Now as to the method.

METHOD OF PSYCHANALYSIS

It will be clear from the foregoing that the task of the psychanalyst is to bring into the high light of consciousness the ideas or associations which have been relegated to the recesses of the unconscious. The sole clue, however, to such repressed fancies lies in the symbolic equivalents into which these unconscious ideas have been converted through the process of repression. And the source of such surrogate symbolizations is to be sought in the symptoms themselves, in every spontaneous, unguarded reaction of the patient, and, most critically of all, in the patient's dreams. For it is in the drama of dream imagery, which the mind enacts during sleep, when the sentinels standing guard at the outposts of consciousness grow lax in their vigil, that these harpies of the unconscious most easily escape durance and venture to disport themselves with least danger of surprise.

Here, then, is our opportunity to take the demon of the unconscious unawares. Not that this unconscious ogre, be it remembered, is wont, even in dreams, openly to expose itself, but there are revealed in the creations of dream phantasy traces of its presence whereby it may be tracked to its hiding. This tracing of the repressed interests contained in the ideas lying behind the dream images constitutes the method of dream analysis, as developed by Freud, and it is the analysis of the patient's dreams which is by far the most important resource of the psychanalyst.

In Freud's conception, the actual dream, as revealed to consciousness, that is, the *manifest content* of the dream, is but an enigmatic congeries of psychic images — a charade that condenses in scenic productions a whole mass of related, interconnected meanings or dream thoughts, and it is the latter which constitute the real or *latent content* of the dream. Dream analysis or dream interpretation consists precisely in reaching these concealed fancies and so correlating them in accordance with precepts empirically determined as to render them coherent and significant. To do this it is required that the patient retrace the mental threads out of which he has woven together the elements of his dream tapestry. Such threads are composed of links in interconnected chains of associations, and it is the task of psychanalysis to follow these threads of associations to their source, in order to reach the material out of which the dream images were originally spun.

Such a proceeding is fraught with difficulties, for obviously as the dream creation is precisely the outcome of the effort of consciousness to disguise, and so evade, the real meaning underlying the manifest dream elements, analysis involves a task no less formidable than that of pitting the patient against his own inherent will. It really means setting the patient at cross purposes with himself by forcing him to face frankly the thoughts and wishes which he has perhaps for a lifetime sought to repudiate, that is to say, the ideas which have been ruthlessly debarred entrance into consciousness and which in consequence pursue their career beyond the pale of apperception, manifesting themselves subtly in the symptoms and obsessions characteristic of neurotic states These ideas are one by one readmitted into consciousness and are through this procedure deprived *de facto* of the essential motive of their existence

As the analysis constitutes per se the entire system of psychotherapy introduced by Freud, an adequate account of the psychanalytic method would entail a full description of its technic The technic of psychanalysis, however, is too varied to be susceptible of definite formulation Indeed, the technic of psychanalysis is too intimately bound up with the delicate psychologic *rapport* existing between physician and patient to be separable from it, for each detail of the patient's behavior conveys its own nuance of meaning that is of the utmost import to the psychanalyst

The practical procedure which is followed in the analysis of dreams, however, may be broadly indicated The patient, having repeated his dreams, is asked to relate quite freely whatever occurs to his mind in connection with the different elements of which the dream is composed This method Freud calls that of "free-association" From the ultimate ideas at which the patient arrives at the end of each of the chains of associations leading from the several elements of the *manifest dream content,* the physician is enabled to reconstruct the underlying trend contained in the latent content of the dream and so discover the patient's dream thoughts

The links in the chains of associations do not succeed each other at regular temporal intervals, but frequently the patient halts, showing signs of discomfort and unwillingness to continue It is apparent that in such instances the patient's flow of thought is blocked by resistances, that is, he has come on a trend which he has long put away from him as distasteful, as unfit to hold a share in his contemporary consciousness At such crises, the patient must be encouraged to continue without fear or reserve He is reminded that the self-criticism which interposes itself in the current of his spontaneous associations tends to thwart the course of the analysis and to frustrate the whole purpose of the procedure So when he resumes again the thread of associations, concentrating his attention anew on the reminiscences occurring at the point of interruption, it is usual that he will be brought to reveal some incident or trend of marked significance in his affective life In other words, one comes in such intervals on psychic material which has been submitted to the process of repression and which, with its clusters of associations, constitutes a deterring "complex" in the patient's psychic life

In fairness it must be said that the psychanalytic method of procedure is far simpler to set down in writing than to carry out in actual practice From the very nature of the neurosis, with its repression or rendering unconscious of the most vital trends in the psychic life of the individual, there are, of course, enormous habitual resistances to be overcome To lead the patient to break through this habitual reserve is a task requiring the utmost expenditure of time, patience and ingenuity on the part of the physician, so that not infrequently hours are consumed in arriving at the determination of an objective statement which it would require but a few minutes to set down in writing

Of course the central interest in dream analysis lies in Freud's dynamic theory of dreams Freud teaches that the basic factor in every dream is an unconscious wish fulfilment that whatever the manifest content may be, however foreign apparently to the idea of a coveted purpose, every dream will, on adequate analysis, reveal the presence of a repressed wish How totally dissimilar in their content are the repressed wishes of the unconscious from what we commonly accept as the interests of our conative life, how utterly abhorrent to our ethical sensibilities such latent "wishes" invariably are, what, in short, is the real nature of an unconscious wish, in the sense of Freud, may be gathered only from a thorough study of Freud's dynamic psychology of the unconscious as contained in his major work "Die Traumdeutung"[5] It is here alone that one is enabled to comprehend the very original and revolutionary conceptions on which Freud bases his theory of the unconscious and in which he elaborates the principles underlying his searching study of the biology of mind

Next in importance to dream analysis is the association experiment which Jung of Zurich has adapted to practical psychanalytic application[6] The association experiment is useful chiefly as an instrument of diagnosis and for the purpose of a long-continued study of some specific problem, as the differences of reaction types But it is also most valuable to the student in beginning psychanalysis as a means of obtaining a preliminary survey of the general reaction of the patient and of opening the way toward gaining insight into his unconscious mental processes

The association experiment has three chief advantages First, it affords a *direct* avenue to the patient's repressed interests, second, it offers access to such repressed spheres of affectivity in spite of the patient's own unyielding resistances and, third, it affords us a means of investigation which includes in it the conditions of an objective control so essential to an exact experimental study of the data required in comparative psychologic tests

In arrangement and actuation the association experiment is very simple The idea of the test is this Every word represents for each person a psychologic situation This may have, according to individual circumstances, an accent of greater or less emotional value To say that a word possesses an emotional value is the equivalent of saying that it makes a deep impression on the psychic organism, that is, that it stirs a strong wave of response in the consciousness into which it falls

Manifestly, if the length of such emotional wave may be estimated, we have obtained a measure of the relative strength of the emotional tone represented by it This is precisely the result which is effected by the conditions of the association experiment

A series of words called test words, usually 100, are repeated to the patient, who is required to respond at once with the first word associating itself in his mind with the test word given By measuring with a stop watch, recording fifths of a second, the interval occurring between the stimulus (the calling of test word) and the reaction (the patient's response), a mathematical estimate is given of the relative emotional value of the situation recalled by the test word in question, for the more profoundly the consciousness of the patient is stirred, the longer will be the interval required in order to return to the mechanical routine of response required by the concrete conditions of the experiment

---

[5] Freud *Die Traumdeutung Vienna,* Deuticke, 1910 translation by A A Brill

[6] Jung C J Diagnostische Associationsstudien

Hence, having obtained the length of the patient's probable average of reaction time, any marked excess of this interval indicates the presence of a significant reminiscence, that is, of an underlying complex A marked variation in the length of reaction time is, then, the most important of the complex indicators

A further aid in unearthing the hidden complexes is that of obtaining the patient's "reproductions," that is, having obtained his responses to the series of stimulus words, to test his memory of each of his responses by again repeating the test words In this procedure a wrong reproduction or failure to recall at all the original reaction word is indicative of a complex having been stirred Here again the excess of the affect carries the mind of the patient from the immediate verbal image to some intimately associated impression, and the significance of the reaction word as such is lost in the greater emphasis of the remembrance awakened by it

Still a further complex indicator consists in the successive decrease of the heightened interval of reaction time effecting the three or four immediately subsequent reactions To this species of complex indicator Jung has given the name "perseveration "

The frequent recurrence of the same reaction word throughout the experiment, the assimilation of the test word in an unusual sense, repeating the stimulus word before reacting, replying with more than a single word, offering explanations, etc , are among the many additional indications that a complex has been excited

Such are the chief means affording a clue to the lines along which the analysis may most judiciously direct its inquiry and so contribute to effect the release and thorough ventilation of the repressed affects which are responsible for the inner psychic disharmony

It is thus that the physician succeeds in establishing a synthesis amid the discordant, mutually exclusive elements of the personality It is thus that the psychic tension due to the mental conflict is eliminated and the dissociated elements of the ego are brought together in a simple unitary stream of consciousness

Such is the treatment of psychic disorders by the method of psychanalysis The statement given here affords but the merest hint of the full import of the method This is long and laborious, often entailing in actual practice many months for the adequate analysis of a single case To gain anything like a commensurate idea of the full significance of the psychanalytic method, one must put himself in touch with Freud's conceptions of the unconscious as presented in his writings In his various contributions to the literature of psychopathology, Freud has presented an account of the system of psychology on which he bases his explanation of the essential processes underlying neurotic disorders and in which he defines the rationale of the psychanalytic method of treatment

USES OF PSYCHANALYSIS

While, in my opinion, the discoveries made by Freud through his long and laborious investigations are as sound scientifically and as important economically as any in the history of modern medicine, I do not by any means regard psychanalysis as a universal panacea for nervous disorders, but on the contrary consider it as the particular method of psychotherapy that is most restricted in its possibilities of application,[7] a reflection, however, which is rather comforting than otherwise when we consider the length of time required — frequently, as I have said, as much as an hour daily for weeks and even months — for the adequate analysis of a single case This being true, it seems a fortunate circumstance that psychanalysis is not the suitable method in all cases — that other and simpler methods of psychotherapy are applicable in many types and degrees of nervous manifestations, and even if sometimes unscientific, they are at least effective for the ignorant masses to whom they are applicable

The fact is that psychanalysis is practically adapted to only a few persons, but those few belong, generally speaking, to the most educated classes and are precisely those personalities who, from the nature of the conditions of the onset of a neurosis, are the most sensitive, highly developed and worth while among us, and whose reeducation through self-analysis will be most far-reaching in its influence on the body social

Psychanalysis can never hope to become popular for the reason that it is honest It does not flatter or cajole the patient or seek to appease him with subtle blandishments, on the contrary, it mercilessly thwarts and assails him The mawkish and artificial will find in it little unction for their boredom Psychanalysis offers nothing brilliant or spectacular, but, being a robust, uncompromising method of scientific investigation, it proceeds in the laborious, unobtrusive manner of all earnest research, and is adapted to the needs of only earnest and intelligent men and women

Though lacking in frills, the method is not without its practical compensations One need not be irresistible to be a psychanalyst In psychanalysis "personality" is no asset The method places no premium on the personal charms of the physician

The misconception concerning psychanalysis which seems to me of all the most unfortunate is the view that there exists an inherent opposition between the principles of psychanalysis and those of experimental psychology On the contrary, the psychanalyst of far perspectives can hardly fail to recognize the possibilities of mutual gain in the complementary positions which these two departments of research occupy in relation to one another, nor can he fail to see the opportunity he has in the objective controls of the experimental method for the substantiation of his results Nothing, it seems to me, can more certainly cripple the researches of the psychanalyst than this very fundamental misapprehension

I believe William James once said that when any discovery is newly given to science the cry at first is that it is not true, but that later, as the truth of the new theory becomes manifest, this attitude is replaced by the admission, "Yes, it is true, but *I* discovered it " Now that psychanalysis is entering this latter phase of its career, there begin to appear various bogus psychanalytic procedures which are in truth mere travesties on the original method of Freud, and we need be on our guard against the cunning decoys of such spurious artifices

We shall do well, therefore, to discriminate between psychanalysis as represented in the systematic, laborious, time consuming method of psychotherapeutic research introduced by Sigmund Freud — a method imbued throughout with the spirit and ideals of the laboratory — and the pseudopsychanalytic substitutes which pervert Freud's method to sensational uses Psychanalysis proper is wholly incompatible with the business of medicine The hurrying practitioners who say that they use psychanalysis as occasion arises, as though they kept it on a shelf in bottles, simply fail to understand the first principles of the method, for psychanalysis is not a tablet but a system It is not to be summoned by caprice or expedience but must be acquired by careful study and training, and above all by the exacting discipline of a thoroughgoing self-analysis

GROUP STUDY

A REPORT OF ONE HUNDRED AND FIFTY CASES *

WILLIAM WALLACE BEHLOW, A B, M D
SAN FRANCISCO

In a recent article on group study,[1] Birtch has described the methods in use in the Diagnostic Section of St Luke's Hospital Clinical Club, of San Francisco He has shown the advantage of correlated study in the investigation of patients, and has explained the details of the diagnostic team work Since the publication of that article, numerous inquiries have been received which indicate that this method of clinical study is not clearly understood In order that the profession may understand the character of this work, a brief review of the important features will be presented here

The most important phase of the work is the thoroughness of the examination Each patient is examined by each member of the diagnostic section The purpose of such an examination cannot be clearly appreciated by every one, inasmuch as questions such as the following have been received within the last month One prominent clinician asked, "Don't I do as much for my patients when I call various specialists in consultation?" In answer to that query, it may be stated that in ordinary practice only those consultants are called who, in the opinion of the patient's physician, are necessary to clear some point in diagnosis or treatment It is conceivable that an extraordinarily keen physician may be able to discover every lesion in a patient with or without the aid of other individuals On the other hand, a patient may have early signs of disorder in a certain part of the body, without presenting symptoms of sufficient importance to draw his physician's attention to that region It is not likely, therefore, that a specialist of diseases of that region would be called in consultation From a prognostic point of view, the recognition of such a disorder may be of the greatest importance to the patient

Therefore, in order to eliminate such errors, the members of the diagnostic section decided that each patient should be examined by all the clinicians of the group By this method, an early retinitis, or a beginning ostearthritis of the spine would be recognized by the oculist, or orthopedist, respectively, even though subjectively the eyes and spine were negative Through this plan of investigation, the responsibility of seeking advice does not rest on one individual, for each patient receives the examination of a specialist in the latter's particular domain

To perform this series of examinations, the patient is in the hospital for an average of 100 hours, and during this period is under the direct control of the resident physician of the diagnostic section This enables the section to perform all the necessary tests which are so much a part of medical diagnosis at the present time A daily consultation of all the clinicians is held, and the case is thoroughly discussed from every angle

Finally, after definite conclusions have been reached, a written report of the history, of the clinical and laboratory findings, of the final diagnoses, and of suggestion as to future therapy is sent to the patient's physician, who again assumes full charge of the case

This method of group study has been in existence for almost a year When the work was begun, the diagnostic section had no idea of the many obstacles which had to be overcome, or of the many pleasant surprises which were in store for the members of the section It is my endeavor to present a few interesting facts concerning the first 150 cases which have been investigated by this method

A brief consideration of the histories of these patients is of more than passing interest In an unpublished article, Read has clearly shown that from a careful history one can make a positive diagnosis of the primary or major condition in 53 per cent of the cases The same care in taking a history will make possible a positive diagnosis of the secondary conditions in 41 per cent of cases It is therefore obvious that an accurate record of the patient's past and present history is of the utmost value for the proper consideration of data elicited on examination

In order that there may be no omissions in the record of the past, a printed form for the history was prepared and a definite statement required after each question No such routine could be employed in recording the present illness Therefore a detailed record of the present illness has not been obtained through any set questionnaire Omissions by the historian have been corrected by secondary questioning on the part of the clinicians who examine the patient Through this method few details have escaped the notice of the examining group

A decided advantage to be derived from such a method of recording histories is the ease with which one may determine the frequency of any symptom, or group of symptoms, in some special disease As an example, one may desire to know how frequently night sweats have been present in the past history of patients in whom the diagnosis of tuberculosis has been made Inasmuch as each record contains a statement concerning this fact, one may readily find the answer to such a question A tabular review of the prevalence of each symptom is periodically made, in an endeavor to confirm or correct clinical impressions which have been gained from the literature The results of this investigation will appear at a later date

Turning now to the diagnosis of the case, it has been taught in the past to make as many of the signs and symptoms agree with one clinical picture as it is possible to do While this is still the aim of clinicians, there has been a tendency to overlook pathologic conditions of apparently little consequence, which, a few months or years later, may be of greatest importance to the welfare of the patient How often this is true of patients who have been subjected to surgical procedure is only too well known to physicians

In this series of cases, the major diagnosis has not always followed the prominent symptoms of which the patient complained, but has frequently been more inti-

mately related to the prognosis Such an instance may be cited in the case of a patient who came to the hospital for surgical treatment of a gastric ulcer Before the operation had been definitely decided on, the patient was examined by the diagnostic section Conclusive evidence of peptic ulcer was found, but also definite signs of active pulmonary infection of probable tuberculous origin were obtained In view of these facts, operation was not recommended, and the final diagnosis placed pulmonary tuberculosis first, and ulcer of the stomach second One might go into greater detail in discussing this most interesting phase of the work

From a tabular study of these 150 cases, it is interesting to note that of the forty-eight surgical cases, only seventeen patients were operated on immediately after the diagnosis was made Of the remainder, three were recommended for operation without further treatment, and for five it was suggested that medical therapy be instituted before operation was performed This is in marked contrast to the usual procedure in the average surgical case

Furthermore, it is of interest to note that the patient's own words, as given in the complaint, conveyed a definite idea concerning the ultimate diagnosis in approximately 60 per cent of the cases as far as the primary diagnoses were concerned

This is of course noteworthy, showing, as it does, the importance of laying considerable emphasis on the actual complaint of the patient In this day of ultrascientific medicine, we are too prone to forget that the patient has come to us for a definite complaint In view of the experience in these few cases, it would certainly behoove all of us to pay more attention to the real troubles of the patient, rather than wander off into the by-ways of medicine in an endeavor to establish some extraordinary diagnosis

Naturally, one hesitates to draw any conclusions from such a small number of cases My associates are convinced that group study is a most interesting and instructive method of practicing medicine, in that it gives the patient what he asks for, it aids the average practitioner, and it creates a desire on the part of the members of the group to enhance their medical knowledge

The best criterion of the success of this method must necesarily be the reports of the practitioners who have sent their patients to the diagnostic section for information concerning the morbid processes of the patients themselves In accordance with recognized principles regarding hospital statistics, the diagnostic section has sent out the so-called follow-up letters, in an endeavor to determine just how well or how poorly the section was doing The accompanying report presents the answers to the letters concerning the cases presented above

A superficial analysis of the report would give the skeptic plenty of opportunity to criticize the principle of this method of investigation When, however, it is realized that thus far only cases which have been obscure in the minds of the patients' physicians have been referred for diagnosis, it is surprising that the results have been as good as they are Two features of the report are worthy of note, without further comment first, 141 cases were satisfactorily investigated, second, in only ninety-nine cases were the recommendations regarding treatment carried out Early in this work, and even now, there are many who are decidedly skeptical Unfortunately, they expect that a correct diagnosis must necessarily result in a favorable prognosis It must furthermore be remembered that many of the cases reported were decidedly unfavorable, prognostically, from the very beginning, inasmuch as the patients came to the diagnostic section as a last resort

Considering these facts, it may be stated that while the members of the diagnostic team are far from pleased with the reports received from the physicians who referred cases, yet with due regard to the circumcumstances attending the patients I feel that the percentage of favorable results certainly proves the value of such a method of clinical investigation

CONCLUSIONS

1 Ten or twelve physicians, each interested in a certain field of human ills, working together, will discover ailments which one physician of more than average ability will not be able to discern

2 The discovery of symptomless disorders may be of the greatest importance to the patient in after years

3 A thorough history will make the ultimate conclusion a matter of considerable less difficulty than if that thoroughness was neglected

4 The keeping of records is an important feature of medical practice, inasmuch as many hard and fast ideas derived from incomplete observations and transmitted from one book to another may be found to be incorrect

5 The average patient will certainly benefit by the group method of consultation

6 The average physician in the majority of cases has thus far placed on this method of investigation his stamp of approval, and it is believed that when the idea of group study of patients is better understood, the majority of physicians will give their hearty approval not only to the principle on which it is founded, but also to the method itself

233 Post Street

THE TREATMENT OF GONORRHEAL INFECTIONS

BY THE INTRAVENOUS INJECTION OF KILLED GONOCOCCI, MENINGOCOCCI AND COLON BACILLI *

HARRY CULVER, M D
CHICAGO

After the intravenous administration of a highly polyvalent gonococcal vaccine, Bruck and Sommer,[1] in 1912-1913, observed striking therapeutic results in gonorrheal complications, especially arthritis, epididymitis and acute prostatitis These results, within certain limits, ran parallel to the severity of the reaction following each injection A specific temperature increase was noted which was higher in gonorrheal than in nongonorrheal patients, hence this method was suggested as a diagnostic as well as a therapeutic agent At this time the entire process was attributed to the production of a specific immune substance, caused by the intravenous injection of the gonococcal vaccine

It has been clearly demonstrated that, in typhoid injections, a nonspecific reaction follows the intravenous injection of colon bacilli, pyocyaneus bacilli, and secondary proteose preparations These substances give results clinically and therapeutically quite like an injection of killed typhoid bacilli

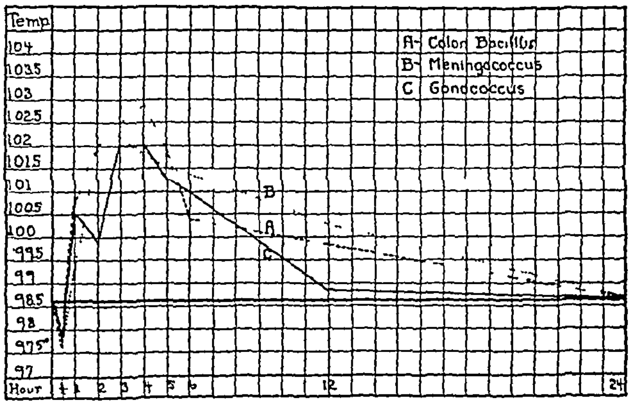

Chart 1—Composite temperature curves following intravenous injections fifty four gonococcal injections in fourteen patients twenty three meningococcus injections in twelve patients, and eight colon bacillus injections in seven patients are represented

In order to determine the degree of specificity, if any were present, following the intravenous injection of gonococcal vaccine, three series of patients suffering from gonorrhea and some complication, such as arthritis, epididymitis or acute prostatitis, were chosen in the order in which they had entered the hospital,[2] no attempt having been made to classify them as to severity or complication The first series was treated intravenously with a strongly reacting dose of gonococcal vaccine, the second series received a similar dose of meningococci, while the third series received a suitable dose of colon bacillus vaccine

The patients, when possible, were kept in bed throughout the treatment, special care being taken to keep them quiet for two days following each injection No local or internal treatment was given for the gonorrheal infection other than an elevation of the scrotum in all instances of acute epididymitis The temperatures were taken and the leukocyte and differential counts were made just before each injection and at regular hours thereafter for the first forty-eight hours

VACCINE TREATMENT

Gonococcus Vaccine—The first thirteen patients were given intravenously 100 million killed gonococci, and the same or slightly varied dose was repeated every fourth or fifth day until treatment was suspended The greatest number of injections given one person was six, most of them received five, while one received but one injection

The injection is followed by a chill of variable severity coming on in from twenty minutes to one hour and lasting from fifteen to thirty minutes This chill may or may not be accompanied by headache, which is usually of short duration and passes away shortly after the chill is over Exceptionally there are nausea and vomiting during the first few hours, but it is never severe and is always transient This occurs always in patients who have disobeyed instructions, by eating heartily within a few hours of the injection

At the onset and during the chill the patient often complains of severe pain in the affected parts Whether this is due to some internal cause or to the unavoidable motion produced by the chill it is impossible to say The pain, however, is variable in different patients and in the same patient at different times

It is usual for the severity of the reaction to decrease following repeated injections, and this decrease is directly proportional to the number of injections previously given In order to maintain a constant reaction with each succeeding injections of gonococcal vaccine gradually and cautiously increased

In two of these patients, both of whom had had numerous subcutaneous injections of gonococcal vaccine, there appeared immediately following each intravenous injection a very transient reaction characterized by flushing of the face, cyanosis, dyspnea, and a tingling sensation over the surface of the whole body These reactions lasted from one to two minutes, after which the patients felt perfectly at ease until the usual reaction appeared in from twenty minutes to one hour This anaphylactic-like reaction may have been due to a partial sensitization from the previous subcutaneous injections Three other patients in this series developed a mild type of a very similar condition on their third intravenous injection, but had none following the first two, or after the fourth and fifth injections

The typical temperature curve following these injections reveals a slight fall during the first part of the chill, followed by a gradual rise, which reaches its maximum in from one to four hours and gradually falls to normal in twenty-four hours The average maximum temperature for the thirteen patients was 103 9 F, the highest temperature being 104 6 and the lowest a maximum temperature of only 102 8

The leukocyte counts during a reaction and following it are somewhat variable Usually there is a mild leukocytosis just before and during the first part of the chill, soon followed by a marked leukopenia, which appears toward the end of the chill A count as low as 2,000 has been observed repeatedly during this stage of the reaction This condition is soon followed by a gradually developing leukocytosis which reaches its maximum in from five to seven hours, and remains moderately high for from twenty-four to thirty hours A return to normal occurs in about forty-eight hours

---

* From the Department of Experimental Medicine University of Illinois College of Medicine

[1] Bruck and Sommer Munchen med Wchnschr, 1913 **60**, 1185

[2] All patients here reported were from the services of *Drs Harris* Simpson McEwen and Stillians of the Cook County Hospital, to whom I wish to express *my thanks for the privileges granted*

The average of the highest counts made in the first thirteen patients was 33,300, the highest individual count being 55,000 The lowest count of one patient was only 22,000 This marked and sudden change in the leukocyte count is due almost entirely to an increase or decrease of the polymorphonuclear leukocytes in the peripheral circulation, their percentage being as low as 50 during the leukopenia stage and as high as 96 during the height of leukocytosis

Meningococcus Vaccine—The second series of fifteen patients was treated with killed meningococci in the same dose and at similar intervals as in the gonococcus series

The reactions as far as could be determined were similar in every detail to those produced by the gonococcus vaccine One instance of a double reaction occurred following the first injection, and one patient developed this condition after two injections None of this series had had previous subcutaneous or intravenous injections The average maximum temperature for this series was 103 5 F, the highest single temperature being 105 2, while the lowest reached only 102 The temperature curves were uniformly like those following injections of gonococci

The leukocyte curve in general likewise followed those of the first series very closely the average maximum count being 27,800, the highest single count was 46,400, while the lowest had a high count of 20,000 The type of cell varied as in the first series One very striking difference was observed between the two series Over one half of the meningococcus series developed a more or less severe herpes of the lips and mucous membrane of the mouth, first appearing in forty-eight hours and remaining for from four to seven days This condition did not occur following any but the first injection, and did not become aggravated or recur when further injections were made in a susceptible individual No such reactions followed the gonococcus injections

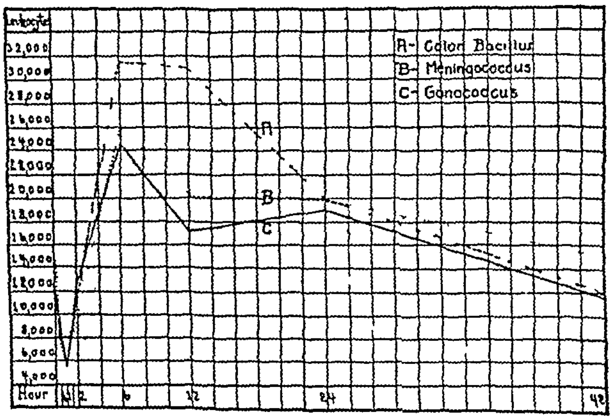

Chart 2—Composite leukocyte curves following same intravenous injections as represented in Chart 1

Colon Bacillus Vaccine—This series contained but seven patients The reactions were in every way like those produced by meningococcus and gonococcus, with the exception that the size of the dose required to produce the same results was very much less At first a dose of 100 million organisms was given, but the reactions were so severe that 25 millions were finally used as the initial dose, this to be increased if necessary to produce the desired results

The average maximum temperature was 104 F, while the average highest leukocyte count was 35,500

There can be no question that the homologous curves representing the reactions produced following the injections of each organism are very similar, as seen in the accompanying charts, however, the curves representing the colon bacillus seem to reach a higher point in both instances, this is due to the smaller number of injections represented in the curve The crest of a curve of this kind is obviously not so high as one representing a single typical reaction, since the time of the maximum temperature and leukocytosis may vary somewhat for different individuals, or for the same individual following repeated injections

As far as therapeutic results are concerned, there is no noticeable difference between the three bacterial suspensions, once the proper dosage is established To produce results therapeutically, a reaction is necessary That is, a chill must occur which is invariably followed by the temperature and leukocyte changes noted above A dose insufficient to produce a definite chill is not followed by so marked a temperature and leukocytic reaction, and clinically no therapeutic benefit is derived At times there may be some fever production and a moderate leukocytosis not preceded by a chill The reactions and therapeutic results appear very distinctly similar for the three organisms used when gonorrhea-infected patients are considered The reactions following injections in nongonorrheal patients are not to be distinguished from those produced in infected patients, nor is there any noticeable difference in the reactions produced here between the three organisms

These observations were made by injecting a series of patients having chronic skin lesions but no history or indication of gonococcal infection The size of the dose required to produce a reaction, the chill, temperature and leukocytosis were alike in every way in the infected and noninfected patients

Twenty-four patients suffering from arthritis associated with gonorrheal urethritis were treated Naturally most of these cases were acute or subacute, but some were of five months' duration and many were of over ten weeks' duration when the treatment was begun

As might be expected, the most striking results were obtained in the acute and subacute cases, the most refractory cases, however, were also in the acute class Those suffering for long periods appear to respond more slowly to the treatment, but fortunately seem to suffer from no recurrences or new joint involvements during the course of the treatment, as some of the more acute cases do All but two of the arthritic patients were completely cured or manifested a decided improvement The length of treatment varied from two days to one month

Unusual effects were seen in three patients with acute arthritis so severe that sedatives were necessary to give them rest for the first two days in the hospital After a single reacting dose in each instance they felt so well that they insisted on getting out of bed, and in three days they walked out of the hospital Two of the patients had effusions in the knee joint, which completely disappeared before their discharge from the hospital. Unfortunately none of these men have been heard from since, so the permanency of the striking results in these instances is not known. The fact that they have not returned to the hospital suggests at least that a recurrence as severe as the original attack is not probable. Equally striking was the following instance:

J. R., a man, aged 28, had been confined to his bed for four weeks with arthritis of almost every joint of both lower extremities. These lesions had come on during the third week of gonorrhea. After the third injection he was up and walking about, and after the sixth injection he was apparently completely cured. He went back to his work as a cook and has been at work for three months with not the slightest indication of recurrence. At present he says he is gaining in strength daily.

The two refractory cases mentioned were both acute and seemed not to respond at all or very slowly to this form of treatment. One would show considerable improvement for a day or two but invariably would lapse back to the original condition; the second patient recovered completely excepting one knee joint which contained a marked effusion, and seemed not to be affected by repeated injections.

Bruck noticed similar instances, which he explained by the absence of the homologous gonococcus strain from his polyvalent vaccine. It is very evident that this explanation will not suffice, but whether it is due to a special resisting power of the particular gonococcus responsible or to some peculiarity of the infected host, it is impossible to say. Such patients react with fever and leukocytosis, as do all others.

Twelve patients with acute epididymitis were treated, and invariably the pain would subside after the first injection. Usually not more than two injections were necessary, and, indeed, in most instances one, to effect a cure. The swelling begins to subside within twenty-four hours after the first injection. In no instance did the patient remain in the hospital over a week, except in one case in which an overdose was given which will be mentioned later. The patients usually left the hospital on the fifth or sixth day, or just after recovering from the reaction following the second injection.

One patient entered the hospital suffering from acute epididymitis and prostatitis and almost complete retention of urine. About four hours after an injection of meningococci, he passed urine with no apparent obstruction. After three injections he left the hospital apparently cured. No gonococci could be found in the urethra, prostate or vesicles. After he had been at work for five weeks without inconvenience, he went on an alcoholic and sexual dissipation lasting several days, at the end of which period he developed an acute epididymitis on the previous sound side. Even then gonococci could not be found in the urine or urethra.

That these injections are not prophylactic against the development of new complications is evidenced by the fact that one occasionally sees a patient, under treatment, develop an acute epididymitis or an involvement of a new joint. Again a patient may leave apparently completely cured of arthritis to return in a few weeks suffering from epididymitis.

The effect on the urethral discharge is decidedly variable. The discharge in some patients is more profuse for two or three days following the injection, and then rather suddenly subsides entirely; in others a marked decrease in the discharge following each injection occurs, while some of the very chronic discharges seem not to be influenced at all. Regardless of the amount and type of discharge, the gonococci are noticeably decreased in number, and in most instances apparently entirely disappear after from four to six injections.

An attempt was made to follow these patients after their discharge from the hospital. Three months have now elapsed since the first were discharged, and all have been away for at least six weeks. Other than the development of acute epididymitis in three after their discharge there have been no complications or recurrences of any kind. One of the three has been previously mentioned, the second after the cure of a left epididymitis developed epididymitis on the right side one week from the day he left the hospital, while the third developed epididymitis one month after having been discharged as cured of arthritis. All three patients returned to the hospital, without sign of recurrence of the former condition. Over two thirds of all these patients have been heard from directly; some are at work and appear to be gaining in strength daily. Others feel too weak as yet to carry on the heavy work which they have to perform, although they have no pain to prevent them from doing so.

On account of the fact that the reaction following these injections is followed by a chill and general reaction of more or less severity, a very complete physical examination is necessary beforehand. Such a reaction necessarily calls for the increased cardiac activity, so one should proceed with caution when a patient with a coexisting organic heart disease presents himself. The smallest reacting dose of meningococci was given in the following case:

J. W. was suffering from mitral regurgitation of long standing but perfectly compensated, together with acute epididymitis. He passed through the chill with no distress, but in three hours after the injection he became cyanotic, his pulse became irregular and feeble and he had marked precordial pain. This condition lasted from ten to fifteen minutes, and he had no further inconvenience.

No other cardiac irregularities were noted in the entire series. Arnold and Holzel[3] cite Lewinski's case of acute cardiac insufficiency developing after an intravenous injection of gonococci. Heart disease was not known to be present. On the other hand, Luithlen[4] reports a case of gonorrheal endocarditis successfully treated in this manner. There are many instances reported, however, of cardiac symptoms developing in the presence of organic heart disease following these injections, so one should exercise care and judgment in the selection of cases.

From the proper reacting dosage in this series there were noted no other symptoms attributable to the injections. Special attention was given the kidney function, particularly in three patients who had received large doses of colon bacilli. In no instance did albumin appear in the urine, nor did any indication of kidney involvement arise. One patient having a chronic diffuse nephritis with considerable albumin in the urine had two injections with no appreciable change in the kidney function.

Foekler,[5] however, reported epileptiform seizures after similar intravenous injections, and Fischer in one instance noted cerebral symptoms, which passed off in twenty-four hours

[4] Luithlen: Wien. klin. Wchnschr., 1915, 28, 533.

[5] Foekler: Med. Klin., 1914, 10, 47.

Delirium was noted in three patients of this series, all having received a large dose of colon bacilli This condition was of short duration and completely disappeared in twenty-four hours, leaving the patients in a weakened condition, from which they recovered slowly All of these patients had a diarrhea of moderate severity for two or three days One man became so weak that he was kept in bed for ten days, and left the hospital after two weeks As far as could be determined he had completely recovered, and he appeared physically and mentally normal in every respect

COMMENT

It is apparent that any therapeutic effect obtained by the intravenous injection of killed bacteria is not due to any specific reaction in the sense that antibody production is stimulated by specific substances contained in the organisms Jobling and Petersen[6] cite the work of Dunklin, who used proteose injections in typhoid immune rabbits and found a decided increase in the antibody titer, which is explained by a selective stimulation of the hematopoietic system by a nonspecific substance Walther, Hildebrand, Engelhardt, Rolly and Meltzer have reached the conclusion that high temperatures artificially produced have a favorable influence on any established infection, on the other hand, cold seems to retard the formation of immune bodies

The optimum temperature for the growth of the gonococcus in vitro is from 97 to 98 F Any appreciable increase in temperature has a deleterious effect on the life and growth of the organism A sudden rise to 102 F, or over, means certain death of the culture Boerner and Santos,[7] using a diathermic apparatus, found that when subjected to a temperature of 102 2 F for ten hours, the gonococci in the urethra are killed, while an exposure of six hours at 104 F, three hours at 105 8, and one hour, fifty-seven minutes at 107 is necessary to obtain the same results

This principle has been used in various ways in the treatment of local gonorrhea, with considerable success

When acute epididymitis develops and is recovered from, does the fever produced thereby have anything to do with the spontaneous cure of gonorrhea? Many patients with infections terminating thus have had considerable fever during the onset of the complication On the other hand, patients are seen with infections terminating in a similar manner and having had a normal temperature throughout, this, however, does not seem to be a common occurrence

Experimental urethritis in man by the application of a pure culture of gonococcus to the urethral meatus is known to be very constantly produced, but Finger, Ghon, and Schlagenhaufer[8] regularly failed when the experimental patient had a temperature of from 102 2 to 104 F due to some existing disease

A patient recently entered the hospital with acute urethritis of three days' duration A positive gonococcus culture was obtained on entrance The second day in the hospital he had a chill, followed by a temperature of 105 F Malarial parasites were found in the blood, but the chills and fever were allowed to continue for four days, at the end of which time the discharge had stopped, and no gonococci from the urethra or urine were found He remained in the hospital for two weeks, without recurrence of the discharge, having had no local treatment whatever

Equally noticeable is the influence of fever on those infections in the medical wards One rarely if ever sees a gonorrheal infection coexisting with some fever-producing disease like pneumonia, typhoid or malaria, while gonorrheal infections are relatively common among the chronic, nonfever producing conditions

By the intragluteal injection of boiled milk or sodium nucleinate, Muller and Weiss[9] produced temperatures as high as 104 7 F in from six to ten hours Satisfactory results were obtained in epididymitis, prostatitis and arthritis by repeated injections Smith,[10] using normal horse serum, had results corresponding favorably with those produced by antigonococcic serum in gonorrheal complications His therapeutic results ran parallel to the reaction produced, which in turn was proportional to the temperature obtained

On the other hand, Jobling and Petersen[6] assert that intravenous injections cause a fluctuation in the ferment-antiferment balance of the serum as well as changes in the coagulation mechanism and the opsonic complement properties "No single factor can be identified as responsible for all the changes" resulting from this fluctuation, but "a whole train of events is inaugurated, all of which tend toward a condition favorable for recovery from infection" That there are factors at work other than fever seems probable Miller and Lusk[11] have found striking therapeutic results in arthritis due to other infections than gonorrheal, as well as in gonorrheal patients, by the intravenous injection of typhoid vaccine These results, obtained in patients with nongonorrheal infectious arthritis, could not consistently be attributed to fever alone, as the streptococcus and other organisms commonly associated with this condition are known not to be especially heat sensitive Again, why should a patient completely recover from arthritis by this treatment and occasionally still harbor live, cultivable gonococci in the posterior urethra? The temperature and leukocytes presumably being equally distributed why should the organisms in a joint disappear and those in the urethra remain? Numbers and arrangement in clumps may be of some importance, while a less resistant organism may be developed by its growth on a new type of tissue Possibly a continuance of the treatment after recovery from the complication would be sufficient to eradicate the urethral gonococci in all instances[12]

The therapeutic results in the group which forms the basis of this report noticeably correspond to the temperature increase and to hyperleukocytosis Considering the facts that the gonococcus is heat sensitive both in vitro and in vivo, that fever patients cannot be experimentally infected with the gonococcus, and that a fever-producing disease spontaneously cures previously existing gonorrheal infections, there can be but little question that fever artificially produced plays some part in the recovery from these infections

[11] Miller J L and Lusk F B The Treatment of Arthritis by the Intravenous Injection of Foreign Protein The Journal A M A June 3 1916 p 1756

[12] This question is now under investigation as is also the question of finding a substance which may be given safely in standard doses at certain intervals The difference in reaction caused by two supposedly equal bacterial suspensions may be very variable and thus almost necessitates some standard substance if this treatment is to be used by persons other than those familiar with the dangers of a *too severe* reaction

It cannot easily be determined how much influence, if any, the leukocyte increase in the peripheral circulation has, for when artificially produced in the manner employed here, the fever and hyperleukocytosis are invariably present together

It is apparent that the usual treatment of gonorrheal arthritis is not satisfactory in all instances when almost daily one can see an ankylosed joint and atrophied muscles following this condition Should this treatment by intravenous protein injections prove to give permanent results in these conditions, as present data seem to indicate, are we justified in using such measures?

In view of the chronicity of the disease and the destructive complications which commonly arise, it would appear to be a rational procedure when properly used and controlled Until some substance is obtained, however, whose dosage can be more definitely standardized, it seems that this form of treatment should not be used generally by those not thoroughly familiar with the reaction and the manner of regulating the size and interval of dosage of such as used in the work here reported

SUMMARY AND CONCLUSIONS

Intravenous gonococcal vaccines have no specific action either as a diagnostic or a therapeutic agent A similar reaction is secured by suitable injections of meningococci and colon bacilli There is no noticeable difference in the temperature or leukocyte curves produced after the intravenous injection of the foregoing bacterial suspensions

The reactions produced in nongonorrheal patients in every way resembled the reactions in gonorrheal patients, there being no noticeable difference in the temperature and hyperleukocytosis produced

Twenty-four patients with gonorrheal arthritis were treated Complete recovery or marked rapid improvement was observed in all but two instances Eleven patients were treated with gonococci with one failure, and eleven patients with meningococci with one failure, while but two were treated with colon bacilli, and both recovered

Twelve patients with acute gonorrheal epididymitis were treated, and all were apparently completely and permanently cured within a week There was no difference in results produced with the gonococcus, meningococcus and colon bacillus

This mode of treatment in gonorrheal arthritis and epididymitis and at least in some instances of acute prostatitis possesses a decided therapeutic value The results appear to be permanent in character It possesses, however, little or no prophylactic value against the development of new complications

Great care must be exercised in the selection of cases, and patients with organic heart disease should not be treated in this manner No other definite contraindications have been observed

Clinically the benefit to the patient runs parallel with the fever and hyperleukocytosis produced It would seem that these factors play an important role in the treatment

SYPHILITIC BONE AND JOINT LESIONS SIMULATING TUBERCULOSIS *

ARTHUR L FISHER, M D
SAN FRANCISCO

Every paper should present its special points in the beginning so that the attention of those really interested may be fixed This paper aims to give two special points first, that there is a considerable number of syphilitic cases simulating tuberculosis and other bone and joint lesions that escape recognition, second, that there is a considerable number of cases of bone and joint syphilis that do not give a Wassermann reaction

In the past year or two I have seen at least eighteen cases of bone and joint syphilis that have given negative Wassermann reactions Some of these were unmistakable syphilis, as revealed by Roentgen-ray examination In others the nature of the process could not be told in this manner In these two groups of cases the clinical histories are strikingly similar in the individual cases in each group In those frankly syphilitic on Roentgen-ray examination the histories are all the same, pain in the affected part, frequently more marked at night, and little or nothing else They have each been in the hands of one or more physicians, some of whom have suspected syphilis, but on account of the negative Wassermann they have been regarded as something else In this group there were four patients, all of whom promptly improved on the administration of mercury and iodids

In the second group, the larger numerically, the lesions were in and about the joints, rather than in the shafts of the bone as in Group 1, and in these cases, too, there was great similarity in the histories Each of these cases had been treated by one or more doctors, many of these patients had been in institutions, teaching institutions or hospitals, and their trouble had been regarded as tuberculosis and they were treated accordingly by immobilization or operation

As case histories are exceedingly boring, I will cite but a few and make these as short as possible

Case 1—L L, Chinese boy, aged 5 years, came to the Stanford University children's clinic with a sore on the back of his hand He was sent to the surgical clinic, where after a little time, the diagnosis of tuberculosis of the carpal bones was made and confirmed by the Roentgen ray He was kept under observation in the surgical department for about a month, then, as the lesion was regarded as tuberculous, the child was transferred to the orthopedic clinic It was then ascertained that he had had this sore on the back of his hand for about ten months At this time he had the hand in plaster of Paris, and through a window in the plaster it could be seen that there was some swelling and two sinuses The sinuses did not seem to be tuberculous, so the boy was put on mercurial ointment and iodids and improved rapidly in spite of the fact that the Wassermann had been negative shortly before the treatment was begun All plaster was removed, and the boy made a rapid recovery A guinea-pig injected with some of the material from the sinus remained perfectly well

Case 2—F M, white man, aged 42 years, sustained a fracture of the lower end of the radius in December, 1913, which healed without any trouble Oct 7, 1914, the man returned to the surgical clinic, complaining of pain and swelling of the right wrist There was diffuse swelling, pain and limitation of motion Roentgen-ray examination at that time showed probable tuberculosis of the wrist, with a possibility of

---

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit, June 1916

syphilis. He was transferred to the orthopedic clinic six months later after having been treated by immobilization by means of plaster of Paris. As the diagnosis was not clear, the man was allowed to go without any support, to see what would happen. The condition remained the same, certainly no worse. The man had no knowledge of any syphilitic infection and his Wassermann was negative in July, 1915. He was put on mercurial ointment and potassium iodid. His pain and swelling disappeared and motion in the wrist increased. By the middle of August the man was practically well, though with some limitation of motion in the wrist, probably due to his old fracture.

CASE 3.—This case was extremely instructive. A white child, aged 2 years, was brought to the clinic complaining of swelling in the foot and lameness, which had begun about two months before and was gradually growing worse. At that time in the children's clinic syphilis was suspected, but the mother took the child away and did not return for seven months. During these seven months the child had been operated on by two surgeons, independently, and the mother was told by each one that the condition was tuberculosis. When the child was brought back a Wassermann was made, which was negative (there had been no medication). There was a small sinus at this time at the seat of one of the operations. This child was also treated with mercurial ointment. The sinus closed rapidly and the child improved very quickly. This child gained 2 pounds in weight in three weeks after beginning the mercury. In six weeks all the signs and symptoms had disappeared.

CASE 4.—K. H., white, aged 2½ years, was brought to the clinic with swelling of the ankle that had appeared at 2 months of age. This child had been treated at one of the teaching universities over a period of twenty-two months as a case of tuberculosis. The treatment was immobilization by means of plaster of Paris. During this time two sores appeared about the ankle which kept discharging. Wassermann on the mother, father, and child were all negative. There seemed to be a slight fusiform swelling on the fibula, which showed some periosteal thickening on Roentgen-ray examination. The Roentgen-ray report read in part: "suggests syphilis of fibula, possible tuberculosis." On this finding the child was put on mercury and all plaster removed. The sinuses healed quickly and the child improved rapidly. In about two months the symptoms all disappeared and the child was practically well. Treatment was, of course, continued. A fusiform swelling at the upper end of the ulna, discovered accidently in the examination of the child, seemed to remove all doubt as to the nature of the process.

CASE 5.—Mrs. G., aged 32 years, was admitted to the hospital complaining of pain and swelling of the right ankle. Without going into all the details, as this was an extremely obscure case extending over a long period of time, suffice it to say that it was at first considered to be an infectious arthritis, then as tuberculosis of the ankle, and finally as syphilis, on account of improvement under mercury as a therapeutic test, even though the Wassermann was negative. Following an intravenous salvarsan and continuing the mercury this patient has remained entirely well.

These five cases were selected at random, and on account of this method of selection the proportion of ankle cases is unduly high. Practically all the large joints have been represented in this series of cases. Eighteen such cases have been seen, five of the ankle and foot, three of the wrist, three of the hip, one each of the elbow, knee, and back, four of the shafts of long bones, all of which have been under the care of competent physicians, and all of which had been regarded as some condition other than syphilis, most frequently tuberculosis. This would seem to indicate that a large number of such cases are going about, for the experience of no one man or institution is peculiar.

The consideration of these cases brings up several interesting questions. Why do we get so many negative Wassermann reactions in bone syphilis? The percentage I am not able to state, but it seems fairly high, at least 10 per cent. Is it because of the chronicity of the disease, and the lack of amboceptors in the blood, not sufficient being set free to bind the complement? In a manner, it is, perhaps, somewhat comparable to the fact that in a chronic, pyogenic abscess there is no increased leukocytosis. Another point that these cases emphasizes is that fixation of syphilitic joint neither gives relief nor aids in a restitution of the part to normal.

Another point is the large proportion of children in these cases, eight out of eighteen, or really eight out of fourteen, being under ten years of age, quite a contrast to the ordinary teaching that syphilitic joints are not common in childhood.

Another question that comes up is what we are to consider as the most reliable test of syphilis. To my mind it is unquestionably the therapeutic test, and lastly the question of the therapeutic test as a diagnostic method. It is my impression that this should never, or almost never, be omitted in trying to arrive at a conclusion concerning the nature of a chronic process in and about a joint. Exception may be taken to this, but in the present state of our knowledge it seems to be the best test we have for syphilis, and without it one is never sure of his diagnosis.

ABSTRACT OF DISCUSSION

DR. H. W. FRAUENTHAL, New York: Ten years ago, I read a paper on syphilitic bone and joint conditions and I was surprised at the small amount of literature in America on the subject. The orthopedic institutions in the United States had few cases of bone and joint syphilis in their records. I was also convinced of its rarity in another way, in asking some of the leading specialists in New York to discuss the frequency of these conditions most of them said that they had never seen bone or joint syphilis. After collecting a number of cases I concluded that syphilis of the bone and joints was much more common than it appeared to be. The reverse was true on the continent. Most continental observers said it was common in children and adults. Fournier says 42 per cent., and Von Hipple 56 per cent., or more than half. In New York I found it almost impossible to convince others that the Roentgen-ray findings meant syphilis, and that antisyphilitic treatment cleared up the joint conditions. After the Wassermann test came into vogue, and was used uniformly in all our cases, we were surprised at the result. We now find that in almost all blood tests we have 15 per cent. of Wassermann positives. These findings are checked up by other laboratories. Where we failed to get Wassermann positives and the roentgenogram indicated that it was syphilis, by giving salvarsan and neosalvarsan we later often got a positive Wassermann. When the reaction in the child and father was negative, as the father took treatment, and the child did not show a positive Wassermann the mother never was treated. She often showed a positive Wassermann. I have seen persons treated from six months to two years for tuberculous joints in cases regarded as tuberculous who yielded promptly to salvarsan and mercury. Some of these are interesting in their apparent persistence in the appearances of tuberculosis before mercury and salvarsan were tried. One patient, a married woman, had brace treatment for a time. Then as the appearances of the roentgenogram were such that one would think that she would get motion in the joint, she had treatment at another institution for a year and a half with the Zander apparatus and massage, in order to get motion. They failed to obtain any motion in the knee joint. She gave a 4 plus positive Wassermann. A single dose of salvarsan and inunctions over her joint resulted, inside of ten days, in giving her 45 degrees of motion. Another patient, a child with keratitis and Hutchinson's teeth, who had been treated a year and a half at another institution for tuberculous knee joint, under a single injection salvarsan and inunctions of mercury for two weeks got a normal range of motion, although there was an inch and a half difference in the two limbs at the beginning of treatment After four weeks both were alike I think that if it were a custom to take a Wassermann blood test in the case of every child, and then extend it to the mother and father, a number of cases thought to be tuberculous would prove to be syphilitic

Dr John Ridlon, Chicago About thirty years ago, I showed a group of cases before the orthopedic section of the New York Academy of Medicine that I believed to be cases of syphilitic joint disease in children, but not one man there would admit that they were syphilitic, and Dr Shaffer even went so far as to say that the result of antisyphilitic treatment proved nothing because Dr Knight, at the Hospital for the Ruptured and Crippled, had always given mercury and potassium iodid for tuberculous joint disease and had obtained wonderful cures in such cases by this means That was before we had the Roentgen ray, the Wassermann test or tuberculin test to help us in the diagnosis There is no question of the fact that some children have syphilitic joint disease who do not give a positive Wassermann reaction, and it is also true that a certain number of syphilitics do have tuberculous joint disease which can be demonstrated to be tuberculous Therefore, the difficulty is very great in making the diagnosis between a chronic syphilitic joint disease and a tuberculous joint disease The acute cases are quite different from the chronic syphilitic joint diseases, and the patients rapidly get well under treatment, while the patients with chronic cases get well much more slowly, but do get well much more rapidly under immobilization and mercury and potassium iodid than do patients with ordinary tuberculous joint disease The diagnosis has to be made by instinct in many cases, instead of by positive clinical facts

Dr James T Watkins, San Francisco Taken as a whole the paper is important, first, because it points out the danger even painstaking observers run of mistaking a syphilitic bone lesion for a tuberculous condition if they put their trust implicitly in the absence of a positive Wassermann reaction Those of us who see much bone and joint disease must agree with Dr Fisher that bone and joint syphilis is much more prevalent in childhood than the literature would seem to indicate Second, of those cases which are clinically syphilitic, Dr Fisher finds that 10 per cent do not give a positive Wassermann reaction I am of the opinion that to estimate them at 20 per cent would be to get nearer the mark Third, of these Wassermann negative syphilitics, those with involvements of the shafts of the bones only present pain worse at night as the one constant symptom These have, however, definite Roentgen-ray changes Fourth, in the group which presents joint involvements, the Roentgen-ray changes may be misleading, suggesting tuberculosis Therefore, all you have to go on is limitation of motion and pain, pain which is not relieved by mechanical protection of the involved joint The only reliable test is the therapeutic one If one would reduce the teachings of this paper to a sentence, one would have to go back to the dictum of the pre-Wassermann clinicians and say with them 'When in doubt treat for syphilis"

Dr Edward Hatch, New Orleans During the last few years I have seen several cases in adults, some of whom came for frank, and some for indefinite joint pain The diagnosis was made by the Roentgen ray, and in each case, the Wassermann test was negative In practically all, the luetin test was positive Therefore, I should like to ask Dr Fisher whether he has made tests of the luetin reaction, and whether he considers this an aid in the diagnosis

Dr Edwin W Ryerson, Chicago It is important, in this connection, to remember that some cases with a negative blood Wassermann may give a positive spinal fluid Wassermann This is not recognized quite enough, nor is quite enough advantage taken of it I have seen about ten cases in the last few years in which the blood Wassermann was negative, and the spinal fluid Wassermann was absolutely positive

Dr Walter G Stern, Cleveland Let us clinicians not forget that Wassermann stated in his original paper that a negative blood reaction is of no diagnostic or prognostic value, unless the reaction continues negative for as long a period as a year to a year and a half, so that one must not be too hasty in ruling out syphilis on the basis of one or two negative serologic examinations

Dr Reginald H Sayre, New York I think that the old Scotch verdict, "Not proved," is very applicable to this case, and I only wish to question the writer of the paper in regard to one point I agree with everything else This point is that he feels that these patients are not benefited by protection Now, I believe that in a great many cases it is as wise to give protection to the syphilitic as to the tuberculous joint I have seen syphilitic hips that went for a considerable period of time with protection and hip splints not undergoing any shortening, and that, when the weight bearing was again permitted, began to telescope It seems logical, in a soft bone, to relieve it from strain, if you wish to preserve continuity

Dr C B Francisco, Kansas City, Mo In the years 1907-1908, at the Hospital for Ruptured and Crippled, before the time of the Wassermann test, in admitting the children we did not label a single case syphilis of the joint diagnosing these cases as tuberculosis, but I hesitate now to make that diagnosis I should like to go a point further in these cases, more especially in those involving the bone near the joint, which are very difficult at times to diagnose Strange to say, some of these patients will get well without antisyphilitic treatment, and you think that you have a tuberculous joint, only to have the patient come back, in the course of a few years, with a chronic syphilitic joint somewhere else, proving that the condition was probably syphilis from the start Nichols says that 50 per cent of the cases of latent bone syphilis give a negative Wassermann, and that we should rather rely on the Roentgen ray than on any one other factor for diagnosis There is one difficulty with the therapeutic test it will not relieve the endosteal bone changes Mercury and iodid will relieve the periosteal changes and the gummatous changes, but the endosteal thickening will remain Another point, advocated particularly in England, is that salvarsan is of no particular value in bone syphilis Mercury and potassium iodid, in the periosteal and gummatous type, should be the treatment of choice

Dr Leonard W Ely, San Francisco Opinion in regard to bone and joint syphilis has changed There used to be skepticism concerning the occurrence of joint syphilis in childhood The essayist has brought out the lack of reliability of the Wassermann test There is no reliable test for joint syphilis The Wassermann test, the Roentgen ray, the clinical course, the history, must all be considered, and then we are not certain about a diagnosis The gross bone changes in syphilis of the joints are exactly the same as those of tuberculosis The changes in the synovial membrane are, in gross, also the same The microscopic and histologic changes are not absolutely reliable If we find what we consider a tubercle, we say the joint is tuberculous, but the pathologist tells us that we cannot depend on the presence of giant cells, and what we are wont to regard as the characteristic changes of tuberculosis The guinea-pig test is the most satisfactory, and yet, we have just had a case in our clinic that we have been working over for the past six months, the diagnosis lying between so-called Legg's (Perthes') disease, syphilis and tuberculosis The patient went to another clinic and was operated on for giant-cell sarcoma The tumor was sent to a pathologist who said that it was probably tuberculosis The material when injected into a guinea-pig gave a negative tuberculous reaction, and we thought that the case was closed Later, however, the operator told us that he had administered tuberculin and got a reaction, and that he regards the case now as tuberculosis Personally, in the absence of the animal test, I regard the therapeutic test as the most reliable

Dr Emil S Geist, Minneapolis I have had several cases in my practice in the last few years in which the diagnosis of bone or joint syphilis was made The history was positive, the Wassermann reaction was also positive, and the roentgenogram showed definite joint lesions, yet when the therapeutic test was applied, it did not give any results When the physician who had correctly diagnosed the case came in we told him that we thought we were dealing with tuberculosis or some other bone or joint trouble Nevertheless, the cases turned out to be syphilitic It has been my experience that in some of these cases, we must push the treatment to the limit, and that really the therapeutic test had not been tried when it had been found wanting in the minds of these men The point that I would make is that bone and joint syphilis is more resistant to treatment than other forms and I have been accustomed to transfer these cases to the syphilologist, because he has been handling more syphilitic remedies and knows better how to apply them than I

Dr Henry Ling Taylor, New York Not infrequently, when the Wassermann is negative in the child, it may be positive in one or both parents, this has been found true in several cases lately It pleased me very much to hear one of the speakers say that the old fashioned mixed treatment is more reliable than salvarsan in bone and joint cases I have also found this to be the case, and it does not seem to be generally known Some men think that they are giving antisyphilitic treatment when they give potassium iodid, but this is a delusion, mercury is the active agent

Dr Robert W Lovett, Boston Most of the remarks have been coincident with my own experience One point I should like to mention is the stimulation of chronic osteomyelitis by syphilis I have had patients with chronic osteomyelitis who gave a positive Wassermann reaction and improved under antisyphilitic treatment About a year ago I went through some plates with Dr Post, professor of syphilis at Harvard University, who has given great attention to the appearances in bone and joint syphilis Some of the plates showed bone syphilis very clearly Some cases that we had diagnosed as osteomyelitis he thought were characteristic of syphilis Many of them were old plates

Dr A E Horwitz, St Louis We see a surprising number of these cases in St. Louis, probably because we look for them In most of these cases the Wassermann is negative, the percentage of negative results being fully 50 per cent , so we do not, as a rule, rely on this test, but look for other essential points In the congenital form, there is usually multiple joint involvement, so we have come to rely on this It is essentially polyarticular, not like tuberculosis with one or two joints involved but, in most cases, quite a number of joints One strong point is the shaft involvement In the joint where the involvement occurs, by looking carefully, we can find some slight involvement in the opposite end of the shaft If we do not, we find a symmetrical involvement of the opposite limb in the same joint That has been very striking and very often demonstrated In spite of a negative Wassermann reaction, we can, therefore, make the diagnosis, because of the fact that the disease improves under antisyphilitic treatment Another point is that in the congenital cases, which are essentially polyarticular, the condition is not entirely articular, but extends into the shaft somewhat, and even in the acquired form of syphilis, wherever there is bone involvement, it also extends into the shaft, and possibly *from the shaft* to the joint So much is this so that we tried to claim that acquired syphilis is not an actual joint condition, but an extension from the shaft, while the congenital form is joint involvement proper, extending to the shaft

Dr Arthur L Fisher, San Francisco My object in bringing up the subject was to set forth the fact that the Wassermann test is unreliable in two ways first, that in a large proportion of syphilitic cases one gets a negative Wassermann, and second, and more important, because of the interpretation given by the profession at large to the Wassermann, that a negative Wassermann means no syphilis We know that this is not true, and I have tried to bring out the fact that all these patients have been in the hands of competent physicians who, on account of the negative Wassermann, regarded the cases as not syphilitic In answer to the remark about the spinal fluid Wassermann, I would say that it is unquestionably a fact that it happens with great frequency that a blood Wassermann is negative, and a spinal fluid Wassermann positive These cases, however, are usually central nervous system syphilis—tabes or cerebrospinal syphilis, and you get in them the so called Charcot joints I have not seen any joint involvement, except these, in such cases With regard to the protection of the joint, I would say that it does not give relief of symptoms in these cases, and does not tend to a restoration to normal Of course, if a diseased area is bearing weight it is wise to protect it I am glad that the subject of the histology of the condition was brought up, because there is a broad general statement that can be made in regard to it, and that is, that without finding the tubercle bacillus, you cannot be sure whether you are dealing with syphilis or tuberculosis You can usually, if you look at a slide, say, "This is a tubercle" or "This is a gumma", but you can never be sure, and even an expert pathologist will not usually give a definite diagnosis on this point Dr Lovett brought out an interesting point, the difference between syphilis and chronic pyogenic osteomyelitis We have been coming to believe that when pyogenic osteomyelitis is multiple, it is usually in a syphilitic patient, either congenital or acquired, and you will usually find some evidences of syphilis in the family in these cases

REPORT OF A CASE OF STRANGULATED DIAPHRAGMATIC HERNIA, WITH OPERATION AND RECOVERY

Charles E Hawkes, M D, Providence, R I

In an article on stab wounds of the diaphragm, with diaphragmatic hernia or evisceration, Dr Charles C Green[1] has reported a total of 123 cases collected from the literature, together with six cases of his own

To this list I wish to add a case of my own, in which the patient was operated on at the Rhode Island Hospital, this summer, during my term of service This case was especially interesting from the fact that the hernia became suddenly strangulated, and the patient's convalescence was complicated by a prompt attack of delirium tremens

The patient, A Le C, man, aged 49, single, white, laborer, well developed and well nourished was brought to the Rhode Island Hospital in one of its ambulances, Nov 17, 1915 He had been stabbed by his roommate, during an argument as to who should do the cooking The wound was in the left eighth intercostal space, nipple line, about 3 cm in length and 1 cm in depth, which bled readily No fracture of the ribs could be detected, nor perforation of any cavity, nor evidence of internal injury The patient complained of extreme tenderness about the cut The incised wound was treated in the accident room with iodin, and sutured with three silk sutures Three days later, the wound was clean, the patient's condition was satisfactory, and he was discharged from the house, and referred to the outpatient department for any further necessary dressing and attention

July 21, 1916, the patient was readmitted to the hospital in the ambulance His history was as follows Since his previous discharge from the house, he had felt well except for occasional belching of gas, to which he paid no attention He complained of no other gastric symptoms He had been a heavy drinker

Two hours before his second admission to the hospital, while at work, he was seized with a sudden, severe attack of pain, in the epigastrium He vomited once, soon after the onset of the attack The pain continued with great severity He managed to get to a drug store, where he collapsed

The man was in extreme agony His face was markedly cyanotic, the pulse almost imperceptible, the skin cold and clammy A general examination was not made, because of his extremely poor condition

The abdomen was exceedingly tender in the epigastrium, and the rectus muscles were rigid to a level with the umbilicus, below which point they were much less tense It was tympanitic all over Distention was limited to the epigastrium The liver dulness was not obliterated Below the umbilicus the abdomen appeared somewhat sunken, fairly soft on palpation and not tender On the left side, the tympany extended to the fourth intercostal space Owing to the patient's critical condition and to the imperative need for rapid therapeutic action, all further examinations, including that of the chest, were postponed

---

[1] Green, C C Stab Wounds of the Chest Involving the Diaphragm, with Diaphragmatic Hernia or Evisceration, The Journal A M A, July 15, 1916, p 178

He was given a quarter of a grain of morphin subcutaneously, and 600 c c of saline solution intravenously Heaters were applied externally He responded quickly to this stimulation, the cyanosis diminished, and the pulse became stronger and regular One hour after his admission to the hospital, he was sent to the operating room As the patient had been free from all symptoms referable to his previous stab wound for eight months, and since his present attack came on suddenly and with severity in the epigastric region, and followed an alcoholic history, a diagnosis of perforated duodenal ulcer was made The white blood count was 17,000

Under ether anesthesia, a high right rectus incision was made through the abdominal wall No gas or fluid was encountered when the peritoneal cavity was opened The duodenum except for a few veil-like, red adhesions, was normal, as was also the gallbladder The right lobe of the liver was somewhat enlarged The appendix was short, small and atrophied The ileum was collapsed The right kidney was normal The omentum was not discernible On examination of the stomach no adhesions or thickening of its walls could be detected When an attempt was made to pull it down into the wound for a more thorough inspection, for some reason it seemed to be firmly anchored behind and could not be drawn down Further examination behind the stomach disclosed intestines passing through a vertical rent in the left leaf of the diaphragm To facilitate the operation, an incision was made transversely across the left part of the abdomen, to the extent of 5 to 6 inches from the upper end of the original incision, and the triangular flap laid back, making a large square opening to work through The intestines were found so firmly wedged in the wound of the diaphragm that this also had to be enlarged 1 or 1¼ inches, making the entire opening about 2 or 2½ inches Fairly firm adhesions between the intestines and the hole in the diaphragm had to be broken up before the hernia could be reduced The transverse and part of the descending colon, the omentum, and about half of the small intestines were finally withdrawn from the left chest, through this rent in the diaphragm The omentum was black from extravasation of blood, and was bleeding from many small points It was somewhat adherent about the opening in the diaphragm, and had to be forcibly freed and tied in places The mesentery of the intestines also contained large areas of extravasated blood and abrasions The jejunum was distended, and dark in color The condition of the omentum, mesentery and jejunum was undoubtedly due to the sudden strangulation of the parts, through the traumatic opening in the diaphragm

An interesting point was the ease with which the apex of the heart could be palpated and the pulsations counted through the diaphragmatic rent

The edges of the diaphragmatic wound were seized with Kocher's clamps, and approximated with through-and-through sutures of No 2 chromic catgut, doubled To facilitate haste, a number of through-and-through silkworm-gut sutures were taken in the triangular abdominal wound, supplemented by chromic catgut sutures through the fascia, muscle and peritoneum, and silk in the skin No drain was used

The nurse in the laparotomy room reported that the patient came from the operating room at 7 p m in poor condition He was given a shock enema, which was retained Camphor in oil, 30 drops, was given subcutaneously at 7 30, and every two hours thereafter Caffein sodium benzoate, 2 grains, was given subcutaneously at 8 30 and every two hours Morphin ¼ grain, was given at 8 45 subcutaneously, and repeated in four hours One pint of Murphy drip saline was given by rectum at 11 30 and retained The patient voided at 1 a m He had a good deal of pain all night The following day, the stimulation was continued, and in addition two high enemas of Epsom salt, glycerin and water were given with good gas results The patient talked irrationally at times during the night

The next day, July 23, he became restless and delirious, got out of bed and walked around the room, insisting that he was all right and desired to go home He was transferred to the quiet ward, where his delirium tremens required large doses of sedatives, and some whisky to control. Here he remained under close observation for seven or eight days before it was considered safe to return him to the laparotomy room Part of the time he had to be restrained to be kept in bed

August 1, the stitches were removed and two small plain rubber tissue drains were inserted down to the muscle, to drain small collections of seropus from the incision wounds He slept well from now on

August 14, the rubber tissue drains were left out. The patient was given a back rest, in bed

August 16, the patient was out of bed, in a chair

August 19, he was discharged from the hospital practically cured He returned several times, at intervals of three or four days for dressings The two sinuses, where the drains had been inserted, eventually closed

The temperature chart showed the following Temperature rose to 103 the third night after operation, pulse 115 and respiration 34, during his mental excitability Normal was soon reached, and the temperature touched 100 on only three or four occasions afterward, falling to normal or 99 the next day

The urine, July 22, showed a rusty color, and strong acidity, specific gravity 1 020 albumin a trace, and sugar absent In the sediment were numerous granular casts a few squamous epithelial cells, and an occasional white blood cell

Therapeutics

DISTURBANCES OF THE KIDNEYS

(Continued from page 287)

CALCULI IN CHILDREN

That urinary calculi occur in children is, of course, recognized, but a summary of the subject by Collins[62] shows that one investigator found "that 45 per cent of 5,900 cases of calculus occurred in children, and that children under five years are especially prone to the condition " Collins finds that children resemble adults in that renal calculi occur in boys twice as frequently as in girls, the majority of cases being found in children under 2 years of age Holt says that small renal calculi are very common in infants, and though these calculi may be voided without symptoms, other observers are of the opinion that renal colic in infants is not rare

The causes of these deposits in children are probably too much nitrogenous food, too much calcium in the food, perhaps too much phosphate in the food or medication, and often an insufficient amount of water Perhaps frequently there are the added factors of bacterial infection and delayed passage of urine to the bladder Gout in the parents can scarcely be called a predisposing cause Bacterial infection, general and later focal, is doubtless a frequent cause With bladder calculi, renal calculi may be presupposed When blood or pus is found in the urine, a careful examination should be made

Sudden pain, apparently abdominal (in a child too young to describe its symptoms), vomiting, and suppression of urine, or bloody urine, suggest a kidney stone, sudden high fever added to these symptoms indicates a kidney infection A history of gravel, or of passage of urine showing a quantity of sediment, may aid in the diagnosis Roentgenograms should be made before operative interference is undertaken

---

[62] Collins A N Urinary Lithiasis in Infancy Am Jour Dis Child October, 1913, p 245

It is very difficult to decide whether in young children morphin or codein would mask a necessary symptom in making a diagnosis — as in appendicitis or intestinal obstruction, for instance. At the same time, we are not justified in allowing a child to suffer agony when an adult would insist on the alleviation of his pain. Therefore when the renal colic has been diagnosed, the pain must be diminished. Hot baths may cause relaxation, with a dose of codein proportionate to the age of the child, a few whiffs of chloroform may also be needed. Long continued use of chloroform, however, is not justifiable.

A calculus which has not been passed should be sought by the Roentgen ray and surgically removed, as the lodging of such an obstruction in any part of the urinary tract is a greater menace to a child than to an adult.

The prognosis is unfavorable as many cases necessarily remain undiagnosed until necropsy. Surgical treatment of diagnosed cases, however, should give more satisfactory results.

The child who has passed a stone should be given the following prophylactic treatment: a properly balanced diet, regulation of the bowels, and plenty of water.

BILATERAL KIDNEY STONES

In children, as well as in adults, we frequently find that if stones are located in one kidney, the same condition will be discovered in the other. Speaking conservatively, this is true of 20 per cent of the cases. This is necessarily true as any urinary or digestive disturbance has a tendency to affect both kidneys unless one kidney is made more susceptible by some localized predisposing cause. Hence, before operation both kidneys must be examined by the Roentgen ray. When stones are found in both kidneys, operation on either kidney is accompanied by greater hazard. Of course the more weakened either or both kidneys are from pus, hydronephrosis or nephritis, the graver is the prognosis. Whether or not the two kidneys in these bilateral cases should be operated on at once is a nice medical and surgical question, careful consultation, tests of function and of the blood for retention nitrogen must make the decision.

HEMATURIA

Hematuria, or blood in the urine in tangible amounts, should always be investigated, as it may be of serious import. Traces of blood, which are frequently found, may lead to the discovery of various disease conditions. Real hematuria may appear as clear blood or blood mixed with urine or the urine may appear smoky, as occurs when the kidney substance is the source of bleeding, the blood being thoroughly mixed with urine, albumin and debris. Small amounts of blood may also be found in the urine in chronic nephritis of all types. Other conditions that cause or allow hemorrhage into the urinary canals are traumatism, calculi, cystic degeneration of the kidneys, carcinoma or tuberculosis of any part of the urinary tract, some blood diseases, especially hemophilia, acute infections of the malignant type, acute nephritis, septic infarcts of the kidney substance, and more rarely echinococcus infection. Blood may of course also appear in the urine owing to bleeding from the ureters, bladder, prostate or urethra. Rarely exposure to severe cold may cause blood to appear in the urine in certain individuals. Cardiac insufficiency, with passive congestion of the kidneys, congestion of one kidney due to displacement or to pressure on its blood vessel, a serious lordosis, or serious disturbances of the liver may cause kidney hemorrhage. Cases of hemorrhage have been reported in which there was localized dilatation of the blood vessels. This condition, which is rare, has been termed renal angioma or renal varix. Hematuria as well as hemoglobinuria may sometimes be caused by certain forms of pernicious malarial fever.

Elsner[63] found hemorrhage of the kidneys in 100 per cent of acute tubal nephritis, in 100 per cent of secondary congested kidney (passive hyperemia), in 33 per cent of chronic tubal nephritis, and in 14 per cent of chronic interstitial nephritis. These surprisingly high percentages give evidence of the frequency of hematuria, and should warn against operative interference except as a last resort. A floating kidney which is bleeding should be anchored, since a kidney so displaced as to cause interference with the outflow of blood from the renal vein must be passively congested.

It has been suggested that a kidney passively congested for some time becomes enlarged through dilatation of its blood vessels and is subjected to pressure from its capsule. Decapsulation would relieve this passive congestion and the resulting hemorrhage.

Blood issuing from the urethra will generally precede the passage of the urine or appear in the first jet. If it comes from the posterior urethra or from the prostate gland region, it is apt to follow urination. Blood coming from the bladder may be well mixed with urine, it may appear with strings of mucus, or it may follow urination. Blood from the ureter or from the pelvis of a kidney may follow urination, or the urine may be more or less mixed with it. As stated, blood thus occurring with nephritis generally causes a smoky urine, although clear blood may come from some lesion of the kidney substance.

Urethroscopic and cystoscopic examinations may disclose the origin of the blood. If its source is found to be in the kidneys, the passage of ureteral catheters will show the kidney from which it comes. Roentgenograms may reveal a calculus in the pelvis of a kidney or in the ureter as the cause of the hemorrhage. If the bleeding is due to a stone, absolute rest will usually cause a cessation. If it is due to tuberculosis — a common cause — or to some kidney growth, rest will probably not be efficacious, but, if the hemorrhage is localized in one kidney, surgical intervention may be required. Before resorting to this measure, however, one should take into consideration the health of the other kidney, the seriousness of the bleeding, and the gravity of the symptoms. If the bleeding is due to a displaced kidney, rest and abdominal support will usually remedy it. If it is due to circulatory insufficiency, cardiac tonics and rest will generally cure the condition, as whatever improves the system will of course diminish the hematuria.

Gallic acid has at times seemed to check renal hemorrhages due to disturbances of the blood or to a growth in the kidney. The use of gelatin and calcium chlorid has sometimes been beneficial, as has also been dry cupping over the offending kidney. Cotarnin hydrochlorid (stypticin) and cotarnin phthalate (styptol) have been used with apparent success in some cases of bleeding from the kidney substance. Injections of epinephrin solutions into the pelvis of the kidney through the ureteral catheter has suppressed bleeding for varying periods Blood serum, the administration of suprarenal gland, or the administration of thyroid gland sometimes will prove effective when the hemorrhage is due to a hemophilic condition

---

[63] Elsner New York State Jour Med 1913 13, 144

It should be emphasized that the most frequent causes of kidney hemorrhage are renal stone, tuberculosis and circulatory insufficiency It is associated with acute nephritis When accompanied by chills and fever, even though other evident sepsis is lacking, a septic infarct is probable It should also be remembered that hexamethylenamin, which is now so frequently given, may cause hematuria Occasionally blood vessel pressure from an abdominal tumor, or in pregnancy, may produce kidney hemorrhage

ESSENTIAL HEMATURIA

Before applying this designation to a kidney hemorrhage, one must be certain that this particular condition may not come under some other heading Many unexplained hematurias are thus termed, and Braasch[64] states that essential or unexplained hematuria is not a rarity He found that 75 per cent of seventy-seven cases were in males, the majority of whom were between 40 and 50 years of age The duration of this intermittent hematuric condition varied, sometimes continuing for many years Braasch found that high blood pressure was not a usual factor These attacks, in some instances, were accompanied by pain If the bleeding is preceded by a chill, if there is any pus or much albumin, a localized kidney inflammation is the probable cause of the hemorrhage The presence of bacteria signifies perhaps a focal infection Braasch found that in some cases injections of epinephrin solution, 1 2,000, into the pelvis of the kidney, while not curative, would stop the hematuria for a long time He advises nephrectomy in persistently recurrent essential hematuria, when one kidney is healthy, having found nephrotomy of no value in this type of bleeding It should be emphasized that before nephrectomy is employed in these cases, all less severe measures must be thoroughly tried If bleeding then does not cease, the patient becoming exhausted and anemic, removal of the kidney is justifiable Syphilis in some instances causes hematuria, and proper treatment of this disease may be the remedy required

The pathology of these bleeding kidneys generally discloses the fact that the blood flows from the glomeruli, and that there is some kidney degeneration — a fibrosis not unlike that due to prolonged passive congestion or to heart insufficiency, as pointed out by Spitzer[65]

It should be noted that, in many cases called "essential hematuria," plausible causes for the bleeding have later been discovered It should also be noted that chronic nephritis may be present for a long time, causing hemorrhage even though the urine shows, on repeated examinations, no albumin and no casts Such a condition may occur when there is arterial degeneration

HEMOGLOBINURIA

In this condition the coloring matter of the blood appears in the urine without the corpuscles, the urine being dark and containing blood pigment and broken down red corpuscles It may occur in diseases of the blood such as pernicious anemia and purpura, in conditions causing the destruction of the red corpuscles, such as pernicious or malignant infections, in pernicious malaria, or in hemoglobinuric fever, and it may occur when nontested blood is transfused into an anemic patient or into a patient who has suffered hemorrhage The latter incident rarely occurs at the present time, as it is now recognized that the donor's blood must be tested before transfusion can with safety be performed Besides the causes just enumerated, a hemoglobinuria may be produced by poisons of the phenol type, such as coal tar products and potassium chlorate, and also by some snake poisons Carbon monoxid (illuminating gas) poisoning is a frequent cause Chloroform anesthesia may occasionally bring about this condition, as may also large doses of quinin It is not necessary to discuss, in this connection, whether it is more hazardous to allow a pernicious malarial fever with kidney hemorrhage to run its course, or to decrease the fever by administering large doses of quinin, which will tend to increase the flow of blood

Some time ago it was shown by Pearce, Austin and Eisenbrey[66] that there must be a concentration of hemoglobin in the blood of 0 06 gm per kilogram of body weight before hemoglobin appears in the urine If there are very large amounts of hemoglobin in the blood stream, bile pigments will also appear in the urine A limited amount of the hemoglobin debris is cared for by the liver, but when this amount is exceeded the excess debris is secreted by the kidneys Hemoglobinuria is frequently accompanied by hematogenous jaundice

Paroxysmal hemoglobinuria is rare, but periodic attacks, with oxyhemoglobin and methhemoglobin in large amounts in the urine, may occur Men seem to be more frequently afflicted with this form of hemoglobinuria than women These attacks may be induced by cold, and in some cases by syphilis They may be preceded by a chill and followed by a fever, with oft recurring myalgic pains The urine will probably not continue hemoglobinuric longer than twenty-four hours Malarial fever may be eliminated as producing such an attack, however, there usually is some hidden but definite cause

PYURIA

Pus may appear in the urine in amounts varying from very small to large A vaginal cause of pus in the urine in females can readily be excluded by catheterizing In urethritis and cystitis the pelvis of the kidney is more frequently involved in the female than in the male, gonorrhea rarely ascending to the kidney in the male[67]

The bacteria most frequently found in urine are the streptococci, staphylococci, gonococci, colon bacilli, pneumococci and tubercle bacilli

C Beeler and H F Helmholz[68] find, after examining 118 specimens of the catheterized urine of sixty-one female children, that colon bacilli are not normal inhabitants of the female urethra but in extra-urinary infections occurring during the first two years of life the colon bacillus is frequently found in the female urethra, in girls over two years of age the urine is usually free from colon bacilli

THE TREATMENT OF BURNS BY PARAFFIN

THE JOURNAL has previously commented on the secret proprietary preparation "Ambrine," exploited in this country some years ago as "Hyperthermine" and "Thermozine," and more recently given prominence in this country by extensive newspaper comment In the *British Medical Journal*, Jan 13, 1917, Lieut -Col A J Hull of the Royal Army Medical Corps, who has investigated the treatment, reports that he believes that under this treatment slight burns heal with singular rapidity, and persons severely burned recover who would not have recovered so completely under ordinary methods of treatment He believes that the results obtained depend almost wholly on mechanical factors the protection of the burn from the air, the protection of the newly formed granulations from damage, the splintlike effect of the wax in holding the damaged tissue immobile and at rest, and the heat of the applications, which may encourage the lymph flow and the blood supply to the new capillaries The paraffin cast likewise provides a suitable nidus in which epithelium will proliferate Dr Hull, believing in the efficacy of the treatment, experimented to find a preparation which would be equally efficacious Laboratory experiments were made with a view to impregnating paraffin with various substances and to produce a paraffin possessing the requisite melting point, plasticity and adhesiveness He found that paraffin of a suitable melting point, if heated to 130 C by superheated steam, became mobile and workable and was lowered 2 degrees in melting point It is this superheated steam which is the essential process in the manufacture The results of the application of hard paraffin — treated with superheated steam — to burns seemed indistinguishable from those of "Ambrine"

Dr Hull claims that better results are obtained by the addition of certain antiseptic and stimulating substances The wounds become clean more rapidly, pain is decreased, and the offensive smell associated with the "Ambrine" dressings is avoided It was found necessary to change the treatment of sluggishly healing burns treated by "Ambrine" to a paraffin containing an antiseptic The change was always beneficial

Dr Hull finally succeeded in preparing a formula which in numerous cases gave excellent results Severe burns healed without cicatrices and without extensive scarring The treatment was practically painless He found that burns became clean more rapidly under this formula than under the "Ambrine treatment' The mixture, which he calls No 7 paraffin, and the method of treatment are thus described

> The paraffin treatment is begun at the first dressing very exceptionally in very septic burns, the paraffin is replaced by hot boric fomentations for two days after two days of paraffin treatment
>
> The burn is washed with sterile water and dried The drying is accomplished by placing a dry piece of gauze over the burn An electric drying apparatus such as is used by a hairdresser for drying hair if available is a convenient method of drying the burn
>
> The burn is next covered with a layer of paraffin at a temperature of 50 C The No 7 paraffin has a melting point of 48 C The temperature may be estimated by waiting until the wax shows a solidifying film upon the surface A broad camel hair brush sterilized in wax has been found to be a rapid and painless method of applying the paraffin A spray may be used, but sprays readily get out of order, are troublesome to use and the dressing takes longer In theory a spray should be used in order to prevent any danger to the epithelium In practice, we have found a brush skilfully used, sufficiently satisfactory Sprays are indicated in very painful cases A metal spray of rather large bore should be employed The spray must be immersed in hot water during use
>
> A thin layer of cotton wool, cut the same size as the area of the burn is placed over the wound after the first layer of paraffin has been applied This layer of wool is covered with a second layer of paraffin The wool is cut in thin sheets and pressed between layers of paper in order to obtain thin layers of wool The dressing is completed by applying wool and bandage The burns are usually dressed daily In the later stages, when the burn is clean and only a small amount of pus is formed, the dressing is changed every forty-eight hours
>
> Blisters are not interfered with in any way at the first dressing, the paraffin is applied after washing the burn At the second dressing the dead layers of skin are cut away Sloughs usually separate after a few dressings The separation of sloughs is accelerated by applying a layer of jaconet over the wool and paraffin beneath the wool and bandage dressing

FORMULA FOR NO 7 PARAFFIN

Resorcin	1 per cent
Eucalyptus oil	2 per cent
Olive oil	5 per cent
Paraffin molle [soft]	25 per cent
Paraffin durum [hard]	67 per cent

> Melt the paraffin durum and add paraffin molle and olive oil Dissolve the resorcin in absolute alcohol (soluble 2 in 1) add the alcoholic resorcin and lastly add the eucalyptus oil when the wax has cooled to about 55 C
>
> A smaller amount of resorcin may be used The whole of the resorcin does not remain in suspension, and we have used a paraffin containing 0 25 per cent resorcin with good results
>
> Difficulty having been experienced in obtaining resorcin in large quantity, beta-naphthol, which has the additional advantage of being a cheaper antiseptic has been substituted for resorcin in more recent preparations as follows

Beta naphthol	0 25 per cent
Eucalyptus	2 0 per cent
Olive oil	5 0 per cent
Paraffin molle [soft]	25 0 per cent
Paraffin durum [hard]	67 75 per cent

> We have employed No 7 paraffin in certain stages of the treatment of trench feet The mode of application of paraffin to the ulceration following frostbite is in every respect similar to the application of paraffin in the treatment of burns, and the results have been equally satisfactory

---

Experimentation on Man —The limits of justifiable experimentation on our fellow creatures are well and clearly defined The final test of every new procedure, medical or surgical, must be made on man, but never before it has been tried on animals There are those who look on this as unlawful, but in no other way is progress possible, nor could we have had many of our most useful but very powerful drugs if animal experimentation had been forbidden For man absolute safety and full consent are the conditions which make such tests allowable We have no right to use patients entrusted to our care for the purpose of experimentation unless direct benefit to the individual is likely to follow Once this limit is transgressed, the sacred cord which binds physician and patient snaps instantly Risk to the individual may be taken with his consent and full knowledge of the circumstances, as has been done in scores of cases, and we cannot honor too highly the bravery of such men as the soldiers who voluntarily submitted to the experiments on yellow fever in Cuba under the direction of Reed and Carroll The history of our profession is starred with the heroism of its members who have sacrificed health and sometimes life itself in endeavors to benefit their fellow creatures Enthusiasm for science has, in a few instances led to regrettable transgressions of the rule I have mentioned, but these are mere specks which in no wise blur the brightness of the picture—one of the brightest in the history of human effort—which portrays the incalculable benefits to man from the introduction of experimentation into the art of medicine —Osler *Transactions of the Congress of American Physicians and Surgeons* 1917, 7, 7

IPECAC AND DYSENTERY

Ipecac is the root of a Brazilian herb. It is said to have been in common use in its native country long before it was brought to Europe by Piso at about 1650. Shortly afterward a charlatan by the name of Adriaan Helvetius placarded Paris with the announcement that he had a cure for dysentery. Hearing of this, Louis XIV summoned him to treat the dauphin, who was suffering from this disease. The patient recovered, and the formula, which Helvetius is said to have obtained from a physician in the Netherlands, was purchased by the government for 1,000 louis and made public. Ipecac was one of the ingredients of the formula, and from that day to our time ipecac has been used as a remedy in dysentery, but with varying fortune, it being vaunted by some as a specific and condemned by others as useless. Under any circumstances the vomiting was a heavy drawback.

Until not so very long ago dysentery included all diseases in which blood and mucus appeared in the stools; now we know at least two etiologic varieties, and there is no doubt that the success or failure of the ipecac treatment of the old days in large measure depended on what kind of dysentery was being treated. In India the use of ipecac in dysentery began early and was kept up, as we learn that in 1881 massive doses were used not only in uncomplicated cases but also in cases with abscess of the liver.[1]

In 1817 Pelletier isolated from ipecac the so-called active principle, the alkaloid emetin, which also was used in dysentery with success, at least by some, and in 1910 Vedder in Manila demonstrated that emetin, even in highly dilute solutions, kills *Amoeba histolytica*, the cause of amebic dysentery. Shortly afterward Rogers[2] in India was able to cure acute amebic dysentery in a few days by means of a few hypodermic doses of emetin hydrochlorid. This striking therapeutic triumph has been repeated innumerable times, and is being repeated daily in all parts and corners of the world where amebic dysentery prevails, and emetin is today accepted as an almost ideal specific, being harmless to the body in doses which kill the amebas. In a solution of 1:10,000 it is amebicidal at once, at 1:100,000 in two minutes. Experience indicates that by its use amebic abscess of the liver can be prevented and even cured. Sometimes it is difficult to distinguish between amebic and bacillary dysentery, especially, of course, in the absence of good laboratory facilities; under such circumstances emetin may be of diagnostic value because improvement follows its use in two or three days if the case is amebic. According to Ross, the slightest suspicion of dysentery in Mediterranean troops now calls for the immediate injection of emetin on the chance that it will destroy an enemy whose presence there is ground only to suspect. Like the few, very few, other specifics we have, emetin has its limitations. The promptness and completeness of its specific curative action stand in direct proportion to the acuteness of the attack; in neglected cases in which the destructive trenching and mining of the intestinal wall are very extensive and associated with mixed secondary infections, and in so-called compound cases of dysentery, the emetin treatment may fail of complete success. Emetin also seems powerless against the encysted ameba and hence of but comparatively little influence in ameba carriers. As a direct cure for pyorrhea it seems to have failed, not because it does not act on the amebas which are found in the pyorrheal pockets, but because pyorrhea is not caused by amebas, as asserted by some prematurely. But take it all in all there are few drugs, if any, that have such an interesting, eventful and withal successful history as ipecac.

SOME FACTORS IN MILK PRODUCTION

Recently the view that the mammary gland tends to manufacture a specific product, milk, which is in no sense a mixture of unaltered food components absorbed in part unchanged and reexcreted in the same form, was discussed in THE JOURNAL. This must not be interpreted as meaning that milk production is in ultimate analysis entirely independent of the diet. If constructive units of a suitable sort are entirely lacking in the ration, they will either be derived from the body tissues themselves or milk production must ultimately fail. In this sense the quality of the proteins furnished to a lactating individual is of decided moment, but whatever the protein may be, the milk proteins produced are representative and characteristic so long as they are produced at all.[1]

Again, in the case of the fats, it is doubtless true that abnormal butter has been produced by feeding a cow large quantities of vegetable oils, such as cottonseed oil, linseed oil and sesame oil; but such feeding conditions cannot be regarded as normal. It has been pointed out that the food fat does not go over into the milk so readily in any considerable quantity without "metabolic supervision," as many are inclined to believe[2] The mammary gland attempts at least to secure a characteristic output despite the occasional "escape" of unusual components Some of these, like butter color, doubtless owe their presence in the milk to the accident of their unusual solubility in fats rather than to any other special selective circumstance

[2] Rogers, Leonard: Dysenteries: Their Differentiation and Treatment, New York, Oxford University Press, 1913.

[1] The Relation of Proteins to Milk Production, editorial, THE JOURNAL A. M. A., Nov. 4, 1916, p. 1374.

If further evidence of the persistence of the mammary gland to produce the normal milk constituents under unusual conditions were demanded, it might be found in recent investigations at the University of Missouri[3] The data derived from a study of the influence of the plane of nutrition on the mammary functions seem clearly to warrant the general conclusion that normal milk and butter are to be expected when the cow is on a supernormal plane of nutrition as well as when the plane of nutrition is normal, provided there are no other influencing factors, such as specific feeds

It has been remarked that underfeeding, for a time at least, need not alter the character of the milk so long as the body stores can be drawn on for needed constructive units Eckles and Palmer have now shown, on the other hand, that overfeeding, that is, an increase in the plane of nutrition above normal, fails to raise the flow of milk above the normal except in certain limited cases, and in these to a small degree at most These facts bring to mind the contention that the secretion of milk may be essentially under control of hormone stimulation, with nervous factors participating in a minor degree The Missouri investigators believe that their newest results admit of interpretation on the basis of this current hypothesis They summarize them as follows The chemical stimulus for milk secretion is the predominating stimulus immediately following parturition, and continues to be so for a period of time, the limit of which is not yet brought out The chemical stimulus for milk secretion is the stimulus which fixes the maximum milk flow for each individual animal It is more or less fixed for each individual Just what controls the extent of the stimulus for individual animals is not as yet known Our present knowledge indicates that it is a problem of heredity as well as one of physiology The chemical stimulus for milk secretion received at parturition is more or less independent of the plane of nutrition of the cow Stated in another way, this stimulus neither requires a constant food supply from without the organism, nor is it increased by an excess food supply from outside the organism Experimental evidence indicates that the chemical stimulus is so strong immediately following parturition that the milk flow will continue at a normal level for an astonishingly long period of time, at the expense of the body, with a food supply entirely inadequate for this purpose It is not possible to increase the chemical stimulus for milk production immediately following parturition by means of an excess food supply

As the lactation period advances, the chemical stimulus for milk secretion is gradually replaced by a stimulus with entirely different characteristics Eckles and Palmer have designated this as the nervous stimulus The nervous stimulus for milk secretion is entirely dependent on the plane of nutrition of the cow Stated in other terms, this means that as soon as the nervous stimulus for the secretion of milk predominates, the milk flow is readily affected by a subnormal plane of nutrition, and can, moreover, be partially restored to its former figure by increasing the plane of nutrition These researches presented by investigators in the field of agricultural sciences are not merely of interest because they bear on the production of food for man in the adult and particularly in the infant period Lactation in the human species is not so readily subjected to accurate experimental observation, hence the knowledge of the possible factors which play a dominant part in the physiology of human milk secretion must be derived from other sources than observations on man The conditions under which human lactating individuals ordinarily exist are, of course, widely different from those pertaining to the domestic animals, yet physiologic principles are often so fundamental in character that the environmental factors are incidental rather than essential, and broad principles are not necessarily vitiated by differences in species, locality, or habits of living

THE VENEREAL DISEASE PROBLEM—I

The sanitary problem of the venereal diseases is at present receiving wide consideration In the countries which are at war, the importance of the subject is emphasized by the ravages which these diseases always produce among troops in war time, and by the anxiety concerning the great increase in prevalence of the venereal diseases which experience has shown follows the return of troops at the end of war But another reason for the present interest in the subject is the opinion, which is evidently becoming widespread among those who are most conversant with the venereal diseases, that in early diagnosis and treatment lie effective measures for the control of these diseases, whenever governments may be persuaded to undertake a thoroughgoing attack against them Among organized efforts which have recently been made against venereal diseases, those of England, Germany and Australia are outstanding The efforts in England are, perhaps, of the greatest practical interest to us because England's social and political conditions approach most closely to ours

The modern English attempts to attack the problems of prostitution and venereal disease may be briefly reviewed, for particularly in their failures they offer instruction to us These attempts may be said to go back to 1864 In that year the contagious disease act was passed, which provided for the regulation of prostitution and medical examination of prostitutes Amendments to this act were passed in 1866 and 1869 The acts never had the support of the British public They were abhorrent to the public sense of social decency, and were opposed on moral grounds by an influential part of the community They were thus necessarily ineffective for the purposes for which they were passed Opposition to them resulted in a royal commission in 1870 which recommended the abolition of the examination of prostitutes In 1879 the House of Commons appointed a committee to consider the subject This committee presented a divided report, a majority being against the repeal of the acts In 1883 the agitation resulted in the abolition of the examination of prostitutes, and in 1886 the contagious disease acts were repealed From 1886 to 1916 the English government has made no national effort to attack the situation

---

[3] Eckles C H, and Palmer, L. S The Influence of the Plane of Nutrition of the Cow upon the Composition and Properties of Milk and Butter Fat Research Bull 24, Univ of Missouri Agr Expt Sta 1916

In Great Britain, however, as elsewhere, there has been growing up a strong feeling that society must make an organized effort against the venereal diseases In 1898 an insistent demand was made for the appointment of a royal commission to inquire into the prevalence and effects of the venereal diseases In 1899 resolutions, proposed by the British Medical Association, calling for a full inquiry into this subject were passed by the Brussels International Medical Congress Since that time there has been considerable agitation in England, but government authorities have showed reluctance to take up the problem, apparently feeling that the object which was desired was the reenactment of acts for the regulation and examination of prostitutes All of these efforts were fruitless until 1913 In that year, shortly before the meeting of the international congress, public agitation on this subject was started in London by a small group of leaders, and a vigorous resolution on the subject was passed by the International Medical Congress at its meeting in London in 1913 These efforts succeeded in obtaining finally the appointment by the British Parliament, Nov 1, 1913, of a royal commission[1] for the investigation of venereal diseases This commission did not publish its report until March 2, 1916 It devoted more than two years to the investigation of the subject It examined eighty-five expert witnesses, whom it asked 22,296 questions It had as witnesses men who could speak authoritatively on the various topics under discussion, including well known continental authorities on venereal diseases When it is added that the personnel of the commission represented the best British intelligence in its field, it may be seen that the findings of the committee are of great importance, and its report entitled to our most respectful consideration

The commission apparently hesitated about making its report in war time, for fear that with more pressing business it might be overlooked The importance of the subject, however, constrained the commission to make its report in the midst of the nation's preoccupation As a matter of fact, the issuance of the report at this time proved to be particularly opportune The importance of the venereal diseases was brought home to the country by the war in a way in which it could not have been done at any other time This is shown by the fact that the essential, and most of the detailed, recommendations of the commission were carried into legal effect by action of the English Local Government Board, July 13, 1916—four months after the report was presented

The report of the commission is restrained and temperate, and marked by sound appreciation of the practical difficulties of the problem It shows not a suspicion of hysteria, but, on the contrary, is distinguished by the practical common sense which it has brought to bear on all of the aspects of the subject The commission made no effort to consider prostitution alone, and it makes no suggestions as to the remedying of that social defect It did, however, consider the question of registration and examination of prostitutes, and it sought the advice of continental medical authorities among others on this point

The report can be briefly summarized It holds that registration and medical examination of prostitutes are ineffective as a sanitary measure It recommends against compulsory notification of venereal diseases at present It urges the importance of education as to the seriousness of venereal diseases and the dangers of their transmission It recommends the encouragement of well considered efforts for inculcating sexual restraint It puts its great emphasis, however, on the therapeutic attack on syphilis, and by its recommendations indicates its opinion that in this lies the hope of the sanitary control of the plague It is here that the report is definite and positive in its recommendations In early and continuous treatment it finds the effective weapon against the venereal diseases, and in widespread state provisions for the diagnosis and treatment of the venereal diseases a practical way leading to a solution of the difficult problem which these diseases present

---

[1] The purpose of the commission was said to be 'To inquire into the prevalence of venereal diseases in the United Kingdom their effects upon the health of the community, and the means by which those effects can be alleviated or prevented it being understood that no return to the policy or provisions of the Contagious Diseases Acts of 1864 1866, or 1869 is to be regarded as falling within the scope of the inquiry ' The commission was formed as follows Lord Sydenham of Combe F R S (chairman) noted for his public service, the Right Hon Sir David Brynmor Jones, K C, M P Sir Kenelm E Digby and Sir Almeric FitzRoy representing the legal and official side of the commission Sir Malcolm Morris, F R C S Edin Mr James Ernest Lane, F R C S Eng Sir John Collie M D Dr Arthur Newsholme, Dr F W Mott F R S and Mrs Scharlieb M D noted as medical *workers in this field* Canon J W Horsley, the Rev J Scott Lidgett, D D Mr Philip Snowden M P and Mrs Creighton religious and service workers and Mrs Burgwin experienced in the care of the feebleminded The secretary of the commission is Mr E R Forber, an official of the Local Government Board The London Lancet notes that the only omission from the committee which calls for notice is the absence of any member able to give first hand advice on the conditions in the military and naval services

The report thus offers no startling findings It presents no new remedy It has, however, considered with great thoroughness all of the practical aspects of the problem, weighed them with unprejudiced judgment, and with quiet courage made the radical recommendation that the English government shall provide universal opportunities for the diagnosis and treatment of the venereal diseases It submits a detailed plan for carrying out its recommendations as regards providing opportunities for diagnosis and treatment The various recommendations of the report cannot be considered in the brief space of one notice They are so important and so interesting that we shall revert to them later

THE BOAS-OPPLER BACILLUS

About twenty years ago, Boas and Oppler[1] described the frequent occurrence of a long bacillus in the gastric contents of persons with carcinoma of the stomach This appearance of what has since been known as the Boas-Oppler bacillus was repeatedly verified It was found that the micro-organism cannot thrive in the presence of a normal gastric reaction due to hydrochloric acid, and it seemed to require a marked stagnation of the stomach for suitable development As decreased gastric secretion of hydrochloric acid and diminished motility of the stomach commonly exist in cases of cancer of this organ, suitable opportunities are afforded for the growth of the Boas-Oppler bacillus

In the minds of many practitioners, the finding of this micro-organism in stomach contents has come to have an almost specific diagnostic significance Without knowing anything of its real origin and its bacteriologic relationships, they have endowed it with a special pathognomonic importance which has never been entirely warranted and has lost much of its earlier significance in the light of present knowledge Long ago it was pointed out not only that the Boas-Oppler bacillus may be found at times in normal stomachs but, further, that it seemed to be related to the lactobacilli in general Heinemann of Chicago, in particular, demonstrated that bacilli belonging to what is now familiar as the *B bulgaricus* group of organisms may be found in samples of gastric juice from healthy as well as carcinomatous stomachs The close relationship of the Boas-Oppler bacillus with the lactobacilli, to which so much prominence has been given of late in relation to sour milk therapy, if not its actual identity with them, must be accepted

Bacilli of the *B bulgaricus* group are widely distributed in nature They have been found in fodders and foods serving for animal and human consumption, in soil, in feces, in saliva — to enumerate only a few of the sources In a recent study of the lactobacilli, Heinemann and Ecker[2] remind us that since these micro-organisms have been found in saliva and feces under normal conditions, it would be surprising if they did not exist normally in the stomach Their presence in the digestive tract is a natural result of their frequency in foods, especially milk and milk products Furthermore, this group of bacilli is able to resist a relatively high degree of acidity, and to survive where other bacteria are largely destroyed Consequently the hydrochloric acid of the stomach is not absolutely destructive to them, although it undoubtedly restrains their growth

It seems logical to assume further, with Heinemann, that reduction in the amount of gastric acid or its absence will permit growth of bacilli of the bulgaricus type — an assumption which may readily explain the finding of any lactobacilli in large numbers in cases of gastric carcinoma If this is true, they may be expected to be present in any pathologic condition which reduces the normal acidity of the gastric juice Such is, in fact, the case The presence of large numbers of the Boas-Oppler bacilli which gain access to the alimentary tract with the food is merely an indication of a reduction of the normal hydrochloric acid content, whether this is due to gastric ulcer, gastritis, pernicious anemia, or gastric carcinoma and possibly other pathologic conditions Any specific diagnostic import beyond this is no longer tenable

Recent investigations of the Boas-Oppler bacilli[2] make it probable that they are familiar lactic acid-producing organisms which occur in saliva and in the contents of the digestive tube They are said to be common in the feces of bottle-fed infants, but relatively scarce in the alimentary contents of those which are breast fed The typical lactobacilli have also been found in the decayed contents of teeth from which desiccated mucus has been removed, suggesting that the *Streptothrix buccalis*, long believed to be associated with dental caries, also may be closely related to the organisms here under discussion All of these facts warn against attaching too much specific significance to the occasional finding of lactobacilli in the gastric contents

---

Disease and the Chinese —It is commonly said that diabetes is unknown in China, yet a recent incomplete investigation brought to light over 200 cases Nervous diseases are accounted rare among the Chinese, yet even a short experience has shown their incidence, at least in Changsha, to be as great or greater than in this country The idea of easy childbirth and freedom from puerperal and postpartum infection is contrary to much experience and certainly is not supported by the Chinese aphorism that a woman in labor has one foot in the grave The group of neuroses, functional digestive disorders, gastric and duodenal ulcer, malignant, nutritional and constitutional diseases are without doubt vastly more prevalent in China than accredited to be So we might go through the list We must challenge every statement of a superior racial vitality in the Chinese on the ground of superior resistance to disease, until such time as demonstrable scientific proof and controlled statistics are presented in its favor — Dr Alfred C Reed, *Scientific Monthly* January, 1917

EGGS AND THE HEN

Next to milk and cereals, eggs probably play the most prominent part in the special dietaries of the sick, because of the advantageous composition of eggs from the standpoint of their nutritive value Not only do they contain representatives of a variety of types of foodstuffs, but they also are palatable and lend themselves to culinary manipulation so as to meet a great diversity of tastes Even most vegetarians are willing to include eggs in their list of acceptable food products These facts help to account for the cry which has arisen at the advancing price of eggs, the much debated cause of which we may discreetly pass over in silence *In view of the situation, it is not* without interest, however, to learn what hens can do to meet the emergency The fourth annual international egg laying contest conducted by the Storrs Agricultural Experiment Station of Connecticut included 1,000 birds which laid an average of 152 eggs per hen during the year One enterprising hen laid sixty-four eggs in sixty-four days Other good individual records, which are not intended to represent the acme of laying possibilities, showed a production of more than 250 eggs per year As every one knows, the egg production is not uniform at all seasons of the year, the maximum occurring in the spring and summer months Dietotherapy and institutional dietetics need to bear these facts in mind — or suffer the economic consequences

PROVING "INTENT"

A brief item appears in this week's Propaganda department on the failure of the federal authorities successfully to maintain the criminal charge against Brinkler, the self-styled food expert, of using the mails to defraud Few realize the tremendous difficulties that confront the prosecution in cases of this kind The Office of the Solicitor of the Post-Office Department under both past and present administrations, has done notable public service in putting out of business some of the most pernicious swindles perpetrated on the American people Samuels, with his "eye drops" cure-all and Moses, the "Oxypathor" faker come to mind as cases in which the government successfully maintained criminal action against the individuals Moses and Samuels are now in the federal penitentiary The great stumbling block in the way of the federal officers is that requirement in the law which makes it necessary for the prosecution in such instances to prove not only that a fraud has been perpetrated, but also that the man engaged *in the business* knew that he was defrauding In other words, the government has to prove "intent" To keep out of the penitentiary it is only necessary for quacks of the Brinkler type to show with some plausibility that they humbugged the public in good faith in a mistaken belief in their own panacea When such an attitude can be maintained, a verdict of "not guilty" is a foregone conclusion Under these conditions, the greater the ignorance of the individual prosecuted, the easier it is to convince the jury that the man really believes in his own magic, and the more difficult the problem of putting him where he will cease to be a menace to the public health Of Brinkler's ignorance, his "literature" and other material are the most palpable evidence This fact, rather than any failure on the part of the federal officials to prove the inherent falsity of Brinkler's claims, is probably responsible for his acquittal It is a pity that there is not a more general recognition of the principle enounced by Goethe that "nothing is more dangerous than active ignorance"

NATIONAL LEPROSARIUM BILL PASSES SENATE

As noted in our news columns in this issue, the passage of the bill providing for a national hospital for lepers marks the successful completion of efforts that have been made for a number of years[1] to secure the establishment by Congress of a national institution in which may be gathered, for care and treatment, those unfortunate persons who may be infected with leprosy The number in any one state is too small to justify the establishment of state institutions The popular horror of leprosy and the absence of adequate provisions for the care of lepers have led in the past to extremely cruel and inhuman incidents which, it is hoped, will in the future be impossible The removal of infected persons forming possible centers of infection will doubtless tend to check the spread of the disease, while rigid quarantine inspection will halt all immigrant lepers at our ports of entry The passage of this bill is a distinct achievement for public health, and marks not only a growing disposition on the part of Congress to legislate constructively on public health questions, but also the constantly expanding importance and scope of the United States Public Health Service To Senator Ransdell of Louisiana, chairman of the Senate Committee on Public Health and National Quarantine, and to Mr Adamson of Georgia, chairman of the House Committee on Interstate and Foreign Commerce, is due a large share of the credit for the success of this measure

"MUCKRAKING" IN MEDICINE

"One of the things that has made today a bolder, better time than what Mr Ade calls the 'yappy seventies' is muckraking Call it muckraking if you like call it honest journalism if you choose—the power to call men and things by their real names has shot our fair and colder nation several inches closer to the far-famed millennium"

This from F P A's "Conning Tower" in the New York *Tribune* As is usual when he philosophizes, Mr Adams scores a bull's eye While the paragraph quoted applies to lay rather than medical journalism, the thought expressed is applicable to both The "muckraking" with which THE JOURNAL has been charged has, to paraphrase Mr Adams' statement, made medicine today a bolder, better profession than it was in the "yappy seventies" And, extending the comparison still further, the power of organized medicine to call men and things by their real names has brought our profession appreciably closer to the scientific millenium

THE FATE OF PHENOLSULPHONEPHTHALEIN

The employment of the phenolsulphonephthalein test as an index of renal functional capacity is rapidly becoming generalized No doubt one of the reasons for this is, as was recently pointed out in The Journal,[1] that it is the method which most readily lends itself to use in general medical practice The interpretation of this test has hitherto been based on the supposition that the retention of more than from 20 to 40 per cent, that is, the appearance of less than from 60 to 80 per cent in the urine within two hours after injection, is an indication of deficient functional activity According to Kendall,[2] phenolsulphonephthalein may in certain experimental conditions be destroyed in the body, and therefore not appear in the urine, although the kidneys may be functioning normally He is inclined to attribute this destruction to the reducing action of an enzyme (reducase) Whatever the mechanism involved, these observations are of importance Should they be confirmed, it will be necessary to ascertain whether or not this phenomenon occurs clinically in the human being and, if so, in what class of cases and to what extent We may ultimately be obliged to limit our interpretation of the results of this test to this that an excretion of from 60 to 80 per cent—that is, a positive result—within two hours after the injection of the phenolsulphonephthalein is evidence of satisfactory renal activity

NOSTRUM ADVERTISING AND THE AGENCY LEVERAGE

The ramifications of the fraudulent "patent medicine" business are many The acceptance of advertising from such concerns by small country newspapers is not always an indication of a low ethical standard of advertising, at least not wholly so One of the developments of modern business is the advertising agency, to which many concerns, instead of attempting to handle their own contracts, turn over their advertising business These agencies place the advertisements in such publications as their special knowledge and judgment suggest will bring the best returns to their clients Large agencies, having the power of dispensing advertising largess, naturally possess no little influence with publishers Supposing, then, that the manager of a large agency is financially interested in a fraudulent "patent medicine" business whose advertising he handles — and there are some such cases Suppose, further, that he submits an advertisement of the nostrum in which he is interested to a country newspaper publisher who tries to keep his advertising pages clean If this country publisher rejects the "patent medicine" copy, he puts himself in the position of offending a man who has the power to send to him, or withhold from him, much reputable advertising business during the course of the year As one of the big advertisers of the country has said "Naturally publishers — particularly the little fellows — hesitate' to offend a concern which sends them so much business even though they hate to accept this particular kind of advertising" When next you feel like "jumping on" the publisher of your local paper because of some particularly flagrant nostrum advertisement, find out before you do so just how much economic pressure is being exerted, directly or indirectly, to make him accept such advertising

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals, education public health, etc)

CALIFORNIA

Typhus at Clovis—Two persons with typhus fever have been discovered in a Mexican camp at Clovis and have been removed to the County Hospital for treatment. They recently came from Mexico to the camp in Clovis The camp has been quarantined

Medical Lectures—The lectures of the thirty-fifth popular course given in Lane Hall, under the auspices of Stanford University Medical School, will be as follows

February 9 Poliomyelitis" Dr William C Hassler, Health Officer of San Francisco

February 23, The Importance of Proper Habits of Carriage as a Basis of Health ' Illustrated Dr Harry L Langnecker, Clinical Instructor in Orthopedic Surgery, Stanford Medical School

DISTRICT OF COLUMBIA

Podiatry to Be Regulated in the District.—A bill for the regulation of the practice of "podiatry" in the District passed the Senate, January 25, and now goes to the House In the bill "podiatry" or chiropody ' is defined as the surgical or medical treatment of all ailments of the human foot, except the correction of deformities requiring the use of the knife amputation of foot or toes, or the use of an anesthetic other than local The bill does not interfere with physicians in the discharge of their professional duties The board of medical supervisors is charged with the duty of carrying the act into effect A schedule of preliminary and technical education is laid down for new applicants, progressing gradually in requirement until 1920 when the applicant must have a four-year high school course or its equivalent and must be a graduate of a podiatry school acceptable to the board of medical supervisors

ILLINOIS

Change Meeting Date—The Illinois State Medical Society has changed the date of the annual meeting from May 15 to 17, to May 8 to 10

Communicable Disease—Three cases of spinal meningitis have developed at the Great Lakes Naval Training Station, with one death The liberty privilege for recruits has been temporarily suspended and all the apprentice seamen are under observation

Infirmary Given to State University—Dr Edmund J James president of the University of Illinois, announced, on January 25, that Hon William B McKinley, Champaign, congressman from the Nineteenth District, has given bonds and stocks valued at $120,000 to the university for the establishment of an infirmary for the use of the students and faculties of the institution

Chicago

New Research Laboratory—The Chicago Medical Society has asked the president of the county board for a pathologic and research laboratory building and a new morgue at Cook County Hospital, at a cost of $750 000

Ambulance Corps to Be Formed—An ambulance corps of the medical students of the University of Chicago is in process of formation under the direction of Dr H Wernicke Gentles, in local charge of the work of the American Red Cross

Trachoma in Ohio.—The state department of health has sent a questionnaire to all ophthalmologists practicing in Ohio with a view to determining the foci of infection of trachoma.

New Officers.—Toledo Academy of Medicine: president, Harold J. Morgan; vice president, Dr. Charles Lukens; secre-

[illegible] Health [illegible] [illegible] rected [illegible] Vital [illegible] Health Depart[illegible] present undue [illegible] the value [illegible] Columbus of [illegible] status of [illegible] that in only [illegible] regularly [illegible] benches and [illegible] W. H. Dittoe and [illegible] Dr. Roscoe P. [illegible] Three Deaths and a [illegible] Housing Con[illegible] tion was led by [illegible] Cincinnati. The senti[illegible] should be replaced by [illegible] all cities of Ohio were [illegible]

Cincinnati

Personal.—Dr. John F. Bencke, who has been critically ill, [illegible] reported convalescent.——Dr. Louis [illegible] with the Italian Red Cross.——Dr. Wade [illegible] recently returned from the Rockefeller Foundation [illegible] South America, was operated on for appendicitis [illegible] on January 2, and is doing well.

PENNSYLVANIA

Health Conference.—A conference of physicians will be held February 16 at the state capitol, Harrisburg, under the auspices of the Division of Industrial Hygiene and Engineering of the Department of Labor and Industry.

Charity Budget Increased.—The increased cost of living and the growing population have caused a material increase in the sum recommended by the State Board of Public Charities for appropriations for state, semistate and private institutions. Two years ago the total recommended was $12,142,673.48, while this year's board recommends $15,041,884.

Medical Society Against Free Practice.—A pledge from all new members against free treatment in or out of hospital dispensaries for patients able to pay will be exacted hereafter by the Philadelphia County Medical Society. Resolutions endorsed by the society are as follows:

That physicians who are now working without remuneration in hospital dispensaries request the management of such to institute an efficient system of investigation of the social and financial status of each patient admitted, and that each such patient be supplied with evidence of this investigation before presentation to the physician for second treatment

Philadelphia

New Ambulances—Two new ambulances are soon to be in service with the American Field Ambulance Corps at the French front as a result of donations received by the American Ambulance Hospital Committee of the Emergency Aid

New Officers—At the annual meeting of the Philadelphia County Medical Society, January 17, the following officers were elected president, Dr Henry D Jump, vice president, Dr Moses Behrend, associate vice presidents Drs Mitchell P Warmuth Andrew Callahan, Louis E Barlow, Samuel McClary III, George E Levis Robert N Downs, Jr, and Aaron Bray secretary, Dr William S Ray, and treasurer, Dr Edward A Shumway

Public Lecture Course for Women—The lectures during February in the public lecture course given by the faculty of the Women's Medical College of Pennsylvania will be as follows

February 7 Principles of Nutrition Dr Martha Tracy
February 14 Food and Efficiency," Dr Martha Tracy
February 21 *Health Problems of Girls and Women,' Dr Ella B* Everitt
February 28 Social Diseases, Dr Frances C Van Gasken

Personal—William Curtis Farabee, curator of the American Section of the University of Pennsylvania Museum who recently returned after three years of exploration in the Amazon Valley was awarded the Elisha Kent Kane Medal by the Geographical Society of Philadelphia, January 19——Dr Frank C Abbott, who recently returned after fourteen months on the western war front delivered an address before the Ethical Culture Society, January 14, on War Experiences in Europe" Dr Abbott expects to return shortly——Dr Francis V Gowen has returned after several months as head surgeon in a hospital at Bretigny-sur Orge, France

WASHINGTON

Hospital Fire—Fire in St Luke's Hospital, Spokane, January 21, caused damage estimated at $50,000

Personal—Dr Edward A Rich has been appointed health officer of Tacoma and Dr Jonathan E Henry has been continued as city chemist and bacteriologist

New Officers—At the annual meeting of the Spokane County Medical Society, January 11 the following officers were elected president, Dr Herman P Marshall, vice presidents, Drs Peter Reid Rufus I Newell and Arthur E Johnson, secretary Dr William Sullivan and treasurer, Dr Alexander R Lundgren

WEST VIRGINIA

Paralysis Epidemic Checked—The epidemic of infantile paralysis at Elkins has apparently been checked There have been seventeen cases reported, with two deaths

Society Activities—On February 2, the Ohio County Medical Society Wheeling held a joint meeting with the board of education of Wheeling, at which Dr Edwin A Peterson, in charge of the medical department inspection and physical education in Cleveland delivered an address

Epidemic of Disease—Dr Samuel L Jepson, commissioner of health has issued an order suspending the quarantine against the city of Elkins, where infantile paralysis has been prevalent——On account of the presence of infantile paralysis in Fairmont, the Marion County Medical Association has recommended that all schools, except the State Normal School, be closed, and that children under 16 years of age be not allowed to attend public gatherings

WISCONSIN

Personal—Dr Arthur S Loevenhart of the University of Wisconsin has been under treatment in a hospital for an attack of nephritic colic

Smallpox—The Mammoth Paint Creek Construction Camp, where 500 men were employed, was suspended January 19, owing to the outbreak of smallpox at Camp Wisota

Milwaukee Physicians Elect New Officers—At the annual meeting of the Milwaukee Medical Society, January 9, the following officers were elected president, Dr Daniel Hopkinson, vice presidents, Drs George A Carhart and Alfred L Kastner, secretary, Dr Oscar Lotz, and treasurer, Dr Joseph P McMahon

Hospital Notes—The state board of control has endorsed the Onalaska site for the proposed $50,000 La Crosse County Tuberculosis Sanatorium——The Waukesha County Board has purchased, for $16,500, a site near Pewaukee for a tuberculosis sanatorium——St Francis' Hospital, La Crosse, at a cost of $90,000, has added to its building two new wings three stories in height The entire hospital has been remodeled

CANADA

Provincial Supply of Antitoxin—The Provincial Board of Health for Ontario will supply diphtheria and tetanus antitoxin, antimeningitis serum, smallpox vaccine and Pasteur preventive treatment for rabies, and mixed typhoid and paratyphoid vaccine free to the public all over the province The aggregate cost for the year will be $40,000, or about one fourth of the cost under commercial conditions All these products except typhoid vaccine are obtained from the University of Toronto

Personal—Surg-Gen Carleton Jones will shortly relinquish his position as director of the medical services for Canada and become inspector-general between Canada, Great Britain and France He will be succeeded by Col Gilbert Lafayette Foster, formerly assistant director of medical services in the Toronto Military District——Dr Walter W White, ex-president of the New Brunswick Medical Society, was given a dinner by members of the profession in St John N B on his fifty-fourth birthday——Dr J T Boyd, superintendent of the Kingston (Ont) General Hospital, has resigned owing to ill health——In the new cabinet of the British Columbia government two doctors are included Dr James H King minister of public work and Dr John D MacLean, Provincial Secretary and Minister of Education

GENERAL

Warren Prize Awarded—The Warren triennial prize for 1916, amounting to $500 has been awarded to D Noel Paton Glasgow Scotland, for his essay entitled "The Parathyroids"

Sale of Anhalonium to be Regulated—The Senate passed a bill, January 25, to amend the Harrison Narcotic Law to cover anhalonium mescale or muscale buttons, and pellote. The bill now goes to the House for action

Tri-State Association to Meet—The nineteenth annual session of the Tri-State Medical Association of the Carolinas and Virginia will be held in Durham N C February 21 and 22, under the presidency of Dr J Allison Hodges, Richmond, Va

Industrial Hygiene Standards—Surg Joseph W Schereschewsky U S P H S in charge of the field work for occupational diseases, has been making an investigation of the health conditions of steel workers in Pittsburgh to provide the government with information for minimum standards of industrial hygiene

Reinstatement Sought—The reinstatement of Dr Bert R Huntington as first lieutenant, M C, U S Army, is sought through special legislation, the United States Senate having passed a bill for that purpose, January 25 Dr Huntington was examined for promotion to a captaincy in 1914, but the board made an adverse report and he was therefore discharged from the army, March 24, 1914

Prize Offered by Industrial Medical Association—The American Association of Industrial Physicians and Surgeons offers a prize of $100 for the best thesis on any subject relating to industrial medicine and surgery by any undergraduate medical student of the United States The thesis must not contain more than 5,000 words and must be in the hands of Dr Harry E Mock 122 South Michigan Avenue Chicago, secretary of the association, on or before May 1, 1917

The American Journal of Syphilis—A new quarterly publication, the *American Journal of Syphilis,* has just issued its first number It is a pretentious journal of 260 pages, with an elaborate staff of editors and editorial collaborators, about 100 of them The cover page bears an appropriate statement by Sir William Osler

> Know syphilis in all its manifestations and relations and all other things clinical will be added unto you

Several of the articles are excellently illustrated, and a symposium of three papers is devoted to syphilis of the stomach The social side of the subject is not neglected, as evidenced by an article by Dr William Allen Pusey on the "Sanitary Attack Upon Syphilis," and one by Dr Henry H Hazen on "Teaching of Syphilis"

Bequests and Donations—The following bequests and donations have recently been announced

For the establishment of a home for convalescents at Brewster, N Y, $75 000 by the will of Mrs Arietta Crane Reed

St. Peter s Hospital Brooklyn $5,000, by the will of Ellen McAree

Columbia University New York, for the endowment fund of the Sloane Hospital for Women $75,000, from Mrs William Douglas Sloane

Associated Charities of Newburyport, Mass, the income from $50 000 and the Anna Jaques Hospital Newburyport, the income from $100 000 for the support and maintenance of the antituberculosis department, by the will of Julia M Mosly, Newburyport

Misericordia Hospital, Philadelphia, a contingent bequest of more than $4,000 from the estate of Mary E Grandle

Personal—Passed Assistant Surgeon John B Kaufman U S N, lately in charge of the hospital school of instruction at Newport News, Va, has been placed in charge of the hospital school to be established at Great Lakes Ill——Senior Surgeon Henry R Carter assistant surgeon general, U S P H S, and head of the Malaria Investigation Bureau has gone to Colleton County, S C, to study the malaria conditions in Broxton Township——Sanitary Engineer William D Wrightson, U S P H S, head of the mosquito campaign in Baltimore has accepted a position as superintendent of the construction of the Capitol Filterage Plant to be built in Lima Peru by the Peruvian government, and has sailed for his new post of duty

Typhoid Death Claims Settled—The Illinois Industrial Board has completed the settlement of fourteen of the eighteen death claims against the Elgin National Watch Company as a result of the recent typhoid epidemic among its employees This epidemic, amounting to over 100 cases of typhoid, was due to the contamination of the drinking water furnished employees The settlements made so far aggregate over $30,000, or an average of a little more than $2,000 each The four remaining claims will probably be settled during the next month In addition to the settlement of these death claims, the Elgin National Watch Company has voluntarily paid over $55,000 for medical and hospital attendance in an effort to control the typhoid epidemic The case is an important one as tending to establish the principle that typhoid fever is under some conditions, a disease consequent on occupation

National Leprosarium Bill Passes Senate—The bill providing for a national hospital for lepers has been discussed in THE JOURNAL repeatedly during the past year This bill simultaneously introduced in the House and Senate passed the House, May 15, 1916 It appropriated $250,000 for a national home for lepers, either on a site acquired by purchase or on any abandoned government reservation suitable for the purpose, the hospital to be under the regulation of the surgeon-general of the U S Public Health Service and to be for the care and treatment of any person afflicted with leprosy who presents himself voluntarily, or for any who may be apprehended under the U S Quarantine Acts or for any one consigned to the home by the proper health authorities of any state January 25, the bill was called up on the calendar in the Senate As passed by the House, the bill provided an addition to the pay of any medical officers detailed for service in the leper hospital of one half of their regular pay, in the Senate bill the additional pay was one quarter Senator Ransdell of Louisiana, chairman of the Senate Committee on Public Health and National Quarantine, in order to expedite the passage of the bill, moved to substitute the House bill for the Senate bill and secured its passage by unanimous consent.

WAR NOTES

Praise for American Ambulance Men—In an official comendation of the Second American Automobile Ambulance Section on duty in France Robert MacCreary, East Aurora, N Y, and Marcellus Wild, Rochester, N Y, have been named 'for their really exceptional devotion to duty" H C Hoskier and Marcel du Casse, New York, and L H Northrop Winnipeg, Man, received individual mention entitling them to the *Croix de Guerre*

Contributions to Expeditions Committee Fund—Hon Herman A Metz, Cleveland, has contributed $20 000 to the American Physicians Expeditions Committee

Unit Sails for England—The following physicians sailed, January 20, on the *New York* for service at hospitals in England and base hospitals in France Drs James V Ricci, Providence R I, Jerome F Potts, Washington, D C, William M Findley, New York, Frederick A Simonds Wakefield, Mass, J Franklin Harvey, Boston, Charles Curtis Allen Topeka, Kan, Leo Thomas Kewer Waverley, Mass, Carl Edwin Allison Wakefield, Mass, Charles F Gormly Providence R I, William H Mackay, Worcester, Mass, and Audley C Sanders Boston

FOREIGN

Cholera and Typhus in Palestine—The Women's Zionist Organization of New York announces that cholera and typhus have claimed so many victims among physicians in Palestine that few medical men remain on duty The organization asks $75 000 for the equipment and maintenance of a medical unit for one year

New Medical Era for China—President Harry Pratt Judson of the University of Chicago in an address before the World Problem Institute of the University of Chicago, January 8 stated that it is proposed that a medical training school be erected in Peking Around this school a chain of hospitals will be established A second school will be organized at Shanghai Both of these institutions are to be financed by the Rockefeller Foundation

Meetings of Internists in Europe—The ninth quadrennial Scandinavian congress for internal medicine was to have been held in Finland this spring but the war prevents Arrangements have now been made for the meeting to be held at Copenhagen in August 1917 The subjects appointed for discussion are Importance of Dieting in Treatment of Insufficiency of the Heart and Kidneys," and "Neurasthenia in Relation to Psychopathic Conditions" V Scheel, Bispebjaerg Hospital Copenhagen, is the secretary——The twenty-third annual meeting of the German internists is planned to convene at Wiesbaden in the coming April The main addresses announced are on 'Nutrition in War," "The Constitution as a Cause of Disease," and "The Rarer Infectious Diseases Encountered During the War" W Weintraud, Rosselstrasse 20 Wiesbaden is the secretary The announcement of this meeting specifies that communications for it will not be accepted if their essential content has already been published

Epidemic of Malignant Malaria in Mexico—The *Bulletin* of the Mexican National Board of Health states that two health officers were sent to Tehuantepec, as yellow fever was said to be prevailing there, many dying from a sickness with much vomiting of blood and hemorrhagic stools They found the trouble to be malignant malaria the parasites of the tertian phase numerous in the blood Isolation was practically impossible as about two thirds of the 10,752 inhabitants of the town were either sick or carriers, and practically all the special mosquitoes were infected Brigades were formed to aid in fighting the malaria, pools were oiled and twenty-eight houses fumigated The report covers the first sixteen days of the work, 426 sick were found and there were 180 deaths from the disease The scarcity of quinin made it impossible to treat all the sick and there was none for preventive use Efforts were promptly made to enlighten the public as to the epidemic and the necessity for proper treatment In some of the cases the measures that had been previously applied were evidently responsible for some of the peculiar manifestations of the disease, no one thinking of giving quinin, as malaria had not been suspected

The "Epidemics" Gold Medal for Landouzy of Paris—The *medaille d or des epidemies* has been awarded by the French government to Professor Landouzy for his long and ceaseless study of tuberculosis and means to combat it He it was who first established the existence of tuberculosis in very young infants which had been previously denied His conception of typhobacillosis" threw light on a hitherto unsuspected domain of the disease and enlarged the field of acute forms of the disease It was he, also, who revealed the tuberculous nature of pleurisy *a frigore* which upset the traditions as to the necessity of the tubercle for the assumption of tuberculosis He also inaugurated, in 1885, the new movement for social prophylaxis which developed from the old limited conception of "public health" In October, 1915, he took the lead in demanding and organizing measures for the detection and care of tuberculous soldiers -The state in awarding this medal to Landouzy aimed to emphasize in the eyes of the general public the epidemic character of tuberculosis which, French writers say, inaugurates a new era The 1913 statistics for France show a total of 18 552 deaths from all other epidemic diseases, outside of tuberculosis, and of 84,443 deaths from tuberculosis alone During the cholera epidemics, as late as 1884, the death rate from this disease was 4 4 per ten thousand inhabitants, from typhoid in 1913 it was 0 9, from diphtheria 0 63, while from tuberculosis, the death rate was 21 3 10,000

PARIS LETTER

Paris, Jan 4, 1917

The War

SYPHILIS AFTER TWO YEARS OF WAR

At the session preceding the last one, held by the Academie de médecine, Dr Gaucher, clinical professor of cutaneous diseases and syphilis of the Faculte de medecine de Paris, and Dr Bizard made an interesting report on this subject Whereas, before the war, there were, in round numbers, 300 cases of recently contracted syphilis among 3,000 patients treated at the St Louis Hospital clinic (one in ten), during the first sixteen months of the war, 800 cases of syphilis were found among 5,000 patients (one in six), in the eight months following there were 600 syphilitics among 2,300 patients (one in four) Therefore, while during the first sixteen months of the war syphilis increased over 33 per cent (almost 50 per cent), during the following eight months it increased over 50 per cent (almost 67 per cent) Commenting on this remarkable increase, Drs Gaucher and Bizard insist that there were originally many unknown cases of syphilis This fact, they believe, demonstrates the necessity of giving students more thorough instruction on syphilis In fact, students should receive several months of special training in the study of this disease Dr Vaillard, general medical inspector of the military health service, has proposed that the authorities be invited to take the necessary measures to prevent the development of syphilis Following this proposal, the Academie de medecine appointed a commission composed of Drs Gaucher Achard, Vaillard, Pinard and Kirmisson to draft a petition asking the government to enforce this resolution

SMALLPOX VACCINATION BY ARMY PHYSICIANS

M Justin Godart, undersecretary of state of the military health service, has recommended to the regional directors in the service that (1) all soldiers be examined with the view of vaccinating or revaccinating all those who had escaped vaccination, (2) all employees in public or private manufactories operating for national defense be revaccinated with the least possible delay and (3) the medical corps of the army be placed at the disposition of the civil authorities and charged to proceed with the legal revaccination of schoolchildren who have attained the age of 11 years

FOR WAR CRIPPLES

At the suggestion of the Belgian government, cooperating with the French government, a conference of the allies is to be held at Paris, March 6, 1917, to consider the needs of those crippled in the war their reeducation, employment, economic interests, protection, etc The organizers of this movement appeal to all specialists, soliciting cooperation The general secretary may be addressed at "rue de Bocage de Bleville, No 1, Havre" The national office for the wounded at "quai d'Orsay, 97, Paris," will furnish all necessary information to those interested

Are there Carriers of Tetanus Bacilli?

In a report to the Societe de chirurgie de Paris Dr Colombino of Turin answers this question in the affirmative In making a casual bacteriologic examination of infected wounds in patients who had been given an antitetanic serum injection and who had never even shown any symptoms of tetanus, he discovered not only the tetanus spores, as Berard and Lumiere had already observed, but even the bacilli Therefore, Colombino concludes that in the centers in which the wounded are treated, every patient, from the point of view of a tetanus infection, was a menace to his neighbor, and that, consequently, it was unsafe to operate in any manner on a patient whether infected with tetanus or not, without giving him a preventive, antitetanic serum injection This opinion gave rise to an interesting discussion Professor Legueu found Colombino's conclusion somewhat overdrawn He believes that the antitetanic serum injection should be given only under certain conditions and in certain centers where tetanus occurs more frequently or where its occurrence is more to be feared According to Dr Pierre Delbet, clinical professor of surgery at the Faculte de medecine de Paris, the danger to which the carriers of tetanus bacilli subject the other patients is evidently not comparable with that of scarlet fever or diphtheria, but, nevertheless, this danger is real and similar to that which is caused by those who actually have tetanus Dr Broca, assistant professor at the Faculte de medecine de Paris, who, for two years, has operated daily on patients who had not been given preventive injections, has never had a single case of tetanus Dr Routier, on the other hand, for almost one year never performed even a minor operation without giving the patient on the eve, or at least on the morning of the day of operation an antitetanic serum injection He claims never to have had a case of operative tetanus Dr Tuffier, assistant professor at the Faculté de medecine de Paris, does not accept this practice, which he believes applies only when there is a case of tetanus in the service Dr Rochard is of the same opinion Dr Quenu believes that this is a question which needs to be studied further, because at present there are not enough facts to solve it

Oculocardiac Reflex and Subjective Symptoms of Trephined Patients

Dr Paul Sainton, physician at the hospitals of Paris, has drawn the attention of the Academie de medecine to the fact that in trephined patients there is a disturbance of the functional equilibrium which exists normally between the antagonistic, pneumogastric and sympathetic systems Proof of this is the frequency of modifications of the oculocardiac reflexes which denote at times a hyperexcitability of the autonomous system and at others a hyperexcitability of the grand sympathetic system They are comparable to those which have been described as existing in exophthalmic goiter Testing the oculocardiac reflexes should therefore take its place among other procedures which make for the control of the subjective symptoms of the trephined

Formation of a Franco-Russian Medical Committee

This committee has just been formed with a view of attracting to the schools of medicine and pharmacy of France the greatest possible number of Russian students and physicians, to send French students and physicians into Russia on scientific missions, to invite similar Russian missions to France, and to create Russian medical centers in the university cities of France to serve as medicocommercial centers The honorary president of this medicochirurgical committee is Dr Charles Richet, professor at the Faculte de medecine de Paris The acting president is Professor Blanchard and the general secretary is Dr Roubinovitch, physician at the Hospice de Bicetre

Personal

At a recent meeting of the Academie de medecine Prof George Hayem was elected president for 1918

Death of Dr Edward Hirtz

Dr Hirtz, physician at the hospitals of Paris and vice president of the Societe de therapeutique, recently succumbed to a cardiac affection He had distinguished himself by his work on the circulatory system and its therapy

BERLIN LETTER

Berlin, Nov 20, 1916

Tuberculosis and the War

By resorting to proper hygienic and prophylactic measures in the fight against tuberculosis, the authorities have succeeded in reducing the number of cases of tuberculosis occurring in the army in times of peace The most effective measure in this campaign has been the prompt isolation of every suspicious case The incidence of tuberculosis in 1882 was 2 2 per thousand, whereas in 1910 it was only 1 3 per thousand The same condition existed in the Austro Hungarian army Tuberculosis incidence was also greater in the Russian and English armies than in the armies of the central powers Since the beginning of the war it has manifestly been impossible to carry out the measures which resulted in this splendid showing in the German army Persons with a predisposition to tuberculosis naturally could not be excluded from service Furthermore, many of the volunteers withheld the information that they had had pulmonary disease, nor could these cases be detected by the medical examiners, who were compelled to make hurried examinations The need for men made it necessary to accept for enlistment persons with healed or inactive tuberculosis, but many of these have made excellent soldiers, not only withstanding successfully the exacting demands of military service on their constitutional resistance, but even gaining in health and strength The number of new cases of tuberculosis developing in the army is much smaller than was at first expected, notwithstanding the unusually severe conditions under which the soldiers live The clinical picture of these cases does not differ from that of tuberculosis occurring during times of peace As to the prognosis of these cases of war or campaign tuberculosis, as they have been designated, there is some difference of opinion Some observers report having seen severe, rapidly progressing cases, while others claim that many of these patients make a speedy recovery under appropriate hospital treatment

TRAUMA AND TUBERCULOSIS

Much valuable information on the relationship of trauma to tuberculosis may be expected, although, according to present indications, few cases of tuberculosis have developed as the result of trauma in general and lung injuries in particular The lighting up of old or latent cases and the progression of mild cases is not uncommon, however In many instances old cases remained wholly unaffected Moritz investigated cases of gunshot wounds of the chest at various special hospitals, and found a direct etiologic relationship between injury and tuberculosis in nine cases In thirty-six cases the disease was undoubtedly made worse These figures surely are not alarming when one remembers that the cases of lung injury in this war are numerous During the Franco-Prussian war very few cases of pulmonary tuberculosis developed as the result of chest wounds The typhoid prophylactic vaccination, it is believed, also activates pulmonary tuberculosis, although such cases are merely isolated instances Observations made on this subject are very instructive. It is agreed that in a large percentage of cases the original diagnosis of tuberculosis was wrong Fraenkel excluded an active tuberculosis in 60 per cent of the cases, de la Camp in 30 per cent, Blumel of Halle in 80 per cent, and this in the face of the fact that the original diagnosis was made, not after a single examination, but after observations extending sometimes over months and carried on in an institution The reason for these errors in diagnosis, Fraenkel believes, lies in the fact that too great value is placed on relatively insignificant findings A laudable desire to recognize tuberculosis as early as possible has led many physicians to regard indefinite physical findings or an incomplete clinical history as a sufficient basis for a diagnosis of pulmonary tuberculosis Fraenkel says that the diagnosis of pulmonary tuberculosis should be made only when the tubercle bacillus is unquestionably found in the sputum or when a typical roentgenogram is obtained He is convinced that the roentgenogram is never negative in a frank, open case of tuberculosis, or in any case of closed tuberculosis manifesting clinical symptoms All other evidence Fraenkel regards as unsafe, stating that only an overwhelmingly large number of such signs and symptoms should serve as a basis for a positive diagnosis of tuberculosis Goldscheider, de la Camp, Rieder, Scholz and others emphasize the absolute necessity of a Roentgen examination of the chest in arriving at a diagnosis of pulmonary tuberculosis Of course, it is needless to state that a correct interpretation of the roentgenogram must be made Goldscheider says that a shadow in the roentgenogram is not indicative of an active tuberculosis, nor does it justify exemption from military service or referring the individual to a hospital for treatment.

It is well to mention here something that occurred in Switzerland The Swiss military insurance organization was confronted by the problem whether a case of tuberculosis making its appearance during military service was to be regarded as a disease incurred while in service, or as a disease having existed prior to enlistment The majority of physicians today agree with the teaching of Behring and Romer that infection with the tubercle bacillus usually occurs during childhood and that clinical manifestations do not appear until many years afterward in the form of metastasis, and that an exogenous infection of an adult is in general, without significance A commission of Swiss physicians came to the conclusion that pulmonary tuberculosis in these cases was not to be regarded as a disease of military service, but that it had existed previously Not a single case could be found in which it was probable that the infection occurred after the age of 20 Therefore, the military insurance commission felt itself justified in refusing to give an indemnity to these tuberculosis soldiers although, for humanitarian reasons, it was willing to treat these men until recovery ensued Stahelin was strongly opposed to these views He referred to the frequent changes of opinion among physicians as to the exact nature of these cases, and believed that the commission had confused the terms 'infection" and 'illness" If it is true, he said that over 90 per cent of all persons become infected with the tubercle bacillus in their youth, whereas only relatively few manifest any symptoms of pulmonary disease, it is evident that while infection with the tubercle bacillus may have occurred, it was by no means the main etiologic factor of the subsequent illness Grau agreed with Stahelin, and suggested that too firm a belief in the correctness of the teaching of Behring and Romer might prove to be a stumbling block in the effective campaign against tuberculosis

DIAGNOSIS

Little has been added to means of diagnosis Tachau and Mickel have investigated the matter of temperature elevation following exercises and found that the variation in the well and the sick did not consist so much in the absolute increase of the temperature as in the rapidity of its fall In the normal person the temperature falls to normal within half an hour but not in the sick The diagnostic value of this finding is strongly influenced by the fact that other diseases than tuberculosis show such pathologic reactions The opinions as to the diagnostic value of the tuberculin tests are still varied De la Camp's observation is of interest He found that as the result of vaccinations the susceptibility to the tuberculin was altered so that the usual reaction failed to appear Hochhaus found that Pirquet's reaction was negative in the case of many soldiers when one really would have expected a positive reaction

The manysidedness of the clinical picture of pulmonary tuberculosis is laid to the various groupings made of these cases The division made by Turban and Gerhardt is based on the progress of the tuberculous process So far, however as the course of the disease is concerned, the nature of the anatomic process is of greater importance than its spread The Fraenkel-Albrecht classification is made on this basis They recognize the cirrhotic, tubercular and pneumonic processes with combinations of cirrhotic-tubercular and tubercular-pneumonic cases The cirrhotic and tubercular-cirrhotic cases are regarded as benignant because they result in scar formation, the other cases are looked on as being malignant because they are progressive The clinical classification of individual types should be made only after every means of diagnosis has been resorted to, a careful review made of the clinical history, a thorough physical examination, a Roentgen examination, and after noting the course of the temperature and the fluctuations in body weight

MILITARY FITNESS

It is impossible to lay down any rules that can be made to apply to military fitness The individual case must be judged on its own merits, and in the end all such persons affected with tuberculosis must be regarded as fit for military service if they have sufficient physical endurance Open cases of tuberculosis, or such as give evidence of an active process must be exempt from military service On the other hand, old, inactive cirrhotic forms can, under certain conditions, be regarded as fit for all kinds of military service This decision will be justified when the individual concerned has withstood all sorts of service successfully, and when he is sent to the hospital, not because of his tuberculosis, but because of some other illness or as the result of wounds

LONDON LETTER

LONDON, Jan 6, 1917

The War

MEDICAL SPECIMENS FROM THE WAR

In March 1915, the war office constituted a committee to compile a medical history of the war, and the director-general of Army Medical Services became its president, and the secretary of the Medical Research Committee its secretary The two scientific forces were united in one body One of the objects of the committee was to collect from all the military hospitals specimens of interest and permanent value These specimens are of great interest and it was felt that at all costs they must be preserved The collection was begun and the number of specimens received soon mounted up As it was found impossible to carry out the original idea and store the specimens at the Royal Army Medical College, the council of the Royal College of Surgeons decided to place the workrooms and storerooms of the museum at the disposal of the Army Medical Service and to preserve, classify and register all specimens forwarded from military hospitals The war office issued a memorandum telling army surgeons to forward specimens of an interesting and instructive type In 1916 Major T R Elliott was placed in charge of the collection and transmission of these specimens from the pathologic laboratories attached to the base hospitals in France The specimens at the end of 1916 numbered 1,100 They have been carefully stored under the direction of Prof Arthur

Keith, curator of the College of Surgeons Museum In this way a national collection has been built up In order that it may be made of immediate use it has been decided to place the specimens on exhibition and the work of selection has been entrusted to Professor Shattock, pathologic curator of the Royal College of Surgeons When the work of arrangement and correlation is completed, the medical profession, and thereby the people of this country, whether in the army or in civil life, will begin to enjoy the benefits of a singularly clearsighted policy

The Campaign Against Venereal Diseases

The action of the government in providing centers for the free diagnosis and treatment of venereal diseases has been described in previous letters to The Journal The subject continues to receive great attention in the press, and the grave consequences of these diseases are discussed with a freedom which would have seemed impossible a few years ago The National Council for Combating Venereal Diseases has issued a report on its recent activities It points out that on the publication of the Report of the Royal Commission on Venereal Diseases (described in a previous letter), the Council presented a memorial to the Local Government Board urging that financial support should immediately be given by the government to enable treatment centers to be established throughout the country This request being granted steps were then taken to focus public attention on the urgency of the problem by means of a series of conferences in several large towns The most important one was that convened by the lord mayor of London and at it certain fresh legislation was foreshadowed in the home secretary's speech At his suggestion, recommendations were prepared by the national council and submitted to him for consideration These recommendations included (1) the suppression of advertisements by quacks and (2) making the transmission of venereal disease by a person who was aware that he was in an infectious condition a criminal offense One of the earliest activities of the council consisted in undertaking, with the consent and approval of the war office the provision of lectures to troops on the subject of venereal diseases A syllabus was drawn up and a panel of medical men formed who were willing and able to lecture The lecture comprises a description of the diseases and their effects, the urgent need for thorough and early treatment a statement of the dangers of quackery and concealment and an explanation of the modes of infection and of the advantages of continence During the last two years nearly a million men have been addressed on these lines The lectures have been invariably well received, and many letters testifying to their utility have reached the council from officers in high command This work is still in progress, and it has recently been extended, at the desire of the director-general of the army medical service, to include a lecture to each new class of cadets at all the officer cadet schools, so that every new officer may receive the information necessary to enable him to instruct the men under his command The council has also assisted in furthering arrangements for providing facilities for early treatment for soldiers on leave in London, so that there should be no delay in commencing treatment owing to their temporary absence from their depots The rules of all societies approved under the national insurance act include one depriving members of sickness benefit if their incapacity is the result of "*misconduct*" The result is that members suffering from venereal diseases are in many cases unable to obtain this benefit The council came to the conclusion that this rule was likely to exert influence adverse to the campaign against these diseases, by discouraging such members from seeking early and efficient treatment Representations to this effect were accordingly made to the principal societies, pointing out, in addition, that the abolition of the "misconduct rule" as regards venereal diseases would probably be of financial benefit to them in the long run, by relieving their funds from the strain of paying sickness and disablement benefit for the many cases of sickness and disablement arising from neglected venereal disease As a result, resolutions giving effect to the principle have been passed by conferences representing the great majority of insured persons

The national council is preparing to undertake a widespread propaganda Arrangements have been made to hold special training classes for speakers A certain number of men and women will be engaged for whole time services for the national council, and will work under the auspices of the county and town health officers in cordial cooperation with existing social agencies in various parts of the country Arrangements have also been made to train local speakers and secure a panel of physicians who are willing to speak on the medical aspect of the question, and so supplement the teaching of social prevention given by the lay speakers A number of conferences have already been arranged between municipal, medical and hospital authorities in many centers

The most extreme development of the campaign is a proposal submitted to the home secretary by the Hammersmith borough council, which is nothing less than a by-law to enforce chastity It may be necessary to explain that a by-law is a regulation made by a local authority for its own district, with the sanction of the government The council suggests that a man who, knowing the injury he is likely to inflict on himself, his wife and children, and the community generally, consorts with prostitutes deserves to be regarded as no less criminal than the keeper of a disorderly house, and if found in such company or on disorderly premises, he should be made liable to prosecution

The Medical Service in the Somme Battle

The battle of the Somme which lasted five months, is the greatest battle on record The report on it by the commander of the British expeditionary force in France Sir Douglas Haig, has just been published Referring to the medical arrangements, he states that the losses entailed by the constant fighting threw a specially heavy strain on the medical services This was met with the greatest zeal and efficiency The gallantry and devotion with which officers and men of the regimental medical service and field ambulance discharged their duties is shown by the large number of the Royal Army Medical Corps and Medical Corps of the Dominions who have fallen in the field The work of the medical services behind the front has been no less arduous The untiring professional zeal and marked ability of the surgical specialists and consulting surgeons, combined with the skill and devotion of the medical and nursing staffs, both at the casualty clearing stations in the field and the stationary and general hospitals at the base, have been beyond praise Immense help was rendered by the British Red Cross and the Army Medical Corps in their work The health of the troops has been most satisfactory and there was almost a complete absence of wastage due to disease of a preventable nature

On the use of gas the dispatch contains the following paragraph

> The employment by the enemy of gas and of liquid flame as weapons of offense compelled us not only to discover ways to protect our troops from their effects but also to devise means to make use of the same instruments of destruction Great fertility of invention has been shown and very great credit is due to the special personnel employed for the rapidity and success with which these new arms have been developed and perfected and for the very great devotion to duty they have displayed in a difficult and dangerous service The army owes its thanks to the chemists physiologists and physicians of the highest rank who devoted their energies to enabling us to surpass the enemy in the use of a means of warfare which took the civilized world by surprise

Physicians to Charge Higher Fees

Since the war began, the price of everything has greatly increased, and therefore the cost of living is augmented So far most physicians have not increased their charges Newcastle division of the British Medical Association ever, has decided to increase medical fees from 15 to cent, owing to the increased cost of living drugs, e

---

Marriages

Isaac Newton Ratchford M D, Stockt Clarissa Merganten of San Francisco, De

Arthur Francis Grove, M D, to Miss Uline, both of Dell Rapids, S D, December

Francis Dowling, M D, Cincinnati to Phillips of Fort Thomas, Ky, January 19

Del Mar Akin, M D, Stratton Park, Colo Foster of Colorado Springs, December 7

Walter Maurice Lacey, M D, to Miss Marguer both of Cheyenne, Wyo, December 27

Louis Monroe Tomlinson, M D, Harveyville, Kan, to Miss Vinnie S Grissinger, September 28

Julius Napoleon Hill M D, to Miss Kathryn Bayliss both of Murphy, N C, January 4

Julius E Lackner, M D, Chicago, to Miss Florence Simon of Minneapolis, January 25

Deaths

Leopold Frederick William Haas, M D, New York, College of Physicians and Surgeons in the City of New York, 1898, aged 42, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of New York, chief diagnostician of the Bronx Borough Board of Health, attending obstetrician to the Union Hospital, and attending physician to the Home of the Friendless, died in the Presbyterian Hospital, New York, January 18

William Russell Allison, M D, Peoria, Ill , Rush Medical College, 1886, aged 53 a Fellow of the American Medical Association, for several years secretary and once president of the Peoria City Medical Society, for ten years health commissioner of Peoria and once alderman, for five years secretary of the Proctor Hospital Medical Staff, and at the time of his death president, died in his office, January 12, from angina pectoris

Frederick Miller Corwin, M D, Bayonne, N J , New York University, New York, 1881, aged 60, a Fellow of the American Medical Association local surgeon of the Central Railroad of New Jersey, president of the medical board of the Bayonne Hospital and a member of the staff of the East Long Island Hospital, chief medical inspector of the board of education of Bayonne, died at his home, January 16, from heart disease

Frederick W Kienzle, M D, Lynn, Ind , Medical College of Indiana, Indianapolis, 1902, aged 39, formerly a member of the Indiana State Medical Association, died at the home of his mother in Greensfork Ind January 15, from the effects of an incised wound of the throat, self-inflicted, it is believed, with suicidal intent, while despondent on account of ill health

Robert Henry Herkimer, M D, Brooklyn, Long Island College Hospital, Brooklyn, 1892, aged 46, for twelve years chief medical inspector of the health department of Brooklyn formerly a member of the Medical Society of the State of New York, died at his home, January 16, from pneumonia

Charles L Kissling, M D, Milwaukee, Wis , University of Munich Bavaria 1886, aged 57, a Fellow of the American Medical Association a well known practitioner of Milwaukee, and for sixteen years a member of the board of education, died at his home, January 18, from heart disease

Thomas R Cave, M D, Manhattan, Kan , Medical College of Ohio Cincinnati, 1874, aged 64, a Fellow of the American Medical Association, a member of the Golden Belt Medical Society , one of the most prominent practitioners of northeastern Kansas, died at his home, January 22

John Wesley Chambers, M D, Baltimore College of Physicians and Surgeons, Baltimore, 1878, aged 64, a Fellow of the American Medical Association, professor of principles and practice of surgery and clinical surgery in his alma mater died at DuBois, Pa , January 21

William J W Kerr, M D, Corsicana Texas University of Nashville Tenn , 1870, aged 82 formerly a member of the State Medical Association of Texas surgeon in the Confederate service throughout the Civil War, died at his home November 12 from arteriosclerosis

Ward Slosson Gregory, M D, Colorado Springs, Colo , College of Physicians and Surgeons in the City of New York, 1903, aged 37, a Fellow of the American Medical Association, formerly of Norwalk, Conn , died at his home January 14, from tuberculosis

John C Cullen, M D, Anderson, Ind , Medical College of Ohio Cincinnati 1868, aged 79, assistant surgeon of the Sixteenth Indiana Volunteer Infantry during the Civil War, a member of the city council of Anderson in 1884, died at his home, January 17

Andrew Benjamin Knisley, M D, Buffalo, University of the Victoria College, Coburg, Ont , 1885 aged 58, formerly a Fellow of the American Medical Association a member of the Medical Society of the State of New York, died at his home, January 10

James Francis Ferry, M D, Cambridge, Mass , Harvard Medical School 1887, was instantly killed January 21 when the automobile in which he was riding was struck by a Boston and Maine freight train at a grade crossing at Still River station

Irving Drury Chaney, M D, Mount Airy, Md , University of Maryland Baltimore, 1906, aged 35, formerly a Fellow of the American Medical Association, a member of the Medical and Chirurgical Faculty of Maryland, died at Portland Manor, Md , January 18

Clarence Henry Leland, M D, Lowell, Mass , Hahnemann Medical College, Philadelphia, 1873, aged 68, for many years a member of the staff of the Lowell General Hospital, died at his home, January 15, from pneumonia

John Jay Crawford, M D, Coraopolis, Pa , Jefferson Medical College, 1882, Hahnemann Medical College, Chicago, 1884, aged 56, was almost instantly killed by the overturning of his automobile at McClarrens Mills, January 11

Karl Rogers, M D, Cleveland, Tenn , University of Nashville, Tenn , 1907, aged 34, formerly a member of the Tennessee State Medical Association, died in a sanitarium in Cleveland, January 3, from acute nephritis

George Sanson, M D, Ashcroft B C , University of the Victoria College, Coburg, Ont , 1886, aged 54, died at the Royal Victoria Hospital, Victoria, B C, September 4, after an operation for carcinoma

Anthony Keller, M D, Falls City, Neb , Jefferson Medical College 1883, aged 65, formerly a Fellow of the American Medical Association, died at his home, January 10, from cerebral hemorrhage

Roland Sumner Gove, M D, Sanford, Me , Bowdoin Medical School, Brunswick, Me , 1892, aged 46, a member of the Maine Medical Association, died at his home, December 18, from pneumonia

Stephen Augustus Pedrick, M D, Rowley Mass , Tufts College Medical School, Boston, 1895, aged 45, a member of the Massachusetts Medical Society, died at his home, December 28

Charles Wesley Brown, M D, Orland, Me , Medical School of Maine, Brunswick, 1877, New York University, New York, 1888, aged 67, died at his home, January 8, from acute gastritis

Eugene McIntyre Walker, M D, Sylvester, Ga , Medical College of Georgia Augusta, 1914, aged 28, died at the home of his parents in Tifton, Ga , December 30 from typhoid fever

John W Snider, M D, New Castle, Ohio, University of Wooster, Cleveland, 1878, aged 61, a member of the Ohio State Medical Association, died at his home about January 6

Townsend M Luce, St Louis (license Missouri, 1887), aged 78, for more than half a century a practitioner of Missouri, a Confederate veteran, died at his home, January 12

Allen A Barnett, M D, Jerseyville Ill , University of Louisville Ky , 1853, aged 86, formerly a member of the Illinois State Medical Society, died at his home, January 12

William Benjamin Yancey, M D, Atlanta, Ga , Georgia College of Eclectic Medicine and Surgery, Atlanta, 1895, aged 49, died at his home, January 3, from pneumonia

William Blackburn York, Chestnut Bluff, Tenn (license, Tennessee 1889), a practitioner since 1861, aged 76, a Confederate veteran, died at his home, January 3

William A Jones, M D, Colfax, La , Memphis (Tenn) Hospital Medical College 1888, aged 61, was found dead in his office, January 4 from heart disease

Leonard W Estabrook, M D, Springport, Ind , Rush Medical College, 1867, aged 82, a pioneer practitioner of Henry County, died at his home January 8

James N Crabb, M D, Chico, Calif , College of Physicians and Surgeons Keokuk Iowa 1878 aged 65, died at his home, January 4, from heart disease

James H Kimball, M D, Los Angeles, Hahnemann Medical College, Chicago 1880, aged 72, a veteran of the Civil War, died at his home, January 3

Thomas Morrison Burney, M D, Los Angeles, University of Pennsylvania, Philadelphia, 1913, aged 26, died at his home January 6 from tuberculosis

Virgil Andrew Dial, M D, Senath Mo , Vanderbilt University, Nashville, Tenn , 1915, aged 35, died at his home, January 7, from chronic nephritis

James Thomas Rushin, M D, Montgomery, Ala , University of Tennessee, Nashville, 1883, aged 52, died in Montgomery, January 6

William Ralph Fogarty, M D, Brooklyn, Long Island College Hospital 1912, aged 38, died at his home, January 5, from pneumonia

William Skiddy Taylor, M D, Pomona, N Y , Bellevue Hospital Medical College, 1881, died at his home, January 8

Albert T Webster, M D, Carrollton, Ky , Pulte M College, Cincinnati, 1899, aged 58, died at his home,

Association News

THE NEW YORK SESSION

The Local Committee on Arrangements, Headquarters and Meeting Places

The local Committee on Arrangements for the 1917 session to be held in New York City, June 4-8, has been constituted with Dr Wendell C Phillips, chairman, Dr Floyd M Crandall, secretary, and Dr Alexander Lambert, treasurer The following chairmen of subcommittees have been named

CHAIRMEN OF SUBCOMMITTEES

Finance	Dr Alexander Lambert
Registration	Dr Ramon Guiteras
Entertainment	Dr John S Thacher
Hotels	Dr Reginald H Sayre
Sections	Dr Willy Meyer
Scientific Exhibit	Dr Harlow Brooke
Commercial Exhibit	Dr Henry S Stearne
Press and Publicity	Dr George D Stewart
Golf	Dr Charlton Wallace

LOCAL COMMITTEE HEADQUARTERS

This committee has established headquarters at the Academy of Medicine Building, 17 West Forty-Third Street All communications to the local committee or any of its subcommittees should be mailed to that address

GENERAL HEADQUARTERS

The Registration Bureau the Scientific Exhibit and the Commercial Exhibit, together with the information bureau and the American Medical Association postoffice will be housed in the Hotel Astor, which will be General Headquarters

SECTION HEADQUARTERS

The section headquarters and meeting places are announced as follows

Practice of Medicine	Biltmore Supper Room
Surgery, General and Abdominal	Waldorf Astoria Grand Ball Room
Obstetrics Gynecology and Abdominal Surgery	Waldorf Astoria Astor Gallery
Ophthalmology	Astor North Ball Room
Laryngology, Otology and Rhinology	Astor East Ball Room
Diseases of Children	McAlpin Winter Garden
Pharmacology and Therapeutics	Manhattan
Pathology and Physiology	McAlpin Blue Room
Stomatology	Astor Yacht Room
Nervous and Mental Diseases	McAlpin, Roof Garden
Dermatology	Academy of Medicine Du Bois Hall
Preventive Medicine and Public Health	Biltmore Music Room
Genito Urinary Diseases	Waldorf Astoria Green Room
Orthopedic Surgery	Waldorf Astoria Assembly Hall
Gastro Enterology and Proctology	McAlpin Green Room

HOUSE OF DELEGATES

The House of Delegates will meet in the Academy of Medicine Building, convening at 10 o'clock, Monday morning, June 5

SCIENTIFIC ASSEMBLY

General Meeting—The opening meeting of the Scientific Assembly will be held in the Grand Ball Room of the Waldorf-Astoria, convening at 8 o'clock, Tuesday evening, June 5, instead of at 10 a m, as at previous sessions

Section Meetings—The section work will begin at 9 a m Wednesday, June 6 instead of at 2 o clock Tuesday afternoon, as heretofore The sections will hold two meetings, opening at 9 a m and at 2 p m, Wednesday, Thursday and Friday, June 6, 7 and 8, respectively, or until the programs of the several sections are completed

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

GLYCEROPHOSPHATE COMP AMPULS, 1 Cc, SQUIBB

Report of the Council on Pharmacy and Chemistry

"Glycerophosphate Comp Ampuls 1 Cc, Squibb" are claimed to contain, in each, sodium glycerophosphate 0 1 gm, strychnin cacodylate 0 0005 gm, and iron cacodylate 0 01 gm The Council refused recognition to "Glycerophosphate Comp Ampuls, 1 Cc Squibb' because the name did not indicate the potent ingredients and because the administration of a mixture of sodium glycerophosphate, strychnin cacodylate and iron cacodylate is irrational

The preceding statement was submitted to E R Squibb and Sons for consideration The firm replied

> we wish to explain that there has been a small demand for this product no doubt created by other manufacturers We have filled hitherto this demand as far as it came to us using the formula regularly supplied for years by other firms
>
> The name Glycerophosphate Comp to cover a product containing sodium glycerophosphate strychnine cacodylate and iron cacodylate seemed to us to be the best that could be devised under the circumstances It is absolutely impossible to mention all the ingredients in the name as it would give an unwieldy title In passing we might mention that the U S P and N F cover also by the word Compound the potent ingredients in many titles
>
> However the finding of the Council that the formula here in question is irrational must determine our action and we have in consequence decided to eliminate Glycerophosphate Comp Ampuls from our list dropping the article altogether

This cooperation in the work of the Council on Pharmacy and Chemistry is gratifying In passing the Council notes that the foregoing criticism of many Pharmacopeial and National Formulary titles is justified Many Pharmacopeial preparations have names which are not only non descriptive but actually misleading Such are compound powder of glycyrrhiza and compound syrup of figs, both of which owe their activity to senna, and acid camphor mixture and compound mixture of glycyrrhiza, which are *essentially* opium preparations If any of these preparations possess therapeutic value their names should be descriptive, as otherwise they violate a fundamental principle in the nomenclature of medicinal substances a principle for which the Council has contended and which is supported by both the medical and pharmaceutical professions as well as by manufacturers

BRINKLER, "FOOD EXPERT," ACQUITTED

After a trial lasting three weeks, and after twenty hours' deliberation by a jury, George H Brinkler, the self-styled 'food expert," was acquitted on January 16, at Washington D C, of the criminal charge of using the mails to defraud Brinkler was indicted on Aug 7, 1914, and a fraud order was issued against him by the postoffice department, Aug 19 1914 A full account of his methods was published in The Journal, Oct 3, 1914, in this department and the matter has been reprinted in the pamphlet "Medical Mail-Order Frauds'

Witnesses for Brinkler included an exponent of the treatment of disease by the vacuum process, an advocate of mechanotherapeutics, and a 'neuropath," and according to the Washington *Post* the attorney for the defense called "the leading dietetic experts of New York and Philadelphia to prove that the Brinkler theory is sound"

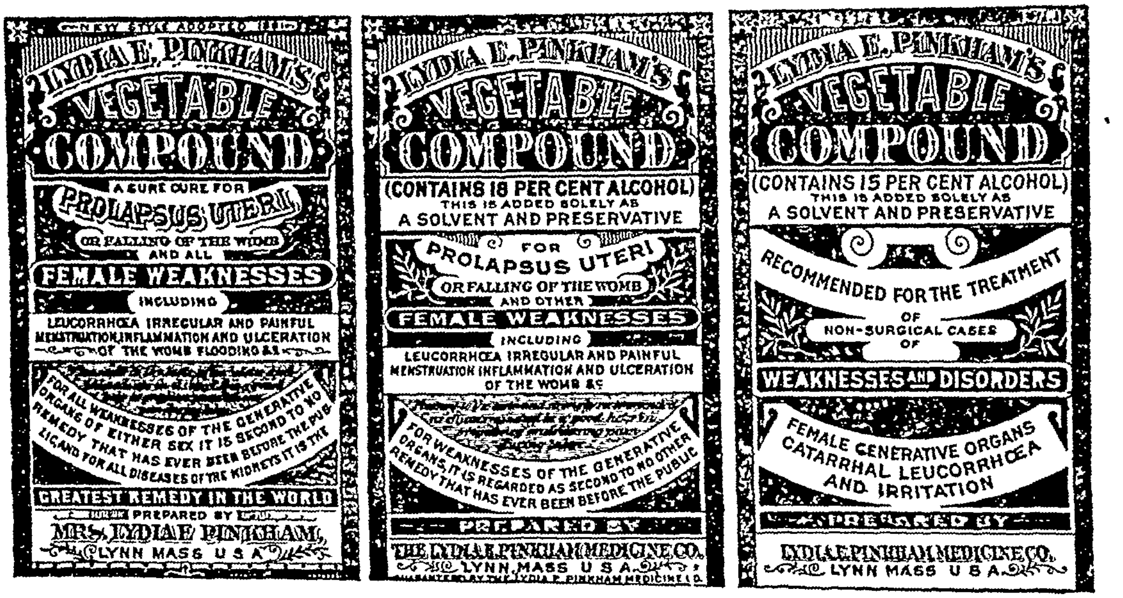
The unfortunate influence of this case on the public may be inferred from the impression sought to be conveyed by the Washington (D C) *Post,* which said

> War to the last ditch is going on at the present time between doctors licensed by state boards to practice according to old conservative rules of materia medica and the new practitioners who are more and more discarding drugs for what they contend is the natural methods of treating ailments, such as dieting, fasting, mental suggestion and the like

There are many practitioners in every city, but it is stated, this was the first big case against any of them

"Court officials agreed that no more difficult proposition ever confronted a jury, and its finding is regarded as a big victory for the advocates of all natural methods of treating diseases"

The "victory," however, can hardly be called a decisive one, since it took the jury twenty hours to return the verdict "not guilty" even after the defendant's best efforts to prove his innocence As a matter of fact the verdict is no evidence of the failure of the prosecution to prove the falsity of the defendant's therapeutic claims, for in order to sustain a conviction in such cases it is necessary for the prosecution to prove to the unanimous satisfaction of the jury not merely that the defendant's claims are false, but to prove also, beyond a reasonable doubt, that the defendant knew of their falsity at the time he made them The verdict is to be accepted therefore, as proving only that the prosecution did not succeed in convincing each one of the twelve jurors, beyond a reasonable doubt, that Brinkler's claims were false *and that Brinkler knew it*, and that with such knowledge he used the mails for the exploitation of such false claims for the purpose of obtaining money thereby



LYDIA E. PINKHAM'S
VEGETABLE
COMPOUND
A SURE CURE FOR
PROLAPSUS UTERI
OR FALLING OF THE WOMB
AND ALL
FEMALE WEAKNESSES
INCLUDING
LEUCORRHŒA IRREGULAR AND PAINFUL MENSTRUATION, INFLAMMATION AND ULCERATION OF THE WOMB FLOODING &c

QUACKS ARE FINED

The State Medical Institute of Omaha Gets a Setback

On Jan 24 1917 W T Upton, E F Andrews and L H Staples pleaded guilty in the federal court at Omaha to conspiracy to use the United States mails for a scheme to defraud Each was sentenced to pay a fine of $350, the fines were paid

This trio was indicted, March 15, 1913, and the men were arrested in November, 1913, when the Chicago *Tribune* was turning the light on the 'men's specialists" quacks of Chicago One of the firms of medical charlatans to which the *Tribune* devoted a good deal of attention was 'Dr Howe & Co' W T Upton was, according to the *Tribune's* report, manager of the Howe concern and also of a string of similar institutions operated under aliases in different parts of the country Here in part is the *Tribune's* report[1] of the arrest of Upton, Andrews and Staples as it appeared in that paper, Nov 9, 1913

"Upton is charged with conspiracy with E F Andrews and L H Staples, both of whom reside in Omaha, to violate the postal laws by advertising the State Medical Institute,' which is the particular name given by the swindlers to their Omaha establishment

'The indictment charges Upton and his two alleged fellow conspirators with representing the institute to be one conducted by skilled specialists in men's diseases, when, 'whereas in truth and in fact, the institute was not a reliable concern, but was conducted solely for the unlawful, fraudulent and felonious purpose of inducing persons to part with their money and property to said conspirators, without giving anything of value in return therefor'

'Upton was arrested in his office by Deputy Marshal Charles Schrimple on a warrant issued by United States Commissioner Lewis F Mason He was taken to the federal building and gave bond before the commissioner The bond was fixed at $2,000 signed by Alphonse Russell and Charles H Touzalin, president of the Touzalin Advertising Agency Assistant District Attorney Peter P Mindak represented the government in the proceedings

The request for Upton's arrest came from District Attorney F S Howell of Omaha, who forwarded a certified copy of the indictment The document recites the method of the alleged conspiracy and contains copies of numerous letters sent out to intended victims by the 'State Medical Institute'

The means of accomplishing the fraud, according to the indictment was to send through the mails letters, circulars and pamphlets and to advertise in the newspapers that the State Medical Institute' 'was an old established and reliable medical institute, conducted by a large staff of skilled specialists of recognized ability in the treatment of diseases of men, and whose experience, reputation and standing was such as to merit confidence'

The indictment continues that it was claimed 'That it could and would cure men in all stages of nervous debility, vital weakness and loss of power That the said letters, circulars, pamphlets and advertisements were so framed as particularly to attract the attention of and excite the fears and prey upon the minds of boys and young men and cause them to believe themselves to be afflicted with diseases of a private, insidious, and dangerous character, which if not at once arrested would result in permanent disability and loss of power, both physical and mental, when in fact they were in a normal and healthy condition and in need of no medical treatment whatever.'"

---

[1] The matter appears in full with a large amount of additional information, in a pamphlet issued by the American Medical Association Men s Specialists, price 10 cents

It thus appears that Upton, Andrews and Staples admit that the 'State Medical Institute," which they operated in Omaha, was conducted solely for the unlawful, fraudulent and felonious purpose of separating the credulous sick from their money 'without giving anything of value in return therefor."

Correspondence

The Differentiation of Spurious from True Anginal Pains by Two Tests

To the Editor:—In some cases of functional heart weakness associated with mild but perturbing chest and arm pain, the functional or neurotic character of the epiphenomena may be differentiated from that more grave in character by the following tests, both of which I have used and found to be of use. The pains in the chest and arms in neurotic angina disappear if the person suffering from them will thrust the little finger firmly into the external auditory meatus, particularly to the left. This no doubt stimulates the aural branch of the pneumogastric nerve, and, by increasing the heart's efficiency thus dissipates the cause of the pain. This is true of pains coming on during exercise.

Again, if the patient will strongly retract the abdomen while suffering from his pain, if the cause is functional heart weakness associated with some hyperesthesia of his nervous system, he will be entirely relieved so long as the abdomen is firmly retracted. This is true more particularly in those who have rather protuberant and relaxed abdomens. Both of these tests will be of service not only in diagnosis but also in calming the fears of those afflicted.

The retracted abdomen method has some therapeutic features as well, since in the compression of the viscera and secondarily of the portal system of veins the right auricle is better filled by the increased venous pressure in the cava and the heart has a little less load to lift. This relief no doubt accounts for the annulling of the pain.

These two methods, it is hoped, will receive further confirmation as to their value by their application, and for this reason I mention them.

Robert L. Pitfield, M.D., Philadelphia.

Sodium Cacodylate in the Treatment of Syphilis

To the Editor:—I was much interested in the study of this subject by Dr. H. N. Cole (The Journal, Dec. 30, 1916, p. 2012).

In 1913 I treated a series of cases of syphilis with sodium cacodylate, but, not getting the desired results, I discontinued its use. In 1915, I became interested again because of the writings of Dr. J. B. Murphy, and applied it in three cases in which the patients had initial lesions.

Case 1.—J. M., man, aged 21, single, shoeworker, came to me with an initial lesion of the penis to the right of the frenum. I began intramuscular injections of sodium cacodylate, 5 grains, in ampuls made by Parke, Davis & Co., every day for ten days. Then I halted for ten days and repeated ten more injections. The sore on the penis entirely disappeared about the ninth day. There was a slight faintly macular eruption of the forearms and abdomen, which soon disappeared. There was no alopecia. When he returned, after the last series of ten injections, there were mucous patches in the throat and some involvement of the left tonsil. I put the patient on mixed treatment, which cleared his throat. He had at end of twenty doses of 5 grains of sodium cacodylate each a positive Wassermann reaction. After mercury and potassium iodid for two months there was a positive Wassermann reaction. To date after three salvarsan treatments intravenously there have been two negatives.

Case 2.—F. S., man, aged 28, married, machinist, had an initial lesion on the penis. Treatment with sixty injections of 5 grains of sodium cacodylate gave results as follows: The initial sore on the penis disappeared in ten injections; there were severe mucous patches of the mouth; the tonsils were badly infected. There was a positive Wassermann reaction. There were syphilids of both arms and shins; marked papular eruption, malaise, and a slight trace of albumin in the urine. I placed the patient on mercurials and at last gave him three salvarsan injections three weeks apart. The result was a negative Wassermann reaction, the skin was clear and the patient felt fine.

Case 3.—D. C., woman, aged 21, single, seamstress, had an initial lesion on the left side of the cervix, and a macular eruption on the face, neck and shoulders, and also, though faint, on the forearms. Thirty injections of sodium cacodylate of 5 grains each were given. The initial lesion disappeared in one week. Mucous patches of the mouth appeared and persisted. The Wassermann reaction was positive. I gave mercurials and potassium iodid for seven months, and salvarsan once. The Wassermann reaction is now negative.

My conclusion after two trials of the use of sodium cacodylate in small or large doses is that it has no effect toward curing the condition; in fact, the throat symptoms were seemingly increased in severity by its use. It has no effect on syphilids of the forearms and shins, and if anything makes them worse.

It improves the appetite, as one would expect. It has some effect on the kidneys as noted in Case 2; it has some effect in healing the initial lesion, as noted in all three of this series; why, I do not know.

I am entirely satisfied that it has no beneficial effect on syphilitics and have discontinued its use entirely in my practice.

I am glad to have read Cole's excellent article, as it shows me that I was correct in my decision not to use it again, as it was worthless.

William G. Ward, M.D., Lynn, Mass.

Compulsory Health Insurance

To the Editor:—In an editorial in The Journal, Jan. 27, 1917, p. 292, appears the statement "The American Association for Labor Legislation prepared a preliminary draft of a model bill on social insurance in which it has properly left blank the section providing for medical services, while asking the assistance of the medical profession to work out this phase of the problem." This statement is not strictly correct. The first two drafts of the model bill for health insurance prepared by the American Association for Labor Legislation left the medical sections in general form. In the supplement to the third and latest draft of the bill appear the sections providing for medical services drafted in accordance with the principles laid down in Dr. Lambert's article, which appeared in The Journal last week. Any readers of The Journal desiring copies of the complete bill can secure them from the American Association for Labor Legislation, 131 East Twenty-Third Street, New York City.

John B. Andrews, New York.
Secretary, American Association for Labor Legislation.

The Response of the Pyloric Mechanism

To the Editor:—In an editorial on W. E. Morse's experiments on the emptying of the stomach (The Journal, Jan. 13, 1917, p. 124), it is stated that the rapidity of discharge diminishes with the increase of acidity, and that this is "so contrary to the accepted version of what occurs" (here stands a reference to my 'Mechanical Factors of Digestion"), that the problem is again presented for solution. In the volume referred to I have given evidence that various factors aside from acidity of the gastric contents affect the rate of gastric discharge. But I have pointed out that when these factors are made uniform and the acidity is varied, the rate progressively diminishes with increase of acidity (see p 120) The fact was established by Hedblom and myself over seven years ago Quite naturally a variation of consistency from that of the food we employed, such as the use of water, for instance, in Morse's experiments, results in the effect of acidity being seen at different concentrations from those we observed—a condition which Morse clearly perceived and explained in his paper That the rapidity of discharge of water diminishes with increase of acidity and that the rapidity of discharge of potato diminishes with increase of acidity are not such contradictory statements as your editorial implies

Blastomycosis of the Tongue

To the Editor —The article on this subject by Dr Gordon B New (The Journal, Jan 20, 1917, p 186) to me is unconvincing

Both Figure 3 and Figure 4 are not characteristic of the microscopic features of any known form of blastomycosis They have more resemblance to lymphosarcoma or the Hodgkin group of tumors than to blastomycosis Furthermore, I am not convinced that the mere presence of blastomycetes (if these are blastomycetes) can excite a lymphoid hyperplasia

Figure 5, pure culture blastomycetes, to my mind is a picture of a culture of common yeast fungi In cultures of blastomycetes, one always finds mycelium

The fact that the lesion healed under potassium iodid and radium is by no means proof that it is blastomycosis

Perhaps Dr New has better proof than he has published in this article If so, it should be published, as those who are familiar with blastomycosis, in my opinion, will refuse to accept his conclusions

Richard S Weiss M D, St Louis

SIMPLIFIED TECHNIC FOR LEUKOCYTE COUNT

To the Editor —In The Journal Feb 9, 1910 p 662 is a brief extract from *Hospitalstidende* Dec 1, 1909 p 1553 under the title Improved Technic for the Blood Count It states that the blood is transferred to a vial containing a bead and a fluid to dilute the blood, dissolve the red corpuscles and fix the whites Nothing is mentioned about the amount of the blood and *amount* of fluid in the vial or test tube Kindly give me an exact extract of the original article covering the points in question

V W Pleth M D Sonora, Calif

Answer —One large drop of blood (25 c mm) is drawn into a pipet and deposited in a vial or test tube already containing a small glass ball or bead and 19 drops of a fluid which dissolves the reds, fixes the whites and prevents shriveling as they dry The test tube plugged with a rubber stopper can then be set aside until it is convenient to make the leukocyte count As many test tubes can be used as desired, and the count can be made several times from each test tube, the average from a number of counts insuring greater accuracy A capillary pipet marked for 25 c mm and for 10 c mm is used for the blood, and a larger pipet for the mixing fluid, marked off for the exact amount required, namely, nineteen times 25 c mm 19 × 25 = 475 c mm A stand to hold a portable set of the test tubes is also convenient, as a number can be accumulated from the same or different cases and kept for a few days until a convenient moment arrives for the microscopic work, or the set can be sent to a laboratory The mixing fluid found best adapted for the purpose consists of 45 c c of decinormal hydrochloric acid, 45 c c of a 0 9 per cent solution of sodium chlorid and 10 c c liquor formaldehydi The count is made by taking up 10 c mm of the fluid in the test tube and spreading it over a circle, exactly 2 cm in diameter, marked on an object glass The specimen is then stained with a mixture of equal parts of a 1 per cent aqueous solution of methylene blue and of a 0 2 per cent solution of sodium hydroxid The stain is left in contact for one minute and then rinsed off, leaving the object glass in water for from two to five minutes, then embedding in cedar oil The number of leukocytes in 100 microscopic fields, multiplied by 50, gives the number of leukocytes per cubic millimeter This formula is based on the ratio between the diameter of the microscopic field (0 4 mm) and the area of the circle (100 sq mm) The article is illustrated, and directions are given for facilitating the count by means of dividing off the circle on the object glass into quarters, etc The blood specimens can be used later for the differential count Ellermann and Erlandsen worked with 100 microscopic fields for each specimen, and state that with a little practice the whole procedure takes amazingly little time With 200 microscopic fields, they found that the error averaged only 3 4 per cent

TREATMENT OF PSORIASIS

To the Editor —Has there been anything new and effective developed in the treatment of psoriasis? Can you advise me if the vaccine treatment is producing any favorable results?

F H Moore M D Herkimer, N Y

Answer —Various new methods have been proposed and tried more or less in the last few years, but none of them has proved of great value In general, chrysarobin ointment still remains the most effective remedy for cleaning up psoriasis The custom today is to use it in rather dilute strengths—from 2 to 5 per cent chrysarobin in some ointment base The lesions can often be cleaned up with Roentgen rays but the method is not to be recommended unless used with great caution As a rule the eruption recurs after Roentgen-ray treatment, as after all other methods of treatment Another recent method of treatment is exposure to highly actinic rays of light Sometimes ordinary sunburning will clear up psoriasis and exposure to ultraviolet light may do the same thing, but as a rule this method of treatment is disappointing Autoserotherapy is the latest method suggested but it has not yet been proved of value The same can be said of the treatment of psoriasis with vaccines

VIBERT'S SOLUTION FOR STAINING BLOOD CELLS

To the Editor —Please give me the composition of Vibert's solution for the preservation of blood cells in their removal from blood stains Mention is made of it in the *India Journal of Medical Research* (3, 214) in an article by W D Sutherland on Examination of Blood Stains in Medico Legal Cases

Heber C Jamieson M D Edmonton South Canada

Answer —Francis S Smith ('Forensic Examination of Blood Stains in the Tropics" *Bristol Med-Chir Jour* July, 1916 p 84) gives the composition of Vibert's solution as a 0 5 per cent mercuric chlorid solution in 2 per cent sodium chlorid He says

> Microscopic Examination —A small quantity of scrapings from the stained area in the case of earth, knives and bamboos or a portion of the fabric in the case of clothes is taken and allowed to soak in a drop of Vibert's solution (0 5 per cent HgCl solution in 2 per cent NaCl) or in a drop of glycerin solution (one part in seven of water) It is then covered with a cover glass and after standing for half an hour is tested and examined under low power high power and oil immersion lenses Mammalian blood cells and the oval granular nuclei of nonmammalian corpuscles can be detected

---

Typhoid Immunization —The October number of the *Bulletin of the New York State Department of Health* is the 'Typhoid Number" It is said that in view of the excellent results obtained from prophylactic immunization, it would be wise to immunize all the remaining members of a family in which a case of typhoid fever has occurred A study of typhoid fever in certain sections of the state reveals that about one third of the patients received the infection by contact with an acute case, either in the same family or in the home of a neighbor In view of this it would seem wise, except in well regulated hospitals or homes where there is an adequate water carriage system for the removal of excreta to isolate the patient as rigidly as for a case of scarlet fever

TEACHING INTERNAL MEDICINE

Each Student a Teacher

STEWART R ROBERTS, S M M D
Professor of Medicine and Clinical Medicine Emory University
(Atlanta Medical College)
Atlanta Ga

Much is written of curriculums and hours allotted for different courses, and but little on methods of teaching Even medical teachers and whole faculties seem to lack for words when it comes to didactic methods In the selection of teachers and faculties much consideration is given to the training and research ability of a man, and but little to his real teaching ability, or his personal power to impart his training and knowledge The old lecture is largely a thing of the past, yet certainly students need in their senior year some didactic touch in internal medicine apart from the bedside The following twofold round table idea has been gradually developed in the Atlanta Medical College, and I have used it for two years with increasing evidence of its value With small classes and in other departments the plan will probably be equally practical

First in the examination of patients in the hospital a student is assigned to a patient to take the history, make the examination, do the laboratory work, and hand in a detailed report of his findings Questions arise in the examination or in the laboratory work and the student in charge of the case is assigned work on which he reports at the next meeting of the class For example, one patient with pellagra has a dicrotic pulse and the student who is studying the case is assigned, in addition to the ordinary study of the case, the dicrotic pulse—to explain its origin, its meaning, in what diseases it occurs and to see if he can determine by palpation the difference between the dicrotic pulse, the pulsus alternans and the bigeminal pulse At the next meeting of the class or of the section, he summarizes his studies, or writes out the distinctions, and makes diagrammatic tracings of each pulse form

Another student in examining a patient found a marked pyorrhea stained a pus smear, and found the *Amoeba buccalis* He was assigned the subject of "amebas in man," and he is now preparing a paper on that subject, and will summarize his findings on the board This summary takes from two to five minutes to notice or read but the student has looked up the literature, and has a fair idea of it when he reports

Another student studying a case of lobar pneumonia was requested to give his section the next day in the ward a differential diagnosis between lobar and bronchopneumonia, and the following day he gave a differential diagnosis between acute bronchitis and bronchopneumonia One student may call another in consultation on his case The idea is to let the student studying pneumonia in the ward know not only his patient and the disease, but also teach, as far as he can, what he has learned to his fellows in the section His teacher simply outlines, guides and corrects The student is human, he realizes his powers, and his ability awakens his interest and energy

Secondly, this teaching plan includes a systematic method of study of the literature, the preparation of papers, and an individual talk by the students to the class as a whole In addition to the bedside work at the Grady Hospital, the seniors receive thirty hours from Professor Strickler on infectious diseases, and thirty hours from the writer on diseases of the heart, arteries, blood and kidneys, or one hour per week throughout the year The present class numbers sixty-six men, and at the beginning of the year a subject is given to each man A list of the men and subjects is posted in the library The subjects follow, and it will be found that these cover the headings usually included in teaching diseases of the heart, arteries, blood and kidneys Assignments are so made that at the close of the year, taken together, they form a systematic course, and subjects are presented to the class in the following order

Conduction system
Position of the heart
Endocarditis
Myocarditis
Pericarditis
Senile heart
Heart poisons
Signs of heart failure
Passive congestion
Hypertrophy and dilatation
Congenital heart disease
Arteriosclerosis
Tachycardia and bradycardia
Blood pressure technic
High pressure
Aortitis
Embolism and thrombosis
Angina pectoris
Pulse character
Pathology of aneurysm
Symptoms and treatment of aneurysm
Sinus arrhythmia
Premature contractions
Auricular fibrillation
Auricular flutter
Paroxysmal tachycardia
Pulsus alternans
Heart block and Adams Stokes disease
Heart in pneumonia
Heart in fevers
Cardiac asthma
Circulation in cirrhosis of the liver
Heart strain
Edema
Treatment of edema
Digitalis
Opium
Strophanthus
Nitrites
Nauheim baths
Nervous symptoms in heart disease
Secondary anemia
Pernicious anemia
Banti s disease
Leukemia
Movable kidney
Congestion of the kidney
Renal calculi
Casts
Albumin
Sugar
Nonprotein nitrogen
Ammonia
Urea
Uric acid
Diabetes pathology
Acidosis
Treatment of diabetes
Pyelitis
Pyonephrosis
Functional tests
Acute nephritis
Tubular nephritis
Chronic vascular nephritis
Uremia
Influence of focal infection on heart and kidneys

The student is directed to write a paper on the subject assigned him and references in books and current literature are given him outside the class and occasionally suggestions for subheads and outlines of theme He is required to add a bibliography at the close, giving references and sources of information When the time has come to discuss, for example premature contractions, the student assigned that subject hands in his paper walks to the front and addresses the class, summarizing his studies and paper He has been told that he is the authority in the class for the year on that subject, in other words, he has a personal teaching responsibility to the class for his subject and frequently he is so full of it that the difficulty consists in holding him down to the ten twenty or thirty minutes which the importance of his subject justifies There is not time enough to exhaust any subject, and the attempt is made to hold him strictly to the mountain peaks of importance in his talk Frequently I throw out a question, or lead him back when he wanders afield or into too much detail At other times and with less important subjects, he is permitted to summarize in the form of 'conclusions" on the blackboard In his paper, however, he must go thoroughly into the subject discuss details and pathology, and fully cover the disease At the close of his talk or summary, his fellow students may ask him questions and remind him, always courteously of omissions Often a student requests his paper back that he may rewrite it because the discussion has brought out points omitted in the first draft Each paper is corrected, and often handed back for revision or because the bibliography has been omitted, but rarely for failure to cover the subject thoroughly

Questions arise which demand ready assistance from the authority in the class on that particular subject For example, the student discussing the senile heart edges too far into the subject of myocarditis, and the student authority on myocarditis comes to his aid A misstatement on the part of the student-lecturer brings an instant shaking of heads The attention is perfect The hour is never long enough for students, subjects or teacher After the papers are corrected, they are filed in the library and form the textbook for the class for the year One student takes notes in shorthand typewrites them, and sells the lot to each member of the class The examination is based on these papers If time and opportunity allow, the student is referred to hospital cases illustrating his subject, so that he gains material for his paper from books, current literature and the bedside After a student has finished a subject, frequently a second subject is assigned to him

It is true that but little time can be given to each subject, and the objection can rightfully be made that while each one is covered thoroughly on paper, it is covered only superficially before the class, but the paper is open in the library to the study and criticism of each man The added individual interest and pride on the part of the student transforms what is called teaching into personal association Students and teacher are together teachers and student, and their teacher is simply an older student, or in the beautiful word of the Japanese for teacher, *sensi*, one born before, or one who has experience

ADVANTAGES OF THE METHOD

1 It teaches the student to consult many books and current literature, and to find illustrations at the bedside

2 It teaches him to write a paper, and prepares him for activity in the hospital and the medical society

3 It teaches him to talk before his fellows, and to think on his feet

4 It teaches him the use of the library and the importance of current literature

5 It teaches him to summarize, to give authority for his statements, and to base his conclusions on facts and not on opinions

6 It arouses his interest, compels his attention, impresses his memory, and stimulates his reason

Oklahoma July Report

Dr Ralph V Smith, secretary of the Oklahoma State Board of Medical Examiners reports the oral and written examination held at Oklahoma City, July 11-12, 1916 The total number of subjects examined in was 11, total number of questions asked, 100, percentage required to pass, 70 The total number of candidates examined was 32 of whom 29 passed including 1 osteopath, 2 failed, and 1 was refused registration on account of immoral character Fifteen candidates were licensed through reciprocity, including 2 osteopaths Five candidates were granted reregistration licenses including one nongraduate and one whose graduation could not be verified The following colleges were represented

Book Notices

Bacteriology General Pathological and Intestinal By Arthur Isaac Kendall B S, Ph D Dr P H Professor of Bacteriology in the Northwestern University Medical School, Chicago Cloth Price, $4 50 net Pp 651, with 107 Illustrations Philadelphia Lea & Febiger, 1916

This book covers ground that is dealt with in other texts on bacteriology, but as it reflects the experience and personal views of the author it will prove a valuable addition to the library of the student of medicine Dr Kendall designates his book as covering general, pathologic and intestinal bacteriology, and while it is not clear why intestinal bacteriology should be so sharply differentiated from general and pathologic bacteriology as the title seems to imply, the summary of Dr Kendall's own work on the intestinal flora will be generally welcomed, a little overemphasis is not likely to do harm The text as a whole is clear and accurate and brought well up to date The statement on page 488, with regard to botulism, that hams similar meats and meat products alone cause the disease,' is not correct in itself, and is in some degree contradicted by a statement on page 486 In this section no mention is made of the important work done on botulism in California A few misprints are noticed here and there, as on pages 35, 130 358 and 607, but they are not for the most part very important The use of "pleiomorphic for "pleomorphic" seems to be more than a mere misprint since it occurs throughout the book The style is fairly clear and straightforward, although involved sentences like the following are somewhat too frequent "Papasotirin and Prescott have isolated bacteria indistinguishable from *Bacillus coli* by cultural methods from hay and dried grains and the organism is very frequently present in flour, consequently the identification of it in milk does not furnish conclusive evidence of contamination either from human or bovine sources"

The New Method in Diabetes The Practical Treatment of Diabetes as Conducted at the Battle Creek Sanitarium, Adapted to Home Use Based Upon the Treatment of More than Eleven Hundred Cases By J H Kellogg M D LL D Chief Medical Director of the Battle Creek Sanitarium Leather Price $2 50 net Pp 177 Battle Creek Good Health Publishing Company 1917

In this book, Dr Kellogg discusses the Allen treatment of diabetes with particular reference to the needs of the trained nurse and the intelligent patient, as well as of the physician There is, of course, no question that the diabetic patient needs safe instruction This is especially true when he is undergoing at home such a treatment as that outlined by Allen The author considers first the fundamental questions of body physiology and pathologic chemistry in this disease Under 'New Method in Diabetes," he briefly points out the restrictions to which the diabetic must be prepared to limit himself Under "Modern Methods of Examination" the author then takes up the diagnostic procedures involved in the determination of the severity of the patient's condition He introduces here a chart known as the 'Metabolism Graphic," a specimen of which is included with the book The use of this chart permits the physician to have before him in graphic outline an analysis of the patient s condition This analysis includes an estimation of such factors as the urinary sugar the percentage of increase of blood sugar, the carbohydrate balance, the degree of acidosis, the energy balance the water balance the respiratory quotient the food intake the patient s weight etc and each of these points is discussed separately in the chapter mentioned The discussion of feeding of diabetics includes a description of the inauguration of the fast the method of feeding with estimation of calories and food values and also a series of standard bills of fare The author then takes up general health rules for the diabetic These rules would—by the way—also be beneficial to those members of the family not afflicted with the disease Other chapters concern complications of the disease, the care of a case in the home, directions for testing the urine, etc The remainder of the book, about fifty pages, is devoted to recipes for the preparation of the special foods required by the diabetic

Social Medicine, Medical Economics and Miscellany

A Rural School Survey

Public Health Service Bulletin 77 describes a survey of the rural schools of Porter County, Ind , conducted by three officers of the United States Public Health Service The survey covered not only the physical and mental condition of the children, but also the schoolhouses, grounds, water supplies, toilet accommodations, etc Porter County has an area of 415 square miles and a population of 21,250, 85 5 per cent being native born The school population is 3,933 and the total school enrolment 3,103 The average number of children in a family was 4 8, or 2 44 boys and 2 36 girls Seventy-five rural schoolbuildings were surveyed, and medical examinations made of all the children Of the buildings, thirty-three were frame, two cement and forty were brick, and sixty-seven were one story In the seventy-five schoolbuildings there were 114 class rooms Four rural schools obtain their water supply from town water systems, two are supplied by wells of from 125 to 130 feet deep, and thirteen or 17 3 per cent, are without wells The remainder, nearly 75 per cent, are supplied from shallow driven wells Sanitary drinking fountains were found in seven schools, but of these two were out of order and one was not in use In all other cases, the children drink at the well For toilet accommodations, there were four inside closets and seventy-one outside privies, none of which ranked higher than 50 in a possible 100 Sinks for washing were provided in three schools, while in fifty-six schools common wash basins were found Paper towels were provided in eight schools, and individual towels provided by the parents were in use in three schools Common towels were used in forty-one The report contains summaries of findings on floor material, school desks, window shades, blackboards, illumination, ventilation and heating, temperature regulation, etc , all most interesting and of ultimate bearing on health conditions, but too lengthy for recital

Part II of the report covers the physical condition of rural schoolchildren As stated above, there is a total of 3 103 rural schoolchildren in Porter County The average daily attendance in the rural school for the school years of 1914-1915 was 2,512 The physical survey included 2,488 schoolchildren, 1,253 boys and 1,235 girls The age limit was from 6 to 16 Interesting data regarding height, weight, racial differences, vital capacity, chest expansion, cephalic index, pulse, respiration and nutrition were collected, but they are not capable of being generalized Regarding defects and diseases, however, 2,228 disease conditions were found among the boys and 1,985 among the girls Among 1,253 boys, there were 392 defects of hearing and 592 defects of vision, 749 boys had defective teeth, 166 had adenoids, 89 had enlarged tonsils and 25 had spinal curvature Of the 1,235 girls, 348 had defects of hearing, 550 defective vision, 637 defective teeth, 122 had adenoids and 106 had enlarged tonsils Defects of the heart were rare, only seven boys and three girls having any serious circulatory disturbance Only two cases of tuberculosis were found, both of them being in girls The large number of dental defects is easily accounted for by the fact that 18 3 per cent of the boys and 10 5 per cent of the girls had never used a toothbrush, 67 8 per cent of the boys and 48 6 per cent of the girls had used a toothbrush only occasionally, while with only 13 9 per cent of the boys and 40 9 per cent of the girls was the use of the toothbrush a daily habit A study of the mental conditions of 1,087 girls and 1,098 boys made by the Binet-Simon tests show 193 children who were retarded and 21 who were especially retarded, making 214, or 9 3 per cent, of the children whose mental condition needed special attention and instruction Mental defectiveness was found almost equally in the two sexes A larger proportion of physical defects was found among the retarded children than among children whose mentality was normal Twenty-one children, seven girls and fourteen boys, were feebleminded to a degree which rendered it improbable that they would ever develop beyond the mental status of a child Three epileptics and two morally irresponsible children were found

From the facts collected, the surgeons in charge of the survey concluded that there is an undue number of one room rural schools in the county, and an undue number of old buildings which have passed the limit of usefulness The large number of children presenting physical defects is an evidence of the need of medical supervision, both for the sake of the child and for the protection of the community, while the number of mentally defective children found emphasizes the necessity of a mental classification of the children in order to separate those in need of institutional or individual treatment A number of recommendations are made, among them being the consolidation of rural schools wherever possible, the remodeling of many others along sanitary lines, greater attention to daylight illumination, better provisions for sanitary toilet accommodations and for the protection of school water supplies, better heating and ventilating provisions the combining of the duties of medical inspection of schools with those of the local health officer, and the securing of a full time health officer for the county

Women in the Munition Factories

An investigation of working conditions and the home surroundings of women workers in one of the munition factories in New England was made by the Russell Sage Foundation under the supervision of Prof Amy Hewes, of the Department of Economics Mount Holyoke College, and former secretary of the Massachusetts Minimum Wage Commission In the *Survey* (Jan 6, 1917), Professor Hewes gives some of the findings of the investigation Among 164 women 146 of whom lived at home with their families, and eighteen in boarding houses or furnished rooms, the majority were born in the United States Ten were from foreign countries All were regarded as alert, ambitious and representative American working women The majority were under the age of 24, and 80 per cent were unmarried In this munition town, which is at the center of the munitions business, Professor Hewes says three serious issues have arisen with reference to the women along with the high rate of wages Women have been induced to work long hours at night, they work with or near explosives which sometimes mean accident, industrial poisoning or other illness, the high price of labor has been paralleled by the exceptionally high cost of living, which includes high rents, with almost inevitable overcrowding or other unfavorable living conditions Night work is unpopular with most of the women, on account of the difficulty of getting sufficient sleep in the daytime, unsuitable time for recreation and, in the case of married women, neglect of their houses and children, with consequent physical deterioration of the latter On account of the tension, high speed and conditions surrounding the work, much the same conditions are developing here as among the munition workers in England In September, 1915, an English committee, appointed under the ministry of munitions 'to consider and advise on questions of industrial fatigue, hours of labor and other matters affecting the physical health and physical efficiency of workers in munition factories and workshops, went on record as opposing night work as being uneconomical because of higher wages and lower output, on account of the difficulty of arranging adequate lighting, because of the difficulty of securing sufficient sleep, and because of unwonted meal hours with consequent derangement of digestion For profit alone, it is said, the manufacturers in the United States are producing munitions with feverish haste by methods which have been declared wasteful by the English investigators The tendency is to lengthen the hours and to reduce wages, notwithstanding that the cost of necessities and rents is now out of proportion to even the high wages paid, as shown by a comparison with the wages in other New England industries in normal times Connecticut, the state in question, it is said, has no law preventing all night work by women They are allowed to work until 10 p m, and the factories get around the law by having them rest from 10 to 12 and then go to work again, the law saying nothing specifically about when they may go to work in the morning Among the suggestions for bettering conditions among women workers, Professor Hewes offers the following prohibition of night work, reduction of working hours from ten to eight, and for only six days in the week, a minimum time of one hour for luncheon (15 minutes being now allowed in some factories) education in accident prevention, with a compensation law providing higher compensation and a shorter waiting period, provision for clinical treatment of sufferers from industrial diseases and compensation as in the case of industrial accidents

Too Many Medical Papers

The scarcity of paper and its increased cost seem to be universal The *Policlinico* of Rome, in commenting on the fact that many medical journals have suspended and that others have been reduced in size, regards the condition as not an unmixed evil "The most tangible result," it says is that the amount of material published is sensibly reduced This is not a serious evil, as too much has been and is still being published It is not a bad thing for literary production to be restrained, condensed, reducing particulars to inclusive wholes It is certain that the larger proportion of medical journals contain too much that is trite, deplorably banal They accumulate too many useless data which might be suppressed to great advantage Many articles have not the slightest reason for existing and they merely cumber medical literature Graphomaniacs [this is not a bad word, it would not be out of place if applied to some medical men in this country] abound among physicians, some are graphomaniacs from temperament, others from policy" Presumably the *Policlinico* means here that it is an elegant and ethical form of self-advertising Farther on "Regardless of the superficiality of certain arguments they dilate on them and dilute their personal observations with a flood of already known facts and opinions Their writings contain very little that is new, and what is new and interesting is padded out and strung along *ad nauseam* The same work appears first in some first class journal and then, under other titles and with slight changes, it appears in minor periodicals and it fills up space and wastes time in medical bibliography We refrain from further descriptions for fear that they might have a too personal tinge We all know that the incontinence [a good word in the original—it is *incontinenza*] of these authors might be checked and corrected" The *Policlinico* then begs writers to spare the editorial staff the waste of time and energy required to pass judgment on unworthy articles 'not to mention the disagreeable task of rejecting such manuscripts and the load of responsibility it places on the editorial staff The writer concludes with this advice, which we respectfully pass on Abstain from recording the commonplace, and let those who have something really interesting to report suppress useless details long historical introductions, and rehashing of textbooks'

Health Administration—The results of the health survey of St Paul, made by Surg George B Young U S P H S, appear in *Public Health Reports* January 12 This study is similar to those made by the service in other cities Dr Young finds that the situation from a legal standpoint is uncertain Old ordinances contradict each other or are not in accordance with the charter, while some public health activities are untouched Some of the provisions of the charter are contradictory and some of the ordinances have been automatically repealed as being in conflict with the charter The general sanitary status of the city was found to be good, the fundamental elements of a healthful community—a healthful site, a good water supply, a prosperous population derived from strong stock and unweakened as yet by generally congested housing and insanitary industrial conditions—are all present The death rate for the city per thousand of population was never higher during any year from 1906 to and including 1915 than 11 4, and more than half of those years it has been below 11

Using Mails for Fraudulent Scheme of Alleged Divine Healing

(United States v Schlatter et al (U S) 235 Fed R 381)

The United States District Court in California, overrules a demurrer to an indictment charging the defendants with the crime of conspiracy to violate Section 215 of the federal penal code Briefly the scheme devised and contrived by the defendants, as alleged in the indictment, was that they would induce any and all persons whom they could induce to communicate with them to believe that they could and would cure almost all manner of known diseases by and through the medium of divine power Specifically, for instance, it was alleged that the defendants conspired to represent to credulous ones, with whom they could get into communication, that they could and would bless a handkerchief, and that if a person afflicted would apply such handkerchief to the afflicted portion of his or her body, he or she would thereby become cured This, of course, was to be quid pro quo or consideration, not necessarily certain or definite in amount but such a sum as the one seeking a cure felt justified in contributing Substantially, the charge against the defendants was that, with the knowledge that they could accomplish no cures and with the deliberate intention to defraud, they conspired together to contrive and consummate a scheme wherein and whereby through the medium of alleged divine healing, they would obtain and convert to their own enrichment the money and property of such persons as might be sufficiently gullible as to be attracted by their specious and alluring promises of relief all the while intending that such persons should receive no return for their money and property, save that comprehended in a dismal and costly experience As a part and parcel of the scheme, and in furtherance thereof it was alleged that they intended to and actually did, make use of the mails of the United States The court says that in its judgment, this stated a complete offense and, if the proofs be made in adequate support of the allegations in the indictment there was no doubt but that the defendants should suffer punishment therefor The point made in the brief of the demurring defendant's counsel apparently was that the defendant was and professed to be nothing more than a divine healer, and that divine healing has been practiced since the time of Christ and in some form or other is practiced now by many reputable and widely recognized individuals and cults That mental healing or even divine healing per se or in and of itself is under the laws of the land, as lawful as healing with drugs or by massage or other mediums is true But it is not true, never has been true, and never will be true that fraud can be glossed over or rendered reputable in the eyes of the community merely because it is associated with, or a feature of, some undertaking otherwise lawful in its nature and innocuous in its effect In other words, the mere fact that a fraudulent scheme centers about divine or other healing does not in any wise or sense serve to take it out of the domain of a fraudulent scheme, and if, in furtherance of such a scheme conceived in fraud, the mails of the United States are made use of without doubt by whomsoever conceived or consummated, the perpetrators of such schemes should receive prompt and merited condemnation and punishment It was therefore no answer to the crime charged in this indictment to assert that the defendants were engaged in the praiseworthy vocation of divine healing That in no wise answered the charge that with a knowledge that they were rendering no service at all to their "patients, and with the deliberate intention on their part to defraud their patients, they were using the mails of the United States in aid of their scheme to separate their patients from their money The whole question without doubt revolved around the proposition as to the good faith of the defendants If they were acting in good faith in their promise to bring the bloom of health back to the cheek of him who might make use of one of their blessed handkerchiefs then, no matter how visionary their view may have been, no matter how ill founded their conclusions may have been, no matter how much sheer incompetence in the exercise of judgment may have been their portion, they were not liable to prosecution as for the perpetration of a fraud on those who became their dupes The simple query in the case was Were they actuated by good faith? The indictment said they were not, but were moved by an intent to defraud In the face of that they could not claim that no crime was charged against them

Admissible Evidence of Criminal Abortion

(State vs Newell (Minn) 159 N W R 829)

The Supreme Court of Minnesota, in affirming a conviction of the defendant of manslaughter in the first degree in the commission of an abortion on a young married woman, says that the woman went to the home of the defendant with the avowed purpose, if the testimony of her husband and her mother was credited, of procuring an abortion There was evidence that there was an abortion The evidence that the defendant caused it was largely circumstantial, but it rather clearly pointed to her guilt The question was for the jury, and the evidence very amply supported the finding of guilty Declarations made by the woman while under treatment, and before the abortion, as to the treatment given by the defendant, were competent evidence Nor was there error in receiving on behalf of the state the testimony of another woman who stated that shortly before the date of the crime charged she went to the defendant for the purpose of having an abortion performed and that the defendant consented to perform it, though it was not performed It was urged that the admission of this evidence, and other of like character was error The authorities approve such testimony It is received for the purpose of showing a guilty or criminal intent in doing the act alleged to be criminal It is not received in proof of the doing of the act or for the purpose of making it more likely in the minds of the jurors that the accused committed the crime charged The proper application of this rule does not infringe on the general rule that it cannot be shown that the accused has committed other crimes But the court on request should clearly limit the scope of the evidence

Basis for Injured Person to Recover for Medical Treatment and Medicine

(Tarrant County Traction Co vs Bradshaw (Tex) 185 S W R 951)

The Court of Civil Appeals of Texas says that one of the physicians who attended Plaintiff Bradshaw and treated him for his injuries attributed to the negligence of the defendant company testified that the reasonable charges for the treatment and medicine which he gave him, if a man was able to pay it, would be $25 The Court thinks this was sufficient to sustain a recovery as to the medical services and medicine The Court says that it does not think the inclusion of the clause, "if a man was able to pay it" would destroy or necessarily limit the force of the testimony to the effect that the reasonable charge for the treatment and medicine would be $25 The Court understands that the witness meant to say, or that at least such was the permissible construction of his language, that the services rendered and the medicine furnished were of the reasonable value of $25, and that the witness regarded the plaintiff legally bound by reason of said services and medicines furnished to pay said sum, but that by reason of the plaintiff's physical and financial condition, he might not be able to pay said amount, if any at all Where a plaintiff is entitled to recover for medical attention and medicines necessary in the treatment of injuries, the defendant is liable, not for the amount actually expended or incurred by the plaintiff, but only for the reasonable or market value of such services, drugs, etc, as were reasonably necessary and for which the plaintiff has paid or has become legally bound to pay The defendant not being a party to the contract of employment between the plaintiff and the physician or nurse, or the contract of purchase between the plaintiff and the druggist, his liability, if at all, is not fixed by the amount paid or promised to be paid by the plaintiff for such services and supplies as were reasonably necessary in the treatment of the injuries, but the defendant's liability is limited to the reasonable or market value thereof In this case the fact that the plaintiff sent for the physician, as testified by the former, and accepted his services, would, in the absence of some other agreement, create a legal liability to pay therefor on the part of the plaintiff Therefore there were services requested, rendered and accepted, and evidence of the reasonable value thereof, which the Court deems to be all the law requires as to this character of proof

CHICAGO MEDICAL SOCIETY

Meeting held Jan 10 1917

The President, DR A AUGUSTUS O'NEILL, in the Chair

Social Insurance Its Bearing on the Profession and the Public as Observed in Great Britain and on the Continent

FRANCIS NEILSON, M P, England Americans are not informed as to the economic industrial, social and religious condition of the British people You cannot understand the genesis of insurance in Great Britain unless you know something about these conditions

Those familiar with the history of the first half of the nineteenth century, and who have relied on newspaper reports for knowledge of current conditions, have assumed that Parliament has reformed certain conditions It is a sad commentary on the economic conditions when you find people agitating for national insurance There was no popular demand for the insurance act It was sprung on Parliament and on the people Perhaps no one was more surprised than Lloyd George himself How was it possible for the Liberals to bring forward a measure that occupied half the time of Parliament without there being any demand for it? The national insurance bill was not in the official program put before the electors six months before the national insurance bill was introduced in the House of Commons In the official program put before the electors in December, 1910, we asked for economic legislation, for constitutional reforms, for better housing laws, for electoral reforms, for educational reforms, and bills for many other things, but not for national insurance It was simply a political dodge

We had had a few years before a royal commission to inquire into the condition of the poor laws Usually in Great Britain when we want to put a rather awkward question out of the way, we form a royal commission to inquire into it

The Poor Law Commission reported that certain evils ought to be remedied by Parliament This commission had the benefit of the investigations of Booth and Rowntree I do not know to what extent the investigations of Booth and Rowntree on social evils are known in America Booth showed that 12,000,000 British people, a little more than one fourth of the population of the United Kingdom, were living on the poverty line We had employers' liability and the friendly societies They did an enormous amount of good But just before the insurance bill was introduced into Parliament, the government received returns from these friendly societies, showing that they were not all solvent but that through precariousness of employment there was something like a quarter of a million paying members lapsing in a year Many of the smaller lodges, particularly in rural areas, were in serious financial condition Under the old friendly society grant there was a great deal of malingering Trade unions were also benefit societies We had also small insurance societies, notably the Provident and the Etna, which catered particularly to the small wage man That was the condition before the bill was introduced

When the royal commission issued its report, the Fabians and socialists got busy The Fabians, headed by Sidney Webb and George Bernard Shaw, drafted a manifesto based on the recommendation of the Poor Law Commission urging that there should be sickness benefit, medical benefit disablement benefit and other benefits given to those who could not help themselves

At the election in December, 1910, candidates had to answer questions from the socialists and Fabians based on the suggestion of the Poor Law Commission The majority of men elected pledged themselves to urge the government to bring in a bill dealing with the recommendation of the Poor Law Commission Lloyd George introduced a social insurance bill in 1911 It was known as the 'fourpence for ninepence measure,' because under the bill the insured worker pays fourpence the employer pays threepence and the state pays twopence, ninepence or 18 cents to be the amount per unit to pay for the scheme of insurance, and for that ninepence the laborer gets medical sickness benefits, disablement benefits consumption benefits and other benefits besides All persons between the ages of 16 and 65, with an income of not more than £150 a year, or $800 were to be insured persons under the act There are one or two exceptions to that The men's funds and women s funds are held separate The full sickness benefit was to be for twenty-six weeks

No sooner was the bill introduced than a storm broke out against it The trade unions at first would have nothing to do with it They said it would disintegrate all the work they had done for generations Domestic servants were to be included Wage earners getting from 25 to 30 or 40 dollars a week arose in disgust against the idea of having to insure domestic servants They said, 'When my servant is ill I pay the doctor for his services, and look after the woman's or man's health I do not want the state to step in and tell me what to do with my servant" Employers objected because the government fixed on them the responsibility of seeing that the employee was insured and that his contributions were paid regularly With the vast amount of casualties among laboring men, chore women, washerwomen and so on, the government saw the difficulty of drawing all the people between the ages of 16 and 65 with an income of less than $800 a year into the purview of the bill Let me tell you of one difficulty in the case of the casual laborer

I live in an agricultural county, and I have a man come one day a week to work in my garden This man works one day a week for me, the next day he works for some one else and so on for six days in the week I asked in the House of Commons who was to be responsible for his insurance money A gentleman on the other side said, We think that the man who employs him the first day in the week should be responsible for his insurance money" And that is the law The man who pays him the first day is responsible for his insurance money

Not long after the bill was in the House of Commons, a bigger storm than any of those I have referred to broke, and that was the storm of the doctors I never knew they had so much energy It was amazing The doctors organized a tremendous agitation against the bill, and the House of Commons for three months or more was receiving objections from doctors from all parts of the country Lloyd George said

The doctors proceeded with their criticisms on five assumptions, all of them erroneous They proceeded on the assumption that the government had fixed the capitation grant They did not The amount of capitation grant was to be fixed by the friendly societies with no appeal to anybody That is not the bill One assumption was that under the capitation grant families were included They were not Another assumption was the system of club doctors was to become universal and not from choice That was not the bill And the last assumption was that all the bad cases were included under the capitation grant They were not The five main assumptions on which the whole of this agitation was based were absolutely erroneous They had absolutely nothing to do with the bill"

He said that the government was making the most liberal provision for the doctors that had ever been made in club practice in England The chief trouble in the minds of the doctors was that if the limit of income was to be $800 a year and the insured was to get ninepence for fourpence, there would be temptation on the part of those whose income was much larger than $800 a year to get within the limits of the bill Many of you are wondering why this arbitrary limit of $800? In England we have an antiquated, effete system of taxation, the so-called income tax Before the war, under the income tax act, incomes of £160 a year and over were liable to taxation One of Lloyd George's excuses for not limiting the bill to those who could not help themselves was that they had no data on the £2 household The £2 household would be the £140 a year house, so they fixed this £160 or $800 because the income tax began at that figure But there is more difficulty in ascertaining in Great Britain the returns from the household of £160 than there is in getting returns from the household of £16 000 Any one who knows the industrial and economic life of the English people must understand the enormous difference in the social position of the family getting £2 and the other family getting £3 The doctors said We know the households and what they can pay better than the treasury We know the members of the family who are working and we know that the arbitrary fixation of $800 a year will mean that many a household that is getting £4 or £5 a week will not pay as much as they ought until each individual worker comes within the purview of the insurance act' They were getting ninepence for fourpence and the government could not stop them

We want you to be wise in your agitation regarding health insurance legislation and not make the mistakes we did in Great Britain We want you to familiarize yourselves with every phase of the subject before securing legislation I suppose in the main that the doctors who attend the very poor were never better off than they are now in Great Britain If you get the state to assure you payment naturally you would favor that system in the majority of cases

After the insurance act went into operation we found that there were resentment and dissatisfaction all over the country A number of amendments had to be passed but I think it is perfectly fair to say that the English act has not had a fair trial in the two years and a few months it was in operation before the war broke out An act of that kind should be tested for at least ten years before final judgment is pronounced on it

Lloyd George was right when he said that this measure was only palliative, it is not curative If it is to be made an effective measure we must deal with the land question So instead of bothering yourselves about national insurance, old age pensions and the blunders that have been made in Germany and Great Britain over social insurance, let me urge you to study fundamental questions economic questions the land question in this country and then get the capital value of the land not only on the surface but as far down as you can go including the ores, the clays, the coals, the slates the marble and everything and put taxation on them and then, when you have opened up the country again, you will find that people having an equal opportunity will not rely on the state, but will get out like men and women and work for themselves and produce in abundance Having abundance and health and leisure, they will find their own souls

DISCUSSION

Dr William A Evans discussed the proposed method of administration of the insurance act

Prof James H Tufts University of Chicago The medical profession owes a duty to these now suffering worse in their health than the more well-to-do members in the community We have a right to ask why so many are suffering and what can be done about it Poorly paid people have much more ill health in proportion than the well to do Part of poverty is due to ill health, just as part of ill health is due to poverty A great deal of the burden of charity is due to ill health It is tremendously to the advantage of the public that the medical profession should receive proper remuneration that it should be well paid to have the best equipment for its work and to encourage the right sort of men to go into the profession The compulsory feature is one of the things we should think about seriously It is necessary in providing for better health of the large group of people who now suffer that there should be a compulsory feature It is more economical to administer a system that includes practically every one than a commercial insurance system in which the expense of collecting is 60 cents on the dollar The larger proportion of people who work are not employed by establishments which make provision for sickness The great proportion of workers are not members of trade unions which pay sick benefits A large proportion of working people are not provided for under the existing scheme The proposed bill does not admit as a carrier any society for profit

Dr Charles J Whalen I agree with Mr Neilson that we are a nation of imitators I believe that social or health insurance has come to stay in this country There is a demand for social insurance largely because eleven European countries have so far adopted it The medical profession of Illinois cannot afford to oppose health insurance We may disagree as to the method of administration, we may not like the tentative draft of the bill, we may have objections to this or that part of the insurance law But to the general subject of health insurance I think we shall have to agree

In England the law has not been in force a sufficiently long time to form a fair estimate of its working value, but in the short time it has been in effect it is claimed that the average income of the physicians in England has materially increased In Germany, where it has been in effect a great many years, the law has materially benefited the medical profession It is claimed that the slums have disappeared, that sickness has materially diminished, and that the average life of the individual of Germany has increased from thirty-six to forty-eight years

Dr K A Zurawski It is not safe to leave legislation which concerns such a large amount of varied interests to self-appointed sociologic bodies The scheme of health insurance which Dr Evans has explained to us is a good example of how a thing should not be Health insurance should consider three different factors the employer, the employee and the medical man Medical men are not represented on these governing commissions, and this is a feature that we should try to correct We want to be full copartners in the administration of health insurance Another point the medical profession should insist on is free choice of medical attendants, but the choice of hospitals or the methods of treatment should not be left to the patient but to the medical man or to a commission of medical men

Dr Carl Beck Having seen some of the work of social insurance organizations in Germany and elsewhere, I can say that they have been unsatisfactory The medical profession in Germany is very much dissatisfied The *Munchener medizinische Wochenschrift* cautions physicians not to take this or that position as health insurance officer It is bad for the people and for the physician In some localities health insurance has done some good, while in others the effect has been the reverse We should study all angles of the question before securing legislation

Mr William Beye, Illinois Steel Company I do not believe that any legislation which destroys individualism is sound The scheme which is proposed is fundamentally state insurance It is the taking over by the state of private endeavor I believe that a man who cannot afford to insure himself in an insurance company or who does not himself provide protection against sickness should be an object of public charity Anything else is contrary to sound fundamental principles In West Virginia, Ohio, Washington and Wisconsin there have been insurance funds established for carrying insurance under the Workman's Compensation Law, and there is not a single fund in any of those states that is solvent, because government as it exists in this country cannot manage an insurance proposition on anything but a wasteful basis Let us consider health insurance as an indemnity after sickness has occurred It does not prevent sickness any more than life insurance prolongs life

Dr William D Pennington The cure for this condition lies in prevention and not in remedial legislation The way to cure this condition is to change the industrial situation, and that can be done only through legislation Following the procedures outlined reduces the people to a condition of semicharity If there is anything which people do not like, it is to feel that they have been forced to resort to charity for protection The way to solve this problem is by legislation that will make it possible to make an honest and comfortable wage The important field in medicine is not curative but preventive, and the way to cure this situation is to prevent it by enacting such laws and establishing such conditions as will make it possible for a man or woman who works in industrial institutions to make a living wage

34 *Further Quantitative Study of Duodenal Blood Derived Pigments, J P Schneider Minneapolis —p 156

26 **Ambard's Coefficient of Urea Excretion**—The coefficient of urea excretion is subject to certain variations in normals but any value below 0 06 or above 0 09, Lewis says, should be regarded as abnormal unless the excessive variation can be readily explained The coefficient is absolutely independent of the blood urea concentration Its level is governed by the condition of renal function The *coefficient is depressed* in fever, in hyperthyroidism in hypertension with early changes in the renal arterioles, and in early chronic diffuse nephritis The depression is an evidence of increased renal activity due to irritation The coefficient is raised in *myxedema* There is an increase of the coefficient in myocardial insufficiency The coefficient is above normal in nephritis with renal insufficiency This increase is more evident in chronic diffuse nephritis than in the vascular type, due to the greater frequency of renal insufficiency in the former cases The coefficient shows an increase long before there is any evidence of nitrogen retention in the blood The coefficient gives an excellent means of following the changes in renal function and of measuring the rate of progress of the disease In a few severe cases the coefficient varies without there being any evident change in the clinical condition The prognostic value of the coefficient is considerable Values above 0 2 are seen only in the severe cases, while constants persistently above 0 3 are found only in persons with a maximal impairment of renal function A coefficient above 0 2 has a graver import in vascular nephritis than in that of chronic diffuse type For an accurate prognosis repeated determinations of the coefficient are of the greatest importance

27 **Action of "Female Remedies" on Strips of Human Uterus**—The action of pulsatilla unicorn root, blue cohosh blessed thistle viburnum, black haw and oil of valerian on strips of human uterus was studied by Pilcher It was found that pulsatilla, aletris and oil of valerian lowered the amplitude of the excursions or completely inhibited them, but the action was not so prompt or so great as on the guinea-pig uterus in the same concentration Caulophyllum put the strips into tonic contraction, but again the action was less than on the guinea-pig the tone was *not* increased above the maximum as was frequently the case with the guinea-pig *Cnicus benedictus* and viburnum were inactive

28 **Present Significance of Amino-Acids in Physiology and Pathology**—In examining both the urine and the blood from a considerable number of patients with toxemia of pregnancy Van Slyke found in no instance that either blood or urine showed an abnormal concentration of amino-acids or of intermediate protein digestion products Consequently, he says, the responsibility for the toxemias of pregnancy cannot be left with the amino acids He has also tested the hypothesis that acidosis is to blame, with essentially negative results

29 **Progressive Muscular Dystrophy**—Timme reports a somewhat atypical form of progressive muscular dystrophy rather resembling Erb s infantile type of extremely benign and slow progress It occurs as a hereditary affection, now in the fourth generation which has disabled fourteen individuals Of the seven living members with the disease, all but two have been examined thus far by Roentgen ray, and of these five, four show distinct changes in the pineal gland producing shadows in the roentgenogram The fifth, a youth of 15 years, whose affliction is rather of different type than the others in that the bony growth is abnormal shows an enlarged sella turcica, but no shadows in the pineal as yet Weighing all the evidence that is advanced by previous investigators to show derangement of the internal glandular balance in cases of progressive muscular dystrophy and giving due significance especially to the changes produced by tumors and diseases of the pineal gland on the various tissues of the body, changes that resemble in character if not entirely in degree or disposition those present in progressive muscular dystrophy Timme says we must admit the extreme probability of a causal relationship between the two If to this probability is adduced the evidence shown by cases of progressive muscular dystrophy of changes in the pineal gland demonstrated by roentgenology, the probability approaches pretty closely to proof that disturbances of the pineal gland play an important role in the pathogeny of progressive muscular dystrophy

30 **Blood Changes After Splenectomy**—Results of splenectomy were studied by Wolferth in sixteen rats whose spleens were presumably normal also in eight rats with enlarged spleens Rats after excision of a normal spleen showed a slight transient anemia, slight tendency to leukocytosis well marked increase in resistance of erythrocytes, no change in percentages of reticulated red cells There was an inconstant increase in the number of nucleated red cells during the periods of anemia Removal of enlarged spleens was followed by rapid and usually fatal anemia hyperleukocytosis marked increase in the number of nucleated and reticulated red cells and, in two cases by distinct jaundice

32 **Nuclear Changes in Red Blood Cells Following Splenectomy**—There can be little doubt, Gilbert says, that a close relationship exists between the loss of splenic function and the appearance of large numbers of nuclear particles in the blood The nuclear particles occur in large numbers within a few hours after the removal of the spleen, and they continue to be present after the blood has become in other respects normal That they occur independent of a primary blood disease is shown by the fact that they occur after the spleen has been removed in normal animals and in men (traumatic rupture of spleen) In no other conditions are they found with such constancy and in such large numbers as after splenectomy Gilbert's studies have shown, further that there is no definite numerical relationship between the nuclear particles and the presence of true nucleated red cells, or any other quantitative or qualitative changes in the peripheral blood His preparations indicate that the nuclear particles originate from otherwise normal nuclei, and that the particles do not show in themselves qualitative degenerative processes

33 **Effect of Heat and Light in Experimental Arthritis**—It is evident from the results of experiments made by Simmonds and Moore that the treated animals were decidedly benefited by heat and light so far as the arthritic manifestations were concerned

34 **Blood-Derived Pigments**—The blood in cases of pernicious anemia and hemolytic jaundice both before and after and with and without splenectomy was studied by Schneider

He found that splenectomy apparently immediately and permanently reduces the excessive blood-derived pigments of pathologic hemolysis to a normal level There is no proof that a recurrence of a pernicious blood and clinical picture after splenectomy is due to a reestablishment of excessive blood destruction A plus hematopoietic-hemolytic index in a given case should, he says, be regarded as one factor favorable to permanent postoperative recovery

39 **Diabetes Mellitus and Syphilis**—Three cases of syphilis, in which the *Spirochaeta pallida* is active and in which the clinical symptoms of diabetes mellitus appeared, are recorded by Barach as occurring among thirty-one cases of diabetes seen within a period of two and one-half years Such cases are supposed to be rare and the relationship of these two diseases is not generally recognized

43 **Unusual Case of Umbilical Hernia**—Lane's patient had suffered for several years from a small incarcerated umbilical hernia The present illness for which she sought aid was ushered in by a severe pain in the mass at the umbilicus This pain persisted three days, when it suddenly ceased During this time the patient vomited nearly twenty times, but whether the vomiting was fecal, was not known On the evening of the second day the vomiting ceased and there were several evacuations of the bowels following a dose of citrate of magnesia On the third day a redness and tenderness appeared about the umbilicus and the hernial mass disappeared On the fourth day the area of redness had extended, and was very much more tender The physical examination was generally negative except for the abdomen The abdomen was somewhat obese and was not distended, but lax and tympanitic These was no protrusion at the umbilicus, but the depression thereof was unusually large and surrounded by an area of redness and tenderness and induration about 6 inches in diameter

An operation was advised and performed At a depth of 1½ inches in the fat about 2 ounces of foul smelling pus were evacuated The pus had an odor characteristic of an appendix abscess After the excess pus had been wiped out there appeared in the upper end of the wound a red mass about the size of a lemon This appeared to be the sac of a hernia with a rent about ½ inch in diameter In the left lower border protruding from this rent was a piece of animal bone, 1⅞ inches long and ⅜ inch wide A piece of small intestine was strangulated in the sac, reddened but not gangrenous, and showing a perforation of ¼ inch in diameter, with its mucous membrane everted

46 **Roentgenologic Report of Cases of Pylorectomy for Ulcer**—Nineteen cases of pylorectomy for ulcer are included in Lindsey's report, with roentgenographic study of seventeen There is prima facie evidence in this series that the stomach, after pylorectomy, tends to enlarge or dilate and thus compensates for the part removed at operation In some cases, in which a wide resection has been performed, the stomach does not seem to have much opportunity or occasion to dilate From the clinical information given all of these patients, with the exception of two, seemed in good condition In general, the efficient manner in which these stomachs have performed their function, at such long periods after operation, testifies to the essential conservatism of an apparently radical operation

50 **Diagnosis of Thyroid Abscess**—Two signs which Lahey found to be present in his three cases are limitation of chin elevation and depression of the chin on the sternum when swallowing These two signs, he believes, are of great significance in cases suspected of thyroid abscess They are brought about by the action of the sternohyoid, sternothyroid and omohyoid muscles on the abscess beneath them Pain results from tightening of these muscles, and this tightening as the result of swallowing may be prevented by depression of the chin on the sternum

52 **Sterilization Treatment of Furunculosis**—The principle of this treatment is simply to keep the skin so far as possible sterile, as free from micro-organisms as it is endeavored to maintain it in abdominal surgery In order to effect this, the patient is directed to take a hot bath morning and night, scrubbing the whole body, including the head, while in the bath with soap After this thorough washing with soap and hot water, the skin is dried, and the whole surface again bathed, this time with a saturated solution of boric acid in water, with the addition perhaps of a small proportion of camphor water After bathing thoroughly with the saturated boric acid solution, the skin is allowed to dry Then the individual furuncles are treated by dressing them with the following ointment spread on cotton or linen and bound lightly on

		gm or c.c	
℞	Boric acid	4	ʒ i
	Precipitated sulphur	4	ʒ i
	Carbolated petrolatum	32	℥ i

This procedure is repeated morning and night Every stitch of linen worn next to the skin should be changed daily, and in the case of extensive furunculosis all the bed clothing that touches the individual, as well as the night clothing, should be subjected to a daily change This treatment has been uniformly successful in Bowen's hands in the treatment of furunculosis

58 Rupture of Intestine Due to Abdominal Trauma Report of Cases W S Conkling, Des Moines —p 20
59 Submucous Resection of Nasal Septum W E Patterson, Waterloo —p *24*

54 **Uremia**—According to the predominance of functional or organic changes, Rowntree points out that it is extremely important to recognize whether the case is one in which the uremia is due to organic or functional changes The development of uremia in a case of marked chronic interstitial nephritis offers little in a permanent way as a result of treatment, whereas in an identical clinical picture encountered in back pressure kidney such as seen in cases of enlarged prostate, the prognosis may be good This is familiar to the surgeon but not as a rule to the internist Rowntree refers to instances in which following the use of the constant catheter, forcing of fluids, and limitation of nitrogen intake

uremia has disappeared and in some instances, following a subsequent prostatectomy, renal function has returned practically to normal In the vast majority of cases the treatment adopted is based on the theory of retention of products of metabolism When edema of the brain is present the question of mechanical relief of cerebral pressure may need to be considered Lumbar puncture may be of the greatest value in cases with marked headache dependent on cerebrovascular changes If acidosis coexists alkalies should be administered but only to the point of correcting the acidosis not indiscriminately in all cases of uremia nor in the large amounts recently advocated In every case of uremia it is the physician s duty to determine if possible the underlying cause and to treat the case accordingly

65 **Allantoin in Blood** —From the blood of the ox and the pig allantoin was obtained by Hunter in quantity sufficient for positive identification while its presence in that of the horse and the sheep was rendered practically certain Human blood on the other hand yielded no evidence of containing even a trace of allantoin

66 **Iodin Content of Food Materials** —It would appear from Bohn s studies that the presence of iodin in feeding materials of vegetable origin is accidental and serves no necessary nutritive function in the plant

74 **Infant Feeding Chemical Changes Produced by Addition of Lime Water to Milk** —The addition of lime water to milk which normally contains some insoluble dicalcium phosphate Bosworth and Bowditch found results in the precipitation of more calcium phosphate, the insoluble phosphates under these conditions being a mixture of dicalcium and tricalcium phosphate, $CaHPO_4$ and $Ca_3P_2O_8$ The addition of lime water to milk brings the reaction of the serum toward the neutral point, the soluble alkalinity of the lime water being used up in the precipitation of the insoluble calcium phosphates mentioned above When milk to be used for infant feeding is treated with lime water and finally diluted to such an extent that it has twice the volume of the original milk or more the soluble calcium and phosphorus may be reduced to amounts less than those which are present in human milk

80 **D-Mannoketoheptose, New Sugar from Avocado** —La Forge describes the isolation of a new ketose sugar containing seven carbon atoms from the fruit of avocado or alligator pear The sugar exists in the free state in the fruit The new sugar is both a ketose and a heptose and is accordingly the fourth natural ketose to be isolated the other three being fructose sorbose and ketoxylose and is the first heptose to be found in nature the previously known heptoses having all been prepared synthetically from hexoses

83 **Tissue Reactions to Products of Tubercle Bacillus** — The tubercle bacillus according to Morse and Stott produces a microscopically characteristic lesion not because it is a living particulate protein, but because its waxy substances act as a peculiar type of foreign body

84 **Tonsillectomy During Acute Rheumatic Fever** —With the subsidence of outward evidence of acute inflammation of the tonsils Morris says the danger of allowing them to remain in the body probably exceeds the danger of their removal In all cases he believes an attempt should be made to relieve the joint tenderness by full doses of salicylates, before the operation is attempted A certain amount of freedom of movement is necessary after the operation, to enable the patient to expectorate etc , during the height of an acute arthritis, pain on moving would often prevent the necessary changes in position

85 **Bacteriemias in Agonal Period** —Routine blood cultures taken by Fredette immediately after the death of 119 individuals reveal the presence of an unsuspected bacteremia in about one third of all fatal cases Streptococci are the most frequent terminal bacterial invaders of the blood stream The pneumococcus can be isolated in practically all cases of lobar pneumonia dying before the tenth day of the disease

96 Dispensary Work in Diseases of Nervous System S E Jelliffe New York —p 46

94 **Histopathology of Autonomic Nervous System** —The thoracicolumbar semilunar and intestinal ganglia in seventeen cases were studied by Morse in connection with the central nervous system and the ductless glands The cases

comprise two each of pellagra, senile dementia, paresis, cerebral syphilis, generalized (including cerebral) arteriosclerosis and one each of pernicious anemia, imbecility plus mitral insufficiency, dementia praecox plus lobar pneumonia, alcoholic dementia and generalized tuberculosis, manic depressive insanity and carcinoma of stomach, involutional depression and katatonic "hirntod" In no instance were the ganglia normal In the cerebral syphilis cases, however, the changes were rather insignificant The conditions found are grouped as acute and chronic degenerative changes in the nerve cells, and exudative manifestations in the stroma Chronic degenerative changes in the ganglion cells predominated, as would be expected, in the chronic organic nervous diseases (paresis, senile dementia and cerebral arteriosclerosis) They were also found in ganglia in the vicinity or organs showing chronic lesions Acute changes predominated in the case of katatonic "hirntod" (brain death), and in the local ganglia in certain pathologic conditions, as valvular heart disease and acute enteritis and peritonitis Both acute and chronic conditions and those which might be either, as axonal reaction and neurophagia were present in pellagra, pernicious anemia, tuberculosis and involutional depression A point of interest and importance is the special incidence of lesions in the ganglia, and their possible correlation with adjacent visceral conditions In several instances the lesions were not universally distributed, but were limited to ganglia in the vicinity of affected structures In an agitated depression changes suggestive of fatigue processes were found in the thoracicolumbar chain of ganglia, and in a case of katatonic "hirntod" marked lesions of an acute degenerative type, associated with neurophagia

140 Abstracted in The Journal, June 3, 1916, p 1815

142 **Cerebrospinal Syphilis**—Ten cases of cerebrospinal syphilis, 11 cases of tabes dorsalis, 20 cases of general paresis and 9 cases of taboparesis were studied by Sutter Most of these examinations were made after the patients had been given considerable treatment The globulin reaction was present in 7 cases, weakly positive in 2, and negative in 2 out of the 11 cases The cell count increased in 8, normal in 1, and borderline in 2 cases The highest count was 55 The Lange gold chlorid reaction in this series of 11 cases did not show any characteristic curve Five cases showed some color

changes but no marked color changes in the tubes were seen except in 2 cases which also showed a large increase in globulin and in the cell count The Wassermann reaction was positive in the serum in 5 cases and in the fluid in 7 cases out of 11 cases In 1 case it was negative in the serum and positive in the fluid In all the other cases the findings were consistent One case had decided ataxia but no other clinical signs It was diagnosed as irregular tabes The strongest and most characteristic reactions were seen in this series of 20 cases of paresis All cases showed well marked color changes in the Lange colloidal gold chlorid reaction The typical "paresis curve" was seen in all the tests The highest cell count was 50 It was normal in 2 cases and there was only a slight increase in another The globulin was positive in 16 cases, weak in 2 cases and negative in 2 cases The Wassermann reaction was positive in every case except 2 One case showed negative reaction in the serum and positive in the fluid Nine cases of taboparesis were studied In all cases all the tests were positive

160 **Removal of Stones from Kidney**—From Jan 1, 1898, to Dec 31, 1915, 450 patients with stone in the kidney were operated on in the Mayo Clinic (484 operations) Three died, a mortality of 0 6 per cent This percentage represents the number of patients who died in the hospital without regard to cause of death or length of time after operation Mayo says that the results achieved were due more to the painstaking care with which the diagnoses were made, the function of the kidney estimated, and the patients prepared for operation, than to any purely technical feature of the procedures employed in removing the stones The presence of the stones was shown by the roentgenogram By means of the pyelogram the urologist was able to say with certainty whether the stone was in the pelvis calyx, or parenchyma of the kidney Forty-eight patients (99 per cent) had stones in both kidneys In these cases, the second kidney was found pyonephrotic a condition necessitating nephrectomy In three instances stones were found in a single kidney and in two instances in a horseshoe kidney The condition was diagnosed before operation as nephrolithiasis in an anomalous kidney In one case of horseshoe kidney the stone had caused a pyonephrosis in the left half This portion of the kidney was resected and recovery followed Renal stones were found in two patients with duplication of the renal pelves In both, the caudal pelvis was involved, in one a pelviolithotomy sufficed but in the other a resection of the upper half of the kidney was necessary

There were two cases of stones in the remaining kidney after nephrectomy Multiple stones in the parenchyma of the kidney are prone to recur In one case in which Mayo removed twenty-eight stones from one kidney and twenty-six from the other, he reoperated on the patient within two years for stones in both kidneys The following operations were performed pelviolithotomy, 206 cases, combined pelviolithotomy and nephrolithotomy, 34 cases, nephrolithotomy, 40 cases and nephrectomy, 204 cases

164 **Hematocolpos in Woman of Seventy-Four**—In a woman of 74 who had menstruated normally until thirty-five years previously, severe pain, pointing to obstruction of the urinary flow, led to the detection of a large fluctuating tumor which filled the entire plevis and extended upward almost to the umbilicus The vagina was occluded by senile atresia Laparotomy in spinal anesthesia revealed the tumor to be an enormous hematometra and hematocolpos with bilateral hematosalpinx Panhysterectomy was performed successfully by Gellhorn, and the tumor, which was connected with the vagina only by loose connective tissue was removed unopened Convalescence was undisturbed, the patient left the bed on the twelfth day after operation but succumbed to an embolism on the fifteenth day The cause of bleeding into the occluded genital tract was an adenocarcinoma of the body of the uterus

169 **Differential Diagnosis of Pyuria**—If urine is not obtained by ureteral catheterization the catheter is withdrawn from the ureter, and a second catheter passed In the event of persistent failure of urinary flow, an empty Luer syringe is applied to the large end of the ureteral catheter which had been used first, and the catheter contents are forced out on a glass side Curtis says that examination of this material yields a diagnosis in most '*dry tap*' *pus infection* cases Usually there is considerable stringy mucoid material in addition to other pathologic constituents This procedure has several times clinched a diagnosis when it would otherwise have been impossible, or possible only by exclusion

170 **Hemostasis by Interposition of Muscle, Fat and Fascia**—Risley reports the results of experimental work on the use of these tissues in stopping hemorrhage in such organs as the kidney and liver, when other forms of hemostasis are either impossible or undesirable The interposed tissue is taken from the patient s own body at the time of operation

comprise two each of pellagra, senile dementia, paresis, cerebral syphilis, generalized (including cerebral) arteriosclerosis and one each of pernicious anemia, imbecility plus mitral insufficiency, dementia praecox plus lobar pneumonia, alcoholic dementia and generalized tuberculosis, manic depressive insanity and carcinoma of stomach, involutional depression and katatonic "hirntod" In no instance were the ganglia normal In the cerebral syphilis cases, however, the changes were rather insignificant The conditions found are grouped as acute and chronic degenerative changes in the nerve cells, and exudative manifestations in the stroma Chronic degenerative changes in the ganglion cells predominated, as would be expected, in the chronic organic nervous diseases (paresis, senile dementia and cerebral arteriosclerosis) They were also found in ganglia in the vicinity or organs showing chronic lesions Acute changes predominated in the case of katatonic 'hirntod" (brain death), and in the local ganglia in certain pathologic conditions, as valvular heart disease and acute enteritis and peritonitis Both acute and chronic conditions and those which might be either, as axonal reaction and neurophagia were present in pellagra, pernicious anemia, tuberculosis and involutional depression A point of interest and importance is the special incidence of lesions in the ganglia, and their possible correlation with adjacent visceral conditions In several instances the lesions were not universally distributed, but were limited to ganglia in the vicinity of affected structures In an agitated depression changes suggestive of fatigue processes were found in the thoracicolumbar chain of ganglia, and in a case of katatonic 'hirntod" marked lesions of an acute degenerative type, associated with neurophagia

160 **Removal of Stones from Kidney**—From Jan 1, 1898, to Dec 31, 1915, 450 patients with stone in the kidney were operated on in the Mayo Clinic (*484 operations*) Three died, a mortality of 0 6 per cent This percentage represents the number of patients who died in the hospital without regard to cause of death or length of time after operation Mayo says that the results achieved were due more to the painstaking care with which the diagnoses were made, the function of the kidney estimated, and the patients prepared for operation, than to any purely technical feature of the procedures employed in removing the stones The presence of the stones was shown by the roentgenogram By means of the pyelogram the urologist was able to say with certainty whether the stone was in the pelvis calyx, or parenchyma of the kidney Forty eight patients (9 9 per cent) had stones in both kidneys In these cases, the second kidney was found pyonephrotic, a condition necessitating nephrectomy In three instances stones were found in a single kidney and in two instances in a horseshoe kidney The condition was diagnosed before operation as nephrolithiasis in an anomalous kidney In one case of horseshoe kidney the stone had caused a pyonephrosis in the left half This portion of the kidney was resected and recovery followed Renal stones were found in two patients with duplication of the renal pelves In both, the caudal pelvis was involved, in one, a pelviolithotomy sufficed but in the other a resection of the upper half of the kidney was necessary

There were two cases of stones in the remaining kidney after nephrectomy *Multiple stones in the parenchyma* of the kidney are prone to recur In one case in which Mayo removed twenty-eight stones from one kidney and twenty-six *from the other, he reoperated on the patient within two years* for stones in both kidneys The following operations were performed pelviolithotomy, 206 cases, combined *pelviolithotomy and nephrolithotomy*, 34 cases, nephrolithotomy, 40 cases and nephrectomy, 204 cases

164 **Hematocolpos in Woman of Seventy-Four**—In a woman of 74 who had menstruated normally until thirty-five years previously, severe pain, pointing to obstruction of the urinary flow, led to the detection of a large fluctuating tumor which filled the entire plevis and extended upward almost to the umbilicus The vagina was occluded by senile atresia Laparotomy in spinal anesthesia revealed the tumor to be an enormous hematometra and hematocolpos with bilateral hematosalpinx Panhysterectomy was performed successfully by Gellhorn, and the tumor, which was connected with the vagina only by loose connective tissue, was removed unopened Convalescence was undisturbed, the patient left the bed on the twelfth day after operation but succumbed to an embolism on the fifteenth day The cause of bleeding into the occluded genital tract was an adenocarcinoma of the body of the uterus

169 **Differential Diagnosis of Pyuria**—If urine is not obtained by ureteral catheterization the catheter is withdrawn from the ureter, and a second catheter passed In the event of persistent failure of urinary flow, an empty Luer syringe is applied to the large end of the ureteral catheter which had been used first, and the catheter contents are forced out on a glass side Curtis says that examination of this material yields a diagnosis in most "dry tap' pus infection cases Usually there is considerable stringy mucoid material in addition to other pathologic constituents This procedure has several times clinched a diagnosis when it would otherwise have been *impossible*, or possible only by exclusion

170 **Hemostasis by Interposition of Muscle, Fat and Fascia**—Risley reports the results of experimental work on the use of these tissues in stopping hemorrhage in such organs as the kidney and liver, when other forms of hemostasis are either impossible or undesirable The *interposed tissue is* taken from the patient's own body at the time of operation

Muscle tissue is the ideal hemostatic In order most effectively to stimulate fibrin formation it should be cut jaggedly with a knife and not crushed as with a scissors cut, nor should its hemostatic properties be extracted by its contact with salt solution Fascia and fat act to a more limited degree as hemostatics, fascia more than fat, but both very much less than muscle In the liver, however, both fascia and fat seem at times to be very efficient hemostatics These tissues readily unite to the bleeding surface to which they are sewed and form a smooth, solid scar Microscopic examination of specimens removed at varying intervals after operation show in Risley's series absence of sepsis, a beginning transformation of muscle into fibrous tissue, a partial absorption of fat and change into fibrous tissue, no change in fascial transplants, in practically every case a firm blending of the interposed tissue with the cut surface of the parenchymatous tissue, the formation of new blood channels and no degenerative changes of any note

176 **Reestablishing Patency of Ureter in Pyonephrosis**—In Molony's case a catheter was passed into the kidney with the aid of the cystoscope and brought out through a nephrostomy wound in the loin To the point of this was sewed a No 11 catheter After removing the cystoscope, traction was made on the small catheter bringing the large one down through the kidney and bladder and out through the urethra The catheter was drawn out as far as possible so that the largest diameter of it was in the pelvis and upper portion of the ureter Six or 8 inches of the tip of the catheter were cut off close to the urethra and a strong plaited silk ligature was attached to the cut end By pulling on the upper end in the wound the lower end was drawn up into the bladder with the plaited silk ligature hanging out through the urethra This piece of silk ligature caused no irritation in the urethra, it also gave control from both ends when it was necessary to move the catheter up or down and adjust the lower end of it so as not to irritate the neck of the bladder The catheter in the kidney, the ureter and bladder caused no inconvenience whatever, and the bladder was irrigated with solutions daily by inserting the nozzle of an irrigator into the upper end of the catheter projecting out of the wound The large catheter was changed every few days by inserting an extra long wire stilet through it, withdrawing the catheter and inserting a fresh one over the stilet The catheter was removed after three weeks The patient increased in weight and vigor and was able to go about soon after the catheter was removed By inserting the nozzle of an irrigator into the fistula, a pint of solution could be run through into the bladder in a few minutes, thus proving the patency of the ureter

5 **Cytologic Examination of Joint Fluid**—Starting from the point that normal synovial fluid of the knee joint is acellular, Lazarus-Barlow says that when gunshot injury occurs and hemorrhage takes place into the synovia the ratio of leukocytes to erythrocytes found immediately must be that of normal blood, say, one leukocyte to 500 red cells With the subsequent migration of leukocytes due to inflammatory reaction the number of white cells goes up Thus he has notes of cases in which the ratios of leukocytes to red blood corpuscles were 3 500, 5 500, 9 500 25 500, 50 500, 70 500, 125 500, 1,000 500 Further, normal blood contains roughly 70 per cent polynuclears, 30 per cent mononuclears, and the leukocytes found in the mixture of synovial fluid and blood immediately after the injury must be present in these ratios If the subsequent migration of leukocytes be called forth by an "aseptic irritant" the ratio will remain unchanged or the percentage of mononuclears may ever increase If the migration be called forth by a "bacterial irritant" the polynuclear percentage will increase Hence, if a sample of knee joint fluid removed from a patient in a hospital shows, for example, 500 reds to five whites, and a differential count of the whites shows 50 per cent polynuclears and 50 per cent mononuclears, it differs fundamentally from another sample showing, for example one red to four white, when the whites on differential counting are 99 per cent polynuclears and only 1 per cent mononuclears The case from which the first sample was taken is clearly one in which infection is absent or negligible, the second is one in which it has undoubtedly occurred In all Lazarus-Barlow has examined fluids and given prognoses in eighty-nine cases

13 **Gland Index in Tuberculosis**—There is abundant pathologic evidence to prove the frequency of enlargement of the bronchial and cervical glands in small children in cases of early pulmonary tuberculosis, and also as a primary manifestation of the disease in cases in which the lungs have not been affected It would seem probable, moreover, both on clinical and pathologic grounds, that tuberculous infection in small children tends to enter the system via the upper part of the alimentary canal, the mouth, tonsils, fauces, etc, rather than through the respiratory tract This would explain the frequency with which children exposed in their homes to infection from consumptive parents are found to suffer from tuberculous cervical glands During the course of Lankester's investigation it was a constantly recurring experience to obtain from schoolchildren, showing glandular enlargement in a marked degree, the clearest possible recent history of tuberculosis contact No prolonged examination of individual cases was made, the children were placed in lines and examined in succession by the two hands, one on each side of the neck The submaxillary and cervical regions alone were palpated and all cases were marked as negative in which enlargement of the lymphatic glands was not instantly apparent It was found that after the age of 12 years the percentage of cases of enlarged glands rapidly declined, showing that the enlargement itself is in most cases—whatever be its cause—of a temporary nature The percentage of such cases among about 240,000 children examined in 1913, was 10 5 falling to 8 8 in 1914

26 **Plant Hairs as Pseudoparasites**—An examination of the stools of a patient admitted to the hospital on account of diarrhea revealed the presence of large numbers of bodies which at the first glance resembled ancylostoma, and in addition small bladder-like structures The former had a hooked pointed tip, while the other end, which was somewhat expanded, showed the presence of small spines The whole appearance suggested the male form of ancylostoma The size, however, was entirely against its being such, the largest being roughly 300 microns Moreover, no oral aperture and no evidence of any internal organs could ever be detected and no ova could be found The patient's blood while showing a slight degree of anemia, gave no evidence of eosinophilia A consideration of the foregoing facts pointed to the bodies as being plant hairs, and after further investigation they were identified as the grapnel hairs of the common runner bean

45 *Sign of Glossopharyngeal Paralysis M Vernet—p 551
46 Simplified Technic for Quantitative Test for Sugar (Dosage du glucose) P Vansteenberghe and L Bauzil—p 556

40 **Vaccine Therapy of Typhoid**—Petzetakis reports in detail two cases of typhoid in which vaccine therapy was applied by the intravenous route, without any other measures The patients were men of 23 and 30 and the fever subsided, in both, the first or second day after the first or second intravenous injection of the vaccine Similarly prompt results were obtained in five cases of typhoid in another's service, given the intravenous treatment The charts show the unmistakable influence on the fever from the vaccine given the eighth and thirteenth day in one case and the tenth day in the other

43 **Attenuated Myocarditic Symptoms with Sciatic Neuralgia and Cervical Rheumatism**—Nobecourt and Peyre have encountered a number of cases in soldiers in which sciatica and meningeal reactions, manifest in the cerebrospinal fluid, were accompanied by rheumatic disturbances in the neck and dilatation of the heart without other symptoms of latent myocarditis Such cases are usually labeled cerebrospinal meningitis at first but this is rendered untenable by the rapid improvement under rest in bed, lumbar puncture and sodium salicylate No symptoms attract attention to the heart but it will be found enlarged and the patient should be given a leave of absence for convalescence for a month or two After this if the heart is still enlarged, whether the beat is regular or not the man cannot be considered cured, and should be sent to a sanatorium to recuperate further The same principle should be applied to convalescents from acute articular rheumatism, typhoid or paratyphoid, scarlet fever, etc

45 **Glossopharyngeal Paralysis**—Vernet states that paralysis of the superior constrictor of the pharynx is generally responsible for difficulty in swallowing solid food This muscle is innervated by the glossopharyngeal nerve Paralysis of the pneumogastric or spinal nerve does not entail this difficulty in swallowing solids Another feature of paralysis of the superior constrictor is a curtain movement of the posterior wall of the pharynx from the affected side toward the sound side There is also disturbance in the sense of taste of the posterior portion of the tongue when the glossopharyngeal nerve is profoundly altered or has been severed The diagnosis of glossopharyngeal paralysis may aid in determining the site and extent of other associated paralysis His chart showing his conception of the innervation of the pharynx differs in several respects from those of the textbooks

56 *Throbbing in Felons etc (De la sensation du 'doigt qui bat dans le panaris) R Lutembacher—p 597

48 **Pellagra**—Sambon has maintained for eleven years that pellagra is probably an infectious disease, possibly the work of some protozoon which is transmitted by the sting of some winged insect Recently he has studied pellagra in the various foci of pellagra in Europe, the United States and the Antilles, and he has established its presence in the British Isles in British Guiana and in several parts of France He has noted the prevalence of pellagra in quite young children in the endemic foci, also the great importance of the disease as a cause of insanity He says that the history of pellagra as he traces it through the centuries and in different countries shows that it occurs in certain regions, like sleeping sickness, and that those endemic foci remain permanent Outside of the endemic foci the disease can neither be contracted nor transmitted No instance is known, he affirms, of transmission of the disease in the hospitals or asylums to the medical or nursing force or other inmates, or from a pellagrin to her nursing infant In the endemic foci the disease is inevitably contracted, and usually within the first year The period of incubation may be less than two weeks The youngest pellagrin he has encountered was a 3 months babe The recurrences of the disease are like those of malaria, the flare-up may occur in March while the new cases develop later, in April, May or June In conclusion Sambon remarks that pellagra was known in Europe long before the introduction

of corn from America, and the geographic distribution of the cultivation or consumption of corn does not coincide with the distribution of pellagra, while prophylaxis based on the corn theory has proved futile

54 **Recurring Tuberculous Pleurisy**—Piery calls attention to this benign and common form of tuberculosis He discusses the factors, the symptomatology and the pathogenic import of this affection which subsides in two or three weeks under proper treatment, but is liable to return again and again when the same etiologic factors are encountered anew In about 25 per cent of the cases there is a little patch of cortical pneumonia below the pleurisy The part of the pleura involved is usually at one or both of the fissures of the lungs, and these fissures should be ausculted when we have a patient with symptoms suggesting bronchitis

56 **The Throbbing in a Felon, etc**—Lutembacher ascribes the throbbing in a felon and in certain abscesses headaches, etc, to the concentric pressure from the edema which raises the arteriole pressure to the level of the diastolic pressure, so that the arterial walls vibrate with each systole

Progrès Médical, Paris

December 20 1916 XXXI No 24 pp 233 244

57 *The Scientific Literary Output of the War (Des enseignements de la guerre germanique sur le front français) E Delorme —p 233
58 *Treatment of Ulcerative Sore Throat and Stomatitis (A propos du traitement de l'angine de Vincent et des stomatites ulcero membraneuses) F Ramond —p 241

60 Deforestation and Depopulation in Certain Districts in France (*La depopulation de nos campagnes*) A Satre —p 243

57 **The Scientific Literary Output of the War**—Delorme *is medical inspector general of the French army, and he* remarks that not only the unprecedented number of the wounded but the fact that three fourths of all the physicians and surgeons of France have been engaged in war surgery and the stability of the fighting line, have rendered possible the patient study of data and control of methods Repair of wounded nerves soon became the impassioned study of surgeons and neurologists, as the frequency of paralysis attracted attention He adds, "The number of stiff and ankylosed joints soon roused surgery to feel the responsibility for its previous inexcusable disdain for long treatments Surgery even now will not admit the share in these deformities that belongs to apparatus which undoubtedly simplified surgical treatment at first but too often compromised the ultimate outcome However this may be, the results we see, and often they are regrettable Mechanotherapy has shown itself to be merely palliative" Delorme then reviews the works that have been published in book form, and in the medical and surgical journals mentioning in detail the more important communications on war surgery

58 **Treatment of Ulcerative Stomatitis and Vincent's Angina**—Ramond cleans out each ulceration mechanically, then applies silver nitrate The patient gargles first with a 1 per cent solution of cocain In five minutes the ulceration can be cleaned out If there is slight hemorrhage this can be arrested by gargling with a solution of hydrogen dioxid The cavity of the ulcer is then dried with cotton and then touched with a tampon moistened with a 1 50 solution of silver nitrate The procedure is not painful but it has to be repeated daily for two or three days The technic is the same for ulcerative stomatitis except that he sometimes uses a hard brush instead of the blunt curet to clean out the ulceration

Revue de Chirurgie, Paris

1916 XXXV No 6 pp 781 914

61 *Classification and Treatment of Crippling Callus Production in the Ankle (Cals vicieux du cou de pied) J Tanton —p 781
62 Extraction of Projectiles in the Pelvic Region G Leo —p 810 To be continued
63 *Primary Tumors of the Aponeuroses G Bolognesi —p 876
64 Ligation of Carotid Artery or Its Branches for War Wounds of Vessels Eleven Cases (Plaies vasculaires des regions cervicales et cervico-faciales)—J Gatellier —p 899

61 **Deforming Callus of the Ankle**—Tanton remarks that any vicious consolidation of the ankle upsets the balance of the foot on the leg either sideways or forward and back, and there are numerous varieties of each form of disturbance Radiography is indispensable and he explains how to interpret the findings Valgus flatfoot includes deviation of the axis of the foot as well as the sinking of the plantar arch, and it is important to detect even minimal disturbance of the kind as a guide to treatment It is revealed by the imprint of the two feet side by side The sagittal planes of the two feet then form an angle of 14 degrees, the two lines meeting at a point just as many inches back of the heels as the feet are long A perpendicular line between the diverging lines shows the slightest deviation from normal Another test is by outlining the foot with a pencil and then working the pencil under the sole to outline the region where the sole is not in actual contact with the paper on which it is standing

63 **Primary Tumors of the Aponeuroses**—Bolognesi analyzes the cases on record of a primary tumor developing in the membrane of the aponeurosis and reports the details of three cases of the kind One was an ossifying fibroma of the thigh in a farmer of 22 The second was a giant cell sarcoma of the fascia lata of the left thigh in a woman of 77 The third was a hard fibroma of the left iliac aponeurosis in a young woman The tumors had been first noticed from two to four months before their removal, the first patient had been kicked in the region by a horse and the tumor had been noticed soon afterward

71 Special Diet Food Cards Seldom a Reliable Basis for Morbidity Statistics (Nahrungsmittelatteste und Statistik) H Kohn —p 1283

65 **Principles for Management of Kidney Disease**—Umber classifies pathologic kidneys in three groups, 1, those with degenerative processes in the epithelial segments of the kidney—the nephroses, 2, those with inflammatory processes in the glomeruli, and 3, those with primary arteriosclerotic changes in the smaller kidney vessels The prognosis in the first type is good, in only three of his forty-eight cases of nephrosis did the condition progress to shriveling (amyloid contracted kidney in two of the three) There was neuroretinitis in five of his 170 cases of acute glomerular nephritis, although in two of the five the kidney affection had subsided Acute glomerular nephritis usually subsides under proper treatment, otherwise it passes into a chronic phase This acute type is the one observed in soldiers on active duty, cold and wet predispose to it but the actual cause is toxic action, streptococci and certain bacteria having apparently a special affinity for the glomeruli

He insists that the degree of albuminuria is of no import for the prognosis The highest albumin content is found in the first, the mildest and most curable type, the nephroses—which in their acute and subacute phases correspond to the old conception of parenchymatous nephritis Albuminuria is merely a sign that the kidney is not entirely intact It has absolutely no bearing on the prognosis in comparison to the tests of the diluting and concentrating power of the kidney, the retention of nitrogen, and the blood pressure findings The same may be said of the formed elements in the urine, the sediment is most striking in the first type, the nephroses, but it is of little import for the prognosis unless blood corpuscles in the kidney urine suggest involvement of the glomeruli

This classification allows rational treatment as, in sparing the kidney, all we need to spare is the special function which has become impaired In the first type, the nephroses, the elimination of water and salt is defective and there is a tendency to edema Consequently in this form it is better to refrain from attempts to flush out the kidneys by copious ingestion of water Salt also should be restricted The trouble is extrarenal, the vessels outside of the kidneys having become abnormally permeable under toxic influences Restriction of water is the more rational under these conditions as the sewerage power of the kidneys is not impaired otherwise Restriction to milk is wrong, as there is too much salt and fluid in the milk, if enough milk is taken to supply the needed calories, 3 liters of milk contain 5 gm of salt With chronic nephroses the elimination of water proceeds approximately normally so the intake need not be reduced

In the second type, glomerular nephritis, when acute he orders 1 5 liters of fluid a day In the second stage of the chronic form, manifested by albuminuria and gradually rising blood pressure dietetic measures have no influence although excesses in eating and drinking should be avoided In the third stage, fluids should be given up to 3 liters a day to postpone uremia unless there are cardiovascular contraindications The same applies also to the malignant form of the third type, sclerosis of the finer kidney vessels The benign type does best with restriction of fluids as this spares the heart and peripheral vessels, he warns against more than 1 or 1 5 liters of fluid a day in this type The first type, the nephroses, do not require restriction of albumin in the diet, but this is imperative in glomerular nephritis at all stages and in the malignant form of the third type It is astonishing how the azotemia and with it the subjective disturbances subside when the intake of nitrogen is restricted The albumin content of a liter of milk—5 5 gm nitrogen—is more than azotemic nephritics can stand From 3 to 5 gm a day is the limit for them The salt should be limited to 5 gm a day this amount can be taken in acute glomerular nephritis as well as in azotemic and sclerotic nephritis, but it is far too large in the first type, the nephroses, and also when glomerular nephritis is associated with a nephrosis, unless there is no tendency to edema

Venesection is useful in azotemic kidney disease, especially when combined with intravenous hypotonic saline or a 4 1 per cent grape sugar solution With uremic convulsions from swelling of the brain, when there is retention of water and salt as in glomerulitis plus nephrosis, lumbar puncture is the sovereign remedy

In the first type, the nephroses, the retention of salt and water is due to extrarenal causes to abnormal permeability of the vessels elsewhere We know of no drugs that will modify this toxic permeability, but it corrects itself, often suddenly and unexpectedly so that the fluids pass on into the kidneys and diuresis is increased, regardless of what drugs may or may not have been given This, he exclaims is unfortunately often attributed to the medicines that have been given Hence the vogue of diuretics Umber thinks that their efficacy in kidney disease without cardiovascular disturbance is but slight They may increase the output of water a little in azotemic kidney disease but the elimination of waste products is not increased by them The drugs given are also liable to be retained themselves and have dangerous cumulative effects This is particularly menacing with digitalis and strophanthin in the malignant form of the arteriosclerotic kidney

He defines the clinical picture of the first type, the nephroses, as normal or nearly normal blood pressure no retention of nitrogenous waste and no secondary cardiovascular disturbances but extrarenal retention of salt and water the concentrating and diluting power of the kidney unimpaired The third type, the arteriosclerotic in which the finer kidney vessels are the seat of primary sclerotic changes, may be merely one part of a general tendency to arteriosclerosis In the benign form the kidney disturbances are overshadowed by those from the arteriosclerosis in the heart or brain, but still they are responsible for the high blood pressure with slight or no albuminuria and for the tube casts When the kidney disturbances predominate, we have the malignant form the chronic interstitial nephritis of the old school true contracted kidney in its narrower sense Analysis of his 150 cases of sclerotic kidney has demonstrated that the outcome of the cases—whether they are to be benign or malignant—depends on whether the glomeruli get a chance to functionate properly or not When they can work properly, the kidney trouble is of minor importance, and the patient dies at last from the heart or brain arteriosclerosis

68 **Death Rate in Relation to Birth Rate in Families**—Hamburger tabulates statistics from 1,042 families in 1908 and 1 047 in 1913 showing the number of conceptions and of children surviving to the sixteenth year The figures show a constant decline from over 76 per cent surviving to the sixteenth year in families with one child and over 66 and 72 per cent in families with two children to only 30 66 and 30 37 surviving in the families with most numerous conceptions The number of children that died also showed a constant increase from the one and two children families to the more numerous families

80 Field Bedstead (Eine Feldbettstelle) K Laubenburg —p 1486

74 **Paratyphoid Ostitis**—Boring pains in the legs, suggesting ostitis, accompanied by leukopenia and relative lymphocytosis seem to be a tardy phase of paratyphoid B infection testifying to renewed toxic injury of the blood-producing system Stephan relates that only 10 per cent of the numerous cases of paratyphoid B that he has encountered presented the classic clinical picture of abdominal paratyphoid or paratyphoid gastro-enteritis In 80 per cent the disease ran a protracted course indicating a chronic infection of the blood-producing system the lymph glands spleen and bone marrow In this chronic course a wave of renewed toxic action on the bone marrow may cause pains suggesting a new and different infectious process in the bone involved This may occur without any rise in temperature but the number of leukocytes drops and the proportion of lymphocytes increases Stephan suggests that one reason for the different course of infectious diseases in military and civilian circles is that direct contact is mainly responsible for the infection in army circles, while elsewhere contamination of food etc, must be incriminated

78 **Gumma and Gout Involving Upper Vertebrae**—The first instalment of Hnatek s communication was summarized on page 230 He here describes a case of supposed Rust's disease in a man of 35 who had had for four months pains and stiffness in the suboccipital vertebrae It proved to be the work of a syphilitic gumma and, after this had retrogressed under specific treatment, a defect was left in the arch of the atlas In another case described a woman of 48 had been subject to intense migraine from childhood At the menopause it had become transformed to neuralgia in the occiput radiating to the temples Typical attacks of gout had occurred at times during the last ten years, mostly in the hands and arms, one joint becoming affected as another returne

approximately normal, each attack dragging along for weeks Finally the occiput region became very painful, any pressure on the atlas region caused intense pain, as also any movement of the head This state of things continued for eight days and then gradually subsided to complete disappearance of all local symptoms in this region by the end of six weeks Hnatek says that the whole trouble was thus shown to be merely a gouty attack, localizing at this point The woman took antineuralgics and electric treatment, the high frequency current Gout, syphilis and articular rheumatism hence must be excluded before we label a case as Rust's disease

81 **Gastro-Intestinal Disease and Fitness for Military Service**—Schuller has been impressed by the rarity of nervous dyspepsia among the troops on active service Even those previously subject to it seem to feel well and stand the conditions on the firing line as well as others Excessive gastric secretion does not impair military efficiency if an ulcer can be positively excluded He has found anacidity much more common than in peace, as also gastric ulcer active or healed A number of men with gastro-enterostomy have gone through the campaign as efficiently as others He has examined about a hundred

82 **Venesection Plus Autoserotherapy**—The first part of Spiethoff's article was reviewed in these columns, January 27, p 310, abstr 44 He here presents data which confirm that robust persons show no permanent consequences contraindicating rapidly repeated venesection One robust young woman with eczema but otherwise healthy, had a red blood count that ranged from 4,136,000 to 4,872 000 with 80 per cent hemoglobin in the course of the third day, after withdrawal of 100 c c blood seven times within thirteen days The white count was 12 000 at first and 9,200 at the last For less robust persons, not over 30 or 50 c c of blood should be removed On the whole the effect seems to be a modification of the general organism or of certain parts of it This is most evident when drugs and other measures, which had lost all power to induce a reaction on the part of the tissues, reacquired therapeutic efficiency after reinjection of the patient's own serum or injection of sodium nucleinate The benefit from venesection and the reinjection of serum is best explained by stimulation of the production of antibodies and their mobilization

84 **The Water Test Meal**—Brendle remarks that the difficulty in obtaining white bread and tea for the Ewald test meal has led to the adoption at the Freiburg policlinic of Austin's water test meal in testing stomach functional capacity In 150 cases the parallel findings with the Austin and Ewald test breakfasts were compared in five sets of tests The findings confirmed that a single water test breakfast according to Austin is sufficient for determination of the chemistry of the stomach Nervous inhibition, with achylic findings, is more liable to be induced with the Austin than the Ewald-Boas technic But this can be warded off more or less completely by addition of raspberry juice to render the test breakfast more palatable, and giving the patient something to chew on and swallow, such as a malt bonbon It is a great advantage of the Austin method that bile, blood, relics of food, etc, in the stomach content show up much better, and further tests, like Salomon's test for albumin, can be more easily applied Brendle uses 100 c c of water plus two tablespoonfuls of raspberry juice The malt bonbon is calculated at 10 gm

90 **Improvement Under Dietetic Measures in Addison's Disease**—Grote reports a case of severe primary Addison's disease the young man lying apathetic in bed No benefit was apparent under suprarenal treatment until efforts were made to increase the sugar content of the blood by feeding extra sugar Rapid improvement followed, the appetite increased he gained in weight, and by the end of eight weeks could walk for an hour without special fatigue, and the pigmentation retrogressed Grote cites evidence to show that the sugar content of the blood has been found abnormally low in two thirds of the cases of pronounced Addison's disease examined to date At the same time the tolerance for sugar is exceptionally good In his case there was no elimination of sugar in the urine after 100 gm of levulose or 200 gm grape sugar At the beginning of treatment the sugar content of the blood was 0 05 per cent , in two weeks after 100 gm sugar had been added to the daily ration—which already included 300 gm carbohydrates—the sugar content of the blood rose to 0 056 per cent , in eight weeks it was 0 1 per cent and the ninth week 0 9 per cent, the rise constantly and closely paralleling the clinical improvement The blood was examined mornings before breakfast Arnoldi recently announced that carbonated baths seemed to stimulate suprarenal functioning, as he found the sugar content of the blood higher after such baths—an "asphyxia hyperglycemia ' Grote consequently gave his patient carbonated baths in addition to the dietetic measures and the organotherapy The literature bearing on the various questions involved in treatment of Addison's disease is discussed in detail

92 **Symptoms of Patent Ductus Arteriosus**—The two patients were girls of 10 and 17, both with curvature of the spine, and the older girl had never menstruated In both during prolonged inspiration and the Valsalva test the systolic murmur dwindled or disappeared entirely, while the Roentgen shadow showed a flattening of the second arc of the heart s left outline—all demonstrating a reduction in the

pressure in the aorta under the influence of the increased alveolar pressure

95 **"Five-Day Fever"**—Sachs reports nine cases and declares that this name for the disease is absurd, as there is no such regularity in the recrudescences of the fever The term "Wolhynic fever" is also irrational as the disease is not restricted to Wolhynia He suggests as the most descriptive term tibialgic or neuralgic fever

102 **Wassermann Reaction Positive in Typhus**—Bittorf some time ago called attention to the appearance of positive Wassermann findings in nonsyphilitics after injury or destruction of organs particularly rich in lipoids, as with cancer of the liver and tumors in the brain or spinal cord As these organs are especially involved in typhus, the blood in this disease likewise responded positively to the Wassermann test in the two cases he has examined for the purpose There was nothing to suggest syphilis in either case, and the response was repeatedly negative when tested from six to nearly eight weeks later

113 Vasomotor Paralysis and Allied Groups of Symptoms in Soldiers on Active Service (Nervose Kriegsdienstschadigungen I) O Gross—p 1577

106 **Reliability of Weil-Felix Reaction**—Cancik writes from Prague that the Weil-Felix test gave positive findings in 90 per cent of his cases of typhus in a recent epidemic In many cases the titer rose from low to high during the course of the disease, while the findings were negative in other patients and in the healthy, or only faintly positive at 1 25 They were constantly negative in forty typhoid cases On the other hand, the Widal reaction sometimes grew more pronounced in typhus patients who had had typhoid at some time or been vaccinated against it (The Weil-Felix reaction was described in The Journal, Jan 6, 1917, p 55)

107 **Roentgen Picture of Certain Form of Chronic Gastritis** —Schwarz calls attention to the indented outline of the entire greater curvature of the stomach in a man of 35 who for years had suffered occasionally from severe gastric disturbances for which no cause could be detected The prominences and inlets shown in the Roentgen picture were most pronounced in the lower part of the greater curvature outline, some of the indentations here being from 1 5 to 2 5 cm deep, but they could be traced almost up to the cardia The peristaltic waves did not modify this outline The laparotomy showed the stomach apparently normal, with no external signs of an ulcer or tumor, but two minute healed ulcers were found in the duodenum, and gastro-enterostomy was done The mucosa of the inner wall of the stomach was found swollen and hyperemic thrown up into numerous thick folds which projected into the lumen of the stomach thus explaining the indented line of the shadow During the three years since this operation, Schwarz has encountered a number of similar cases, although none so extreme as the first Dietlen described an analogous case in 1912, but he interpreted it as inoperable malignant disease, and was surprised to find the patient much improved by the end of a year without special treatment He then assumed that perigastritic changes must have been responsible for the indented outline. Handek described the indentations to traction from an assumed ulcer on the lesser curvature Lengthwise folds in the stomach mucosa may be regarded as physiologic Horizontal folds are evidence of a chronic gastritic process, probably induced by irritation from primary hyperacidity and hypersecretion The conditions thus favor production of an ulcer, which may or may not be present with this "corrugating gastritis"

108 **Electric Palpation of the Abdomen**—Kahane expatiates on the instructive findings with what he calls galvanopalpation of the abdomen With a rheostat and galvanometer he seeks to determine the sensitiveness to a very weak galvanic current He says that an electrode tapering to a point, connected with a 1 milliampere current, can be passed over normal tissues without their feeling it, but it irritates diseased tissues They smart or burn under this galvanopalpation while the vessels dilate, the skin growing red in the area tested He applies the point of the electrode by repeated tapping over a small area The reaction weakens if the test is applied too long in one area The area of the smarting or burning response to the electric current does not always coincide with the location of spontaneous pains or tenderness but the vascular reaction accompanying it confirms the reliability of the information thus derived For instance, if there is pain in the right iliac fossa but negative galvanopalpation findings while there is a pronounced response to the galvanopalpation in the gallbladder region, the probabilities are in favor of the latter s being the source of the trouble Another advantage of the galvanopalpation is that the light touch of the electrode does not injure even acutely inflamed tissues below, when the palpating finger elicits severe pain Among the points learned in the course of Kahane's experience with this electric examination of the abdomen, he mentions the constant positive findings in the right iliac fossa with spastic constipation, and in the left iliac fossa with atonic constipation In a case of pathologic exaggeration of the gastroduodenal reflex with diarrhea directly after eating galvanopalpation revealed a hypersensitive area at the junction of the pylorus and duodenum All other methods of examination gave a negative response Nothing else will locate with such precision the pathologic area as this galvanopalpation, he reiterates, urging others to apply it just before operations and compare the findings with both In the gastric crises of tabes, the stomach region gives negative findings, while positive findings are the rule in the region of the lower dorsal nerve roots With one patient with attacks resembling tabetic gastric crises but for which hysteria and enteroptosis proved to be responsible no positive galvanopalpation findings could be elicited anywhere Of course the reaction indicates merely irritation of the nerve terminals in the skin, but experience has demonstrated that this irritability of the nerve terminals corresponds to a pathologic process below

109 **Eosinophilia After Antityphoid Vaccination**—Draga rejects Labor's conclusions as to the eosinophilia he found in men who had been vaccinated against typhoid Draga has found this eosinophil leukocytosis extremely frequent among his hospital patients, both military and civilian, representing different Balkan nations, and a few had been vaccinated against typhoid He scarcely ever found helminths in the stools, but the necropsies revealed an astonishing prevalence of helminths in the body He declares that nothing short of necropsy justifies an assertion of freedom from helminths

111 **Syphilitic Aortitis**—The preceding instalments of Korczynski s article were reviewed in these columns, page 233 He notes that the location of the mesaortitis seems to be of more moment than its extent Even when the coronary vessels are suffering, this may be due directly to the syphilitic virus, without actual irreparable organic changes Hence energetic treatment of the syphilis may induce wonderful improvement even when the patient seems doomed He insists on repeating the course of treatment if the Wassermann reaction is still positive at its close

118 **Treatment of Ulcerating Granuloma**—In Da Matta's patient the granuloma had persisted for eight months It was in the genital region and measured 3 by 5 cm , a smaller ulcer had developed opposite on the thigh It had only been aggravated by local measures, but marked improvement was noted after the third intravenous injection of tartrate of antimony and potassium, according to the usual technic, and both ulcers soon healed over Eighteen injections were given in all in the course of thirty-four days

119 **Evolution of the Schistosomum Mansoni**—Lutz reports considerable research on this schistosomum, the results confirming Leiper s statements He found that the larvae could hatch out from the ova many days after they had been expelled in the feces Contact with water is required for the ova to hatch and the larvae prefer to stay on the surface of the water These three facts facilitate contagion He experimented with five species of fresh water snails, striving to infect them with the schistosomum but was able to succeed only with one species the *Planorbis olivaceus Spir*, which is encountered mostly in northern Brazil Infection occurs by way of the antennae, the changes in which show when infection is installed Other flat and long snails attract the larvae and they invade the antennae but the evolution of the schistosomum does not proceed to completion in either of them The *Schistosomum mansoni* requires heat for its development its growth and proliferation being impeded or checked entirely by low temperatures

THE AFTER-CARE OF POLIOMYELITIS AS A PUBLIC PROBLEM

ROBERT W LOVETT, M D
BOSTON

No recent event in medicine has caused more anxiety than the epidemic of poliomyelitis during the summer of 1916, which became a panic in certain localities Moreover, the history of the 1907 epidemic and similar records give reason to fear extensive recurrences of the disease during the next two years

While the subject of prevention is one of great importance and public interest, what now demands serious consideration is the care of the wreckage left after the epidemic It is this problem that I desire to discuss I shall speak (1) of the extent of recent epidemics, (2) of the inadequacy of the ordinary facilities for providing the requisite care, and (3) of plans suggested for meeting the existing needs

During the past summer there were reported to the health authorities in the United States no less than 27,000 cases of poliomyelitis About one half of these occurred in the state of New York The other states in which the epidemic was most severe, in the order of the greatest relative prevalence, were New Jersey, Connecticut, Massachusetts, Minnesota, Delaware, Rhode Island and Pennsylvania In only four states — Nevada, New Mexico, Georgia and California — were no cases reported

An official analysis[1] of the New York City cases was made in October This showed that the fatality had been about 26 per cent Of 2,715 patients who recovered and were investigated at their homes, 65 per cent showed a "serious paralysis of one or both lower limbs" and were "unable to walk," and 19 per cent more "were partially paralyzed in the lower limbs, although still able to walk" These figures from New York City give a scale by which one may measure the whole group in a general way, for the figures will probably not differ materially wherever they may be taken

It need hardly be said that no such prevalence of the disease has ever been recorded, and that the statement occasionally heard that there has not been much more poliomyelitis than usual this year and that it is really a newspaper sensation is wholly misleading It is obvious that these thousands of paralyzed children constitute a humanitarian and economic problem of no mean dimensions — a problem which must be defined a little before we proceed farther

Poliomyelitis leaves behind it, in many cases, a paralysis which is of itself disabling, and which, if neglected or badly treated, often leads to serious and disabling deformities These deformities are preventable, with the exception of those affecting the spine and shoulder, by treatment In carrying out this treatment we are striving to prevent deformity and disability, which necessitates a struggle lasting over years Muscles in most instances are weakened rather than totally paralyzed, and the fate of many of them depends on whether in the first year they are protected from fatigue and stretching, and are carefully exercised, massaged and, if need be, supported, under which favorable conditions they may recover, or whether the children are allowed to go about as they will, without efforts to develop muscular strength and without careful therapeutic supervision, in which case the muscles are not likely to recover, and deformities are liable to result

If a modern industrial enterprise had to meet the problem of treating these children properly now or carrying them through life as dependents, there would be no doubt about the financial and economic aspect of the matter, and prompt care would be provided

The dangerous time in infantile paralysis from an economic point of view is not in the first two or three months after the attack That period has its dangers, but in the only three states of which I have first hand information — Vermont, New York and Massachusetts — the disease in this period is efficiently and carefully treated by the general practitioner In 1,700 cases of this year's epidemic recently seen in New York state there have been very few cases in which any preventable deformity, even a dropped foot, had occurred, and not one case in which was found evidence of neglect on the part of the attending physician

At the end of from three to six months, however, there begins a period which lasts for years, during which time many a patient acquires needless, lasting and perhaps disabling deformity As an instance of this, at one of the recent New York clinics among forty patients there were three who will illustrate this point One was a little girl, affected three years previously, whose parents were poor, but who had spent a great deal of money on irresponsible fakers She had acquired a badly overextended knee and could barely walk The condition can be remedied by a brace costing about $5 Two boys had been quadrupeds for nine and seven years, respectively They walked on all fours like monkeys One went to school and went about the class room in this way, they could go up and down stairs and about the house, but always as quadrupeds One needs a pair of braces, a corset and crutches to walk like a human being, at a cost of not over $25 The other needs a preliminary division of some shortened muscles, which will keep him in bed about six weeks, after which, with the apparatus mentioned for the other boy, he can go about

---

[1] New York City Bulletin of Health Oct 23 1916

With regard to the general problem, two states — New York and Massachusetts — have answered that in their opinion the situation requires special measures To these should be added a third and pioneer state — Vermont — which decided in 1914 that an epidemic of about 300 cases was severe enough to warrant state care and supervision, which has been in effect there since January, 1915

The state-wide care of this disease is new, but in Vermont it has seemed efficient It has perfectly clear reasons for its adoption, just as there are certain objections to it which can easily be formulated

The conditions to be met in rural communities and in the small cities, in which there are few, if any, dispensaries, no orthopedic workshops, special hospitals or clinics, are different from those in the large cities, in many of which all of these things are available The question, therefore, will be discussed from both of these standpoints

RURAL COMMUNITIES

A case occurs in a rural community, or in one of the smaller cities It is well and efficiently cared for by the family physician for from three to six months, but the child remains paralyzed If the parents are rich, the child can be sent to the city and obtain the advice and treatment of a specialist But if they are poor, what can the physician do? He has carried the case through the early dangers, he has so far prevented deformities, and he is now faced with the necessity of formulating the future treatment of the case He can send to the city and order apparatus, but it may not fit, and he must leave the design largely to the instrument maker The physician cannot furnish massage or muscle training because there are no experts available, and often he decides to settle down to the routine use of electricity in the hope that it may do some good and because nothing else seems available Finally he and the patient may drift apart, and the latter either does nothing or seeks the aid of fakers who take his money and give him nothing worthy of the name of treatment This happens again and again in rural and suburban communities, less often in the cities, and the family physicians deplore the situation as much as any one

As a result of this situation, deformities, sometimes of the most disabling type, may occur, the patients may become bedridden and distorted, being no longer wage earners, many of them become a burden on the family or on the state Apart from any humanitarian aspect, it is an economic blunder to let this happen on a large scale

IN LARGE CITIES

Take next the paralyzed child in the large cities which are adequately equipped with special hospitals and dispensaries How is he likely to fare? The modern treatment of the after-results of poliomyelitis does not consist in putting on a brace and telling the parents to let the child walk as much as he can and to return when the brace is worn out or no longer fits The dispensaries are quite adequate to carry out this sort of treatment on a large scale, but this does not meet the situation, and the time has come when we should do better

Certain patients are so lightly affected that they will recover, no matter how inefficient the treatment Others are so extensively paralyzed that no treatment will have any great remedial effect, but in the bulk of cases in my experience the ultimate function is greatly influenced by the character, efficiency and continuity of the treatment in the first two years If the patient is to benefit from careful modern treatment at the dispensary, he must report regularly and continuously First comes the question of carfare, often a burden to poor families This expense may be avoided by providing ambulances to carry children to and fro, but the number of ambulances required to cover adequately New York City, for instance, in the present emergency would be very great Second, the time consumed in the trips is a tax on the mothers of large families It is difficult, therefore, for these and other reasons to secure long continued and regular attendance at dispensaries At first the patient is taken to the dispensary with more or less regularity, and receives good or bad treatment, according to the dispensary which he attends But whether the treatment is good, average or poor, the progress of the recovery from the paralysis is in most cases slower than the parents desire and expect, and in time many of them drift away seeking other dispensaries The unintelligent ones turn to the fakers, and others become discouraged and abandon treatment, making up their minds to accept the paralysis as a misfortune which is beyond remedy In this way many become hopeless cripples quite unnecessarily An adequate follow-up system is a help in minimizing this condition Dispensary attendance to be of therapeutic value must go on week by week, month by month and year by year if satisfactory results are to be obtained

Again, in epidemic centers the special dispensaries will in the months following the epidemic be greatly overcrowed, a condition which will inevitably lessen their efficiency Adequate treatment demands a thorough examination, and in each case of poliomyelitis a correct muscular diagnosis can be made only by an examination of each accessible muscle or muscle group in both arms, both legs, back, abdomen and neck This takes time and care as well as experience and skill

Continued residence in a hospital has been advocated by some persons, but such residence to be effective must go on for two or three years in order to cover the dangerous period The objections are obvious (1) Few parents would consent, (2) an enormous number of beds would be required and would be taken from patients with acute cases, (3) the scheme is expensive, and (4) such radical measures are wholly unnecessary

Having thus presented the disadvantages of the dispensary and hospital solution, I turn to that solution which seems to me to be the most satisfactory and most generally applicable both to urban and rural communities, namely, the home care of the patient

The practical aspect of this question — the question of how to meet the problem in a rural community — was presented to me in a concrete form in Vermont in 1915 I had been requested by the Vermont State Board of Health to undertake the after-treatment of about 300 patients paralyzed in the summer of 1914 These patients were scattered through the northern half of the state, many of them living in the country on farms and in the mountains There were no special hospitals or clinics in the state, and the only available means of dealing with the cases seemed to be to assemble the patients at clinics in five centers At these clinics each patient was thoroughly examined by me, with the aid of one muscle trainer, in consultation with the attending physician, who was generally present If apparatus was needed, it was measured for by me, made under my direction and sent to the physician If muscular exercises were needed, they were formulated at the time of the examination, and the mother was taught to give them and received written instructions describing them The family and the physician were warned of the bad effect of fatigue, and the whole situation was discussed and emphasized before the patient left the clinic The usual arrangement was that the mother or father was to give the exercises, and the physician was to supervise the treatment After these clinics no attempt was made to hurry, and the patient received quite as much time and attention as in private practice If the family physician was not present, a letter was written to him describing the case and the treatment advised, and in every case a copy of the record was sent to him If apparatus was necessary and the parents were too poor to pay for it, it was partly or wholly paid for out of a fund at the disposal of the state board of health If operation was necessary, it was arranged for at a local hospital or elsewhere No follow-up nursing care was attempted at this time, because no one sufficiently skilled in muscle training was available. There the plan rested, and no further clinics were held until July, 1915, six months after the first series, when I went to the same places and held a second series of clinics The results were surprisingly good, and to my astonishment seemed on the whole better than results from routine dispensary treatment The crude plan worked out to meet a special emergency had succeeded

At this time a woman skilled in muscle training was secured and left in Vermont for the summer, visited it at intervals during the winter, and lived there during the summer of 1916 She made rounds of the centers, visited the parents, encouraged the mothers and kept them up to their work, talked with the physicians, reported delinquents and defects in apparatus, kept patients away from the quacks and charlatans, and changed exercises when necessary Although highly efficient and working to the limit of her strength, she could not keep track of all the cases, and a resident qualified assistant is now to be employed

As a result of this work in Vermont, directed by the board of health, many children have been prevented from becoming cripples and from acquiring needless and often disabling deformities, the families have become intelligently interested in the treatment, and the physicians have without exception cooperated, and have become interested in the after-care, as a result of which, I believe, they have become better equipped to treat these cases than most general practitioners in the large cities

A third series of clinics was held in July, 1916, from which certain data were obtained, which have been published,[2] and it is the purpose of the board of health to continue as long as necessary the supervision and treatment of these patients

Such is an account of a pioneer attempt to carry out state care of poliomyelitis patients on a simple scale

In the autumn of 1916, the state department of health of New York decided to undertake the treatment of the cases in New York State outside of New York City, following the Vermont plan, and I was asked to inaugurate and supervise the work, which began, Oct 17, 1916, at White Plains

Clinics are given at centers selected according to the grouping of the cases, and four clinics each week are held Associated in the work are Dr Armitage Whitman of New York and Dr John T Hodgen of Boston Under them are several highly skilled nurses who have been taught muscle training, and two crews of two women each, experts in spring balance muscle testing, because quantitative studies are deemed a most important part of the work

To follow up the after-treatment of the cases, nurses who are skilled in muscle training are left behind, one in a district, to work under the physicians and see that the treatment prescribed is followed, that exercises are done as ordered, that such exercises are modified as need arises, that apparatus is worn, that fatigue is avoided, and that patients report at subsequent clinics

To replace these nurses who are dropped in the districts, new nurses are taken on to travel in the unit, there to be educated in muscle training and in their turn left behind in a district As soon as the first round of clinics is completed, which will have taken nearly three months, a second series of clinics will be held in the same places, and the treatment will be modified as necessary Such a scheme to be productive of the best results cannot be finished in one year, but must go on for two or three years, and possibly for a longer time

In Massachusetts, where the epidemic started later than in New York, the Harvard Poliomyelitis Commission was requested by the state department of health to assume the responsibility of the after-care of the cases of paralysis in the state, and in November, 1916, undertook this in addition to the purpose for which it had been originally appointed, namely, to aid in the diagnosis and treatment of the acute stage and to undertake the study of the etiology of the affection

Here the Vermont plan, in a somewhat modified form, is again being followed The Children's Hospital, by the generosity of an anonymous donor, has been enabled to open a special clinic for the treatment of poliomyelitis, which has been designated as the central clinic of the commission, with which certain other clinics cooperate This is intended to serve the area within 20 miles of Boston For the other parts of the state, clinics will be held at different centers, following the same plan as in Vermont and New York

New York City has appointed a committee on the after-care of poliomyelitis, and various other municipalities have inaugurated public clinics The state of Minnesota also is considering a campaign of a similar sort

The essentials for state or city care are

1 A traveling or stationary unit headed by one or more surgeons, which may be taken to the affected centers where free public clinics are held The visiting surgeon acts as consultant to the family physician and deals with the cases through him

2 Sufficient time given to each clinic to secure adequate and thorough examination, and careful formulation of treatment by the surgeon and skilled assistants

3 Follow-up care in the homes by highly skilled women, who supervise the muscular exercises, encourage the families, see that the family physician's instructions are followed, and that the patients are kept from falling into the hands of charlatans

[2] Lovett R W and Martin E G Certain Aspects of Infantile Paralysis, with a Description of a Method of Muscle Testing, The Journal A M A, March 4 1916 p 729

weeks, after which, with the apparatus mentioned for the other boy, he can go about

With regard to the general problem, two states — New York and Massachusetts — have answered that in their opinion the situation requires special measures To these should be added a third and pioneer state — Vermont — which decided in 1914 that an epidemic of about 300 cases was severe enough to warrant state care and supervision, which has been in effect there since January, 1915

The state-wide care of this disease is new, but in Vermont it has seemed efficient It has perfectly clear reasons for its adoption, just as there are certain objections to it which can easily be formulated

The conditions to be met in rural communities and in the small cities, in which there are few, if any, dispensaries, no orthopedic workshops, special hospitals or clinics, are different from those in the large cities, in many of which all of these things are available The question, therefore, will be discussed from both of these standpoints

RURAL COMMUNITIES

A case occurs in a rural community, or in one of the smaller cities It is well and efficiently cared for by the family physician for from three to six months, but the child remains paralyzed If the parents are rich, the child can be sent to the city and obtain the advice and treatment of a specialist But if they are poor, what can the physician do? He has carried the case through the early dangers, he has so far prevented deformities, and he is now faced with the necessity of formulating the future treatment of the case He can send to the city and order apparatus, but it may not fit, and he must leave the design largely to the instrument maker The physician cannot furnish massage or muscle training because there are no experts available, and often he decides to settle down to the routine use of electricity in the hope that it may do some good and because nothing else seems available Finally he and the patient may drift apart, and the latter either does nothing or seeks the aid of fakers who take his money and give him nothing worthy of the name of treatment This happens again and again in rural and suburban communities, less often in the cities, and the family physicians deplore the situation as much as any one

As a result of this situation, deformities, sometimes of the most disabling type, may occur, the patients may become bedridden and distorted, being no longer wage earners, many of them become a burden on the family or on the state Apart from any humanitarian aspect, it is an economic blunder to let this happen on a large scale

IN LARGE CITIES

Take next the paralyzed child in the large cities which are adequately equipped with special hospitals and dispensaries How is he likely to fare? The modern treatment of the after-results of poliomyelitis does not consist in putting on a brace and telling the parents to let the child walk as much as he can and to return when the brace is worn out or no longer fits The dispensaries are quite adequate to carry out this sort of treatment on a large scale, but this does not meet the situation, and the time has come when we should do better

Certain patients are so lightly affected that they will recover, no matter how inefficient the treatment Others are so extensively paralyzed that no treatment will have any great remedial effect, but in the bulk of cases in my experience the ultimate function is greatly influenced by the character, efficiency and continuity of the treatment in the first two years If the patient is to benefit from careful modern treatment at the dispensary, he must report regularly and continuously First comes the question of carfare, often a burden to poor families This expense may be avoided by providing ambulances to carry children to and fro, but the number of ambulances required to cover adequately New York City, for instance, in the present emergency would be very great Second, the time consumed in the trips is a tax on the mothers of large families It is difficult, therefore, for these and other reasons to secure long continued and regular attendance at dispensaries At first the patient is taken to the dispensary with more or less regularity, and receives good or bad treatment, according to the dispensary which he attends But whether the treatment is good, average or poor, the progress of the recovery from the paralysis is in most cases slower than the parents desire and expect, and in time many of them drift away seeking other dispensaries The unintelligent ones turn to the fakers, and others become discouraged and abandon treatment, making up their minds to accept the paralysis as a misfortune which is beyond remedy In this way many become hopeless cripples quite unnecessarily An adequate follow-up system is a help in minimizing this condition Dispensary attendance to be of therapeutic value must go on week by week, month by month and year by year if satisfactory results are to be obtained

Again, in epidemic centers the special dispensaries will in the months following the epidemic be greatly overcrowed, a condition which will inevitably lessen their efficiency Adequate treatment demands a thorough examination, and in each case of poliomyelitis a correct muscular diagnosis can be made only by an examination of each accessible muscle or muscle group in both arms, both legs, back, abdomen and neck This takes time and care as well as experience and skill

Continued residence in a hospital has been advocated by some persons, but such residence to be effective must go on for two or three years in order to cover the dangerous period The objections are obvious (1) Few parents would consent, (2) an enormous number of beds would be required and would be taken from patients with acute cases, (3) the scheme is expensive, and (4) such radical measures are wholly unnecessary

Having thus presented the disadvantages of the dispensary and hospital solution, I turn to that solution which seems to me to be the most satisfactory and most generally applicable both to urban and rural communities, namely, the home care of the patient

The practical aspect of this question — the question of how to meet the problem in a rural community — was presented to me in a concrete form in Vermont in 1915 I had been requested by the Vermont State Board of Health to undertake the after-treatment of about 300 patients paralyzed in the summer of 1914 These patients were scattered through the northern half of the state, many of them living in the country on farms and in the mountains There were no special hospitals or clinics in the state, and the only available means of dealing with the cases seemed to be to assemble the patients at clinics in five centers At these clinics each patient was thoroughly examined by me, with the aid of one muscle trainer, in consultation with the attending physician, who was generally

Payne,[9] Fletcher,[10] Beebe,[11] Best,[12] Williams,[13] Logan,[14] and Leary[15] The results of their investigations were diverse and do not materially assist in clearing up the confusion existing relative to the bacteriology of the disease The only deduction which they justify is that a number of microorganisms, potentially pathogenic, may under certain conditions be isolated from suppurative lesions of the gums

The possibility of spirochetes being concerned pathologically in pyorrhea has received some attention Various workers, including Noguchi, have described spirochetal types found in the oral cavity, and in 1912 Noguchi[16] isolated, in pure culture, from a case of pyorrhea a mucin producing spirochete which he named *Treponema mucosum* This organism is not regarded by Noguchi as strictly parasitic, but he ascribed to it pyogenous action under conditions in which the tissues have been so injured as to enable it to survive The strong fetid odor in some cases of pyorrhea he believes to be due in part at least to the presence of *T mucosum*

Recent bacterial studies which seem to be entitled to careful consideration are those reported by Medalia,[17] Brown,[18] and Hartzell[19]

Medalia's reports were based on a study of 115 cases, in which a careful bacteriologic investigation appears to have been carried out The series included fourteen incipient, sixteen moderately advanced, and eighty-five advanced cases The findings reported are as given in Table 2

We would be led to infer from these results that the pneumococcus is the most important organism to be considered, as it was found either alone or in combination in 107 of the 115 cases (93 per cent), and the streptococcus only an occasional invader, as it was reported as being present in only fourteen cases (12 per cent) The work of other investigators does not, however, substantiate this deduction Brown in forty-eight cases observed *Streptococcus viridans* twenty-three times, hemolytic streptococci thirty times, and nonhemolytic streptococci twenty-eight times Pneumococci were present in twenty-seven cases, staphylococci, diphtheroids and organisms of the *Bacterium influenzae* group being also frequently found

Hartzell's work, perhaps the most convincing of any that has been reported, points strongly to the importance of the streptococcus in pyorrhea His observations have indicated that approximately three fourths of the bacterial content of pyorrhea pus pockets is made up of pyogenic cocci of the *Streptococcus viridans*, and staphylococcus types, and the remaining one fourth of other organisms Hartzell's animal inoculations have shown that following the intravenous injection of pus from pyorrhea pockets streptococci of the viridans type are usually recovered, occasionally staphylococci

Personal observations relative to the occurrence of streptococci, staphylococci and pneumococci in pyorrhea would place streptococci first in frequency, staphylococcus next, pneumococci being observed in only a small percentage of cases

The scope of this paper does not extend to a consideration of the relationship existing between pyorrhea and systemic diseases The importance of oral infection in metastatic infections of the heart, blood vessels, joints, kidneys and other tissues is, however, generally recognized Hartzell has emphasized the fact that of the organisms found in the mouth, there are none having the varied possibilities for disease production characteristic of the streptococcus group Clinical observations as well as the results of animal inoculations have clearly shown that in the remote pathologic effects of oral infection, the streptococcus overshadows in importance all other organisms which may be present in pyorrhea pockets

A discussion of the causative factors in pyorrhea necessarily involves a consideration also of its pathology Considering interstitial gingivitis and pyorrhea alveolaris as phases of the same disease, we generally recognize that bacterial invasion is characteristic of the pus stage and is not necessarily present in cases of interstitial inflammation without pus The bacterial studies which have been reported are based largely on investigation of cases of the purulent type The occurrence of gingival inflammation, without infection, as the result of trauma, irritation and constitutional influences during the nonpurulent inflammatory stage of the disease is scarcely open to question On the other hand, the conclusion of some investigators that bacterial invasion in pyorrhea is invariably a secondary factor, infection being universally absent prior to the pustular stage of the disease, does not seem to be established An infected zone around the root of the tooth, usually due to acute streptococci infection, may exist It would be strange indeed if this were not so, since the poorly protected gingival crevice offers a splendid opportunity for bacterial attack, the microbic penetration being aided by the formation of calculi on the roots of the teeth or at the gingival margin and

4 Subsequent clinics held in the same place at intervals of three months or more over a period of at least two or three years

5 A copy of each record filed with the state department of health or central directing committee

The advantages of the plan are Special advice and treatment become available to all patients, the families are enlisted in the care of their children and share the responsibility, the family physician is assisted and not superseded, skilled assistance in after-care is provided over an indefinite time by those specially trained, the patients are kept under supervision, the clinics are educational to the profession, and the expense is not excessive

The objections to the plan are Like all schemes of state care it savors of paternalism, it is difficult to convince the community and the profession that such elaborate and long continued measures are really necessary, it has long been the custom to regard infantile paralysis as a chronic affection, on the whole hopeless, best treated by braces, with perhaps massage and exercises which any nurse or masseuse can give One of the most serious obstacles to the scheme is the difficulty of making it understood that muscle training in poliomyelitis is a delicate and serious matter requiring much skill and experience A simple explanation will show this A child is left with certain muscles in a limb normal and many weakened If exercises of an inaccurate character are given, the child inevitably uses the strong and not the affected muscles, and the strong muscles become overdeveloped and the weak ones are not used, so that the resulting condition is worse than if nothing had been done Loosely given muscular exercises are dangerous and harmful The person directing the exercises must know enough functional anatomy to prescribe such as will exercise only the weak muscles, a task far beyond the ordinary masseuse or nurse who has not had special training

The question of how far the financial burden should fall on the state and how far on private individuals is a delicate one, but as a matter of record most similar new enterprises of state-wide importance in America have first been partly or wholly cared for by private benefactions This is not the time to hesitate about a theoretical matter of this sort Any plan will require expenditure of money, and to be adequate must be formulated and put into effect promptly in the most seriously affected communities, consequently, private funds must be employed Since delay means disability, deformity and incapacity to so large a number of children, no affected community is likely to hold back long if a satisfactory plan for relief is presented

One danger deserves comment, namely, indiscriminate giving to independent enterprises not correlated to the main one A sound plan is the first essential, administered by the state or city or capable private interests, and to this plan should be tributary and related special funds

SUMMARY

I have tried to show that the number of paralyzed children among us demands an increase in our existing facilities for relief, that the problem affects both rural and urban communities, that dispensary treatment and hospital residence have defects, that state or city care offers a more satisfactory solution and has proved efficient in Vermont, that the Vermont plan is being tried in other states, and that to be successful the plan must have related and subordinated to it independent organizations for relief

BACTERIAL FINDINGS AND THEIR RELATIONSHIP TO PYORRHEA ALVEOLARIS AND INTERSTITIAL GINGIVITIS *

A W LESCOHIER, M D
DETROIT

Few subjects in medical history have given rise to more frequent controversies than the inflammatory diseases of the gums The classification, nomenclature, pathology, even the anatomy of the parts involved have afforded material for protracted argument Probably no phase of the subject has been more keenly discussed than the etiology, and during recent years much of this interest has centered on the part played by bacterial invaders

The probable relationship of pathogenic bacteria to the development of pyorrhea has been recognized for several decades Mallasez and Galippe[1] (1884), Black[2] (1887), Miller[3] (1889) and Kirk[4] (1898) were some of the early investigators of its bacteriology A variety of organisms were described, none of which could be specifically associated as the causative factor Probably the first to ascribe etiologic significance to any particular micro-organism was Arkovy[5] (1904), who attributed acute cases of alveolar suppuration to streptococcic infection

A detailed review of the voluminous literature on the bacteriology of pyorrhea and allied conditions appears neither necessary nor desirable Many of the reports were based on studies the scope of which was limited both by the paucity of cases under observation and the facilities and training for their intelligent investigation It seems advisable rather to try to correlate the facts established by those investigators who have definitely contributed to the bacteriology of the disease

Perhaps the most notable of the early studies on the relationship of micro-organisms to the pathology of pyorrheal diseases is that of Goadby[6] His first report in 1907 described a variety of organisms occurring in connection with pyorrhea, to none of which it was possible to attribute a definite etiologic relationship This group of organisms included, in addition to the pyogenic cocci, various types of bacilli and spirilli Curiously enough, in view of later developments and the fact that a study of his protocols shows that streptococci and staphylococci were found much more frequently, Goadby appeared to attach considerable importance to the bacillary forms In 1908 Goadby reported the successful treatment of two acute cases of pyorrhea alveolaris with autogenous vaccines, in one of these the infection was mixed streptococcus and *Staphylococcus albus*, and in the other streptococcus was present almost in pure culture In 1909-1910 a supplementary study of seventy cases was reported, in which the findings are given in Table 1

During the period from 1907 to 1912 articles dealing with the bacteriology of pyorrhea were contributed by numerous workers, among whom may be mentioned Carmalt-Jones and Humphrey,[7] Sims,[8] Eyre and white line extending to and around the apex, together with a slight widening of the space occupied by the peridental membrane itself This finding is the premonitory sign of the inflammation of peridental membrane which precedes extension of the funnel shaped pocket to and around the apex It is now only a matter of a short time till the entire depths of the root are surrounded by the liquefied products of the ulcerative pericementitis

The limitations in the value of the Roentgen findings in any disease should also be mentioned While the Roentgen findings in pyorrhea as a rule agree very well with findings elicited by a digital or instrumental examination, and are obtained with far less discomfort to the patient, there are certain respects in which they are disappointing Let me mention a few of these Sometimes a pyorrhea tooth is quite loose, and a well defined pocket is expected in the roentgenogram Instead, it may require a stretch of the imagination to find in the roentgenogram more than a simple loss of the normal white line This is undoubtedly because the atrophy which has occurred is diffuse and poorly demarcated Again the tooth shows no looseness on examination, and the roentgenogram shows the deepest kind of a pocket This apparent discrepancy is undoubtedly due to the escape from the disease of a limited portion of the investing structures, not recognizable roentgenographically, but sufficient in amount to maintain the stability of the tooth for the time being A very important point in the diagnosis may be entirely undemonstrable by Roentgen methods, and I refer to the activity of the disease at the time of examination Quite frequently roentgenograms are essentially similar in cases in which gross amounts of infective material can be expressed from the jaw to those in which the disease in all its clinical manifestations is entirely quiescent or advancing at a very slow rate It may be sufficient to mention the general roentgenographic fact that in an ulcerative process in which bone shadows show partial or poorly limited decalcification, the process is in an active or rapidly progressive stage, whereas in well demarcated cases, in which areas of complete liquefaction lie directly adjacent to areas of undisturbed bone, the process may be considered more chronic in type

CONCLUSIONS

A general survey of the denture by a series of dental films is an important adjunct to the examination of a pyorrhea case It is often a short cut to a diagnosis and is less disagreeable than an instrumental examination, but should supplement rather than displace other diagnostic methods The most important diagnostic points are observable in the region of the intimate bony investments of the roots and are obtainable only from the most critical roentgenograms

122 South Michigan Avenue

Disposing of Sputum—One of the problems in taking care of tuberculous persons is to dispose of the sputum, according to the *Sanitary Bulletin* of the Buffalo Health Department Sometimes in chronic or advanced cases this amounts to a great deal, and when no furnace fire is available, its safe disposal taxes the ingenuity of the attendants A nurse suggested a plan which is said to be effective and feasible Provide a galvanized pail or garbage can and place in the bottom of it some charcoal Place in this the sputum cups, cover with kerosene and take into the alley or yard and set on fire The charcoal will hold the fire until everything is consumed

---

THE IMPORTANCE OF A CORRECT DIFFERENTIAL DIAGNOSIS OF THE PREDISPOSING CAUSES

IN CASES OF INTERSTITIAL GINGIVITIS OR PYORRHEA ALVEOLARIS *

M L RHEIN, M D, D D S
Lecturer on Dental Pathology Department of Dentistry University of Pennsylvania
NEW YORK

Periodically, we are told that interstitial gingivitis, or pyorrhea alveolaris, is caused by some special organism which the writer has just discovered Specific investigation and attempts to corroborate these vaunted discoveries have always proved them to be erroneous We are just beginning to recover from the shock of how little we know about the *Endameba buccalis* The fact that a prominent research worker in medicine proclaimed to the world that the endameba was responsible for every case of pyorrhea, and that this disease was present in 95 per cent of our population, has been the direct cause of much confusion Physicians lacking education in mouth physiology and pathology were especially imposed on by this dogmatic assertion

Research work which I have conducted in the mouths of animals has corroborated the work of general observers to the effect that infection is impossible in an individual otherwise physically well Considering, as we are, end-organ tissue, it must be admitted that unless prophylactic measures have been adopted, the so-called dental organs are the first to exhibit a diminution in immunity to infection, if any form of malnutrition is in evidence If, by exercise, massage and other hygienic measures, the circulation in the ultimate capillaries is kept moving, the gums and peridental tissue will frequently retain their immunity, even though malnutrition is present

Pyorrhea alveolaris is a result of malnutrition plus infection, and also most frequently plus irritation, and it is greatly intensified if arteriosclerosis of the ultimate capillaries sets in Only daily observation of the dental tissues can make one familiar with the appearance of a normal mouth, and without this knowledge, it appears impossible for any one to differentiate the different appearances of these tissues in different diseases

While all forms of pyorrhea must commence with some form of gingivitis, yet the tissues in this and all succeeding stages vary in clinical appearance as markedly as do the generic types of malnutrition which interfere with a proper equilibrium of the circulation The blue line in the gums as a result of mercurial toxemia, and the mucous patches due to syphilis, are old landmarks in medical diagnosis In like manner the physician awaits the eruptive stage in order to make a correct diagnosis as between smallpox and measles or any of the other exanthems It may, therefore, be asserted with assurance that the variations in clinical appearance of the gums and pericemental tissues point with unerring fidelity to the cause of the dyscrasia When these are once read with the same assurance with which we now read the blue line, a great advance in the diagnosis of this disease will have been reached When it is once duly appreciated that pyorrheal symptoms are a possibility at the very onset of any inter-the number of the infecting organisms being augmented by the neglect of oral hygienic measures

---

* Read before the Section on Stomatology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

The tendency to consider any etiologic factor in pyorrhea as an entity instead of in relationship to other influences is unfortunate Irritation, trauma, metabolic disturbances and microbic invasion constitute a vicious circle in the development of alveolar diseases The bacterial element is probably the most important element in the destructive tissue changes and certainly so in the serious sequelae While it is impossible definitely to classify interstitial gingivitis or even pyorrhea as primarily a microbic disease, the pathology is intimately associated with the results of bacterial invasion and the adequate consideration of its treatment must necessarily recognize the importance of the infectious element

---

THE ROENTGEN RAY IN THE DIAGNOSIS OF PYORRHEA *

HOLLIS E POTTER, M D
CHICAGO

Roentgenography for the demonstration of pyorrhea alveolaris does not differ in its technical plan from that used in other procedures intended to shed light on diseases located in the jaw bones The constant feature of the disease which makes its demonstration by roentgenoscopy possible is the ulceration of the presenting margins of the alveolar process and the more intimate bone about the roots In general the extent to which this marginal bone is found to be eroded is the measure of the extent of the disease recorded on Roentgen-ray films or plates The relative simplicity of a Roentgen-ray procedure which is required to show only the height or depth of a bone profile in so thin an object as the human jaw is quite apparent, and in reality no such rigid technic is necessary in pyorrhea as in the demonstration of periapical disease, in which a focus of minor decalcification must be detected in and surrounded by a considerable mass of bone of variable and often complex structure

This rough delineation of the general present depth of the process with respect to the dental roots in a case of known pyorrhea is therefore a relatively simple problem, and in itself is scarcely deserving of a lengthy dissertation But in any series of pyorrhea cases the general roentgenographic survey is capable of bringing to light some of the minor changes about the roots of individual teeth, such as the localized or beginning extension of the disease toward a given apex, the softening of the adjacent alveolar wall due to an early inflammation of a single peridental membrane—the signs, in short, of the early and deeper encroachments of the disease which are so important in the complete diagnosis and prognosis of a pyorrhea case For the detection of these minor but most important changes in the bony investments of the teeth only the most critical roentgenography is of value, and this must be combined with a careful and intelligent reading

In roentgenograms of the normal denture, the spongy bone of the jaw uniformly envelops the dental roots and proceeds fully up to the point of attachment of the peridental membrane In the most critical roentgenograms, the shadow of this spongy bone is seen through the shadow of the dental root, but is most prominently visible in the septal bone The septal bone is characteristically of triangular shape, with more compact bone at the marginal apex, and at this apex one often sees an apparent fusion of the white line surrounding the adjacent roots This so-called white line is the shadow cast by the denser walls of the alveolus between which and the roots themselves is the slight space occupied by the peridental membrane

It is well known dental pathology that in pyorrhea the primary site of bone liquefaction is in that bone immediately adjacent to the peridental membrane For this reason it is so often seen in roentgenograms that the marginal line of persistent bone is wavy with the deepest erosions in juxtaposition with the teeth Whenever in roentgenograms it is seen that a localized or deeper absorption has occurred, it must be admitted that no correct inference can be made as to whether this erosion lies primarily on the labial, buccal or lingual aspect of the process There is seldom seen in the most critical roentgenograms a double marginal line which could be known to represent, respectively, the inner and outer limits of erosion, and even where the double line is seen, it is impossible to distinguish the inner from the outer Moreover, the film method calls for the projection of the light at such angles that, while the teeth show with minimum distortion, there is a palpable displacement on the film of the position for attachment of the peridental membrane externally with respect to its internal attachment Should, therefore, the double line be visible in every case, a correct interpretation would involve a reasonable discount for angular displacement For this reason, the most accurate and comprehensive portrayal of the exact position and the extent of the erosion is often obtained by the stereoscopic method, in which the stereoscopic shift is made along a vertical line rather than along the usual horizontal line, for reasons apparent to those versed in stereoscopic roentgenography in general To obtain the most valuable average line as a gross measure of the ulcerative process, roentgenograms may be made at a considerably lower angle than for demonstration of the apexes, although an elongation of the dental shadows themselves will result

Whether or not the general line limiting the ulcerative process can be followed across the shadows of the roots themselves, it will usually show plainly in the region of the septal bone Wherever the teeth are normally spaced and the septal bone abundant, the marginal dissolution at the interspaces is very plain In case the teeth are closely crowded and the septal bone small in amount, or when for any cause the ray angle used in the exposure was such that a lateral overlapping of dental shadows has resulted, the depth of septal bone is indeterminate Inasmuch as the septal bone erosion is usually less than that in the immediate vicinity of the peridental membrane, the amount of septal destruction is not to be taken as the true limit of the encroachments of the disease on the jaw Rather, this must be based on a careful observation of the integrity of the bone enveloping the peridental membrane farther toward the apex Often a lateral or circumferential absorption can be followed deeply toward the apex This appearance denotes a localized pyorrhea pocket, and is often concentrically funnel shaped In conjunction with this funnel shaped dissolution, which extends around the tooth to a greater or less depth beyond the line of septal erosion, is often seen a more delicate partial decalcification of the

SOME STUDIES IN THE TREATMENT OF PYORRHEA ALVEOLARIS *

GEORGE BAILEY HARRIS, D.D.S., Sc.M.
DETROIT

In the consideration of the treatment of pyorrhea alveolaris, as with any other disease, we must presuppose a knowledge of the disease. There are, however, so many conditions suggested as being causative factors in pyorrhea, that it is hardly possible to assume that any one of them is responsible for pyorrhea, to the exclusion of the rest. Among the conditions which have been advanced as being causative agents in pyorrhea might be mentioned syphilis, rheumatism, liver affections and autointoxication. These conditions and any other which will lower the resistance of the tissues must be considered as causative factors in pyorrhea, and their eradication, wherever possible, must be accomplished when the treatment of pyorrhea is undertaken.

Pyorrhea should be looked on as an infectious disease and treated as such. Its inception, then, is based on the resistance of the tissues to bacterial invasion, which must be lowered before the infection can be overcome. This means the building up of the resistive forces throughout the entire body, as it is difficult to perceive how the resistance, under these conditions, can be raised in the gum tissues alone. This must be done not only to throw off the present infection but also to guard against its recurrence. The lowered resistance to the tissues surrounding the teeth is due, in many cases, to the well known calcium deposits and irritations produced by faulty dental work. These conditions must be corrected.

If, however, we better understood the causes of pyorrhea and knew more about the tissues most vitally involved in making a repair, we would be able to treat this disease more intelligently, and there would result a greatly increased number of recoveries.

I have been greatly surprised at the wonderful recuperative power of the cementum. The literature relating to this tissue is confined, in the main, to its description and histologic structure, very little being said about its use. Cementum is the bond between the teeth and the bone, the tooth and bone seemingly being unable to form a union themselves. It seems to have about the same recuperative power as bone, and, furthermore, under proper conditions, cementum has the power to regenerate, after it has been cut in grooves or removed entirely from the root, provided a sufficient amount of the cementum is left on the root from which regeneration can take place. If, however, a large portion of the cementum is removed and the remainder then weakened or entirely destroyed by such mild germicides as trichloracetic or sulphuric acid, we should not expect to have any reformation of the cementum. When this is done, we might just as well take the next step at once and extract the tooth as wait and do the same thing at a later date or let nature throw it off herself.

Some time ago I had occasion to make an upper denture for a woman about 50 years old. She had worn full upper and lower dentures for some twenty years. On examining her mouth I noticed an enlarged and inflamed surface in the region of the second bicuspid. She informed me that it had been giving her trouble for a long time and that she had to have a place cut out of the denture to avoid pressure on it. I opened into it and removed about one third of the root of the second bicuspid, which had been broken off when the tooth was extracted. The one side was flattened, but there were no sharp edges. A cross-section was made, and when put under the microscope it was found to be completely encased in cementum, the cementum on the flattened surface being nearly a third thicker than the other. A section made near the apex of the root showed a normal condition, with no variation in the thickness of the cementum. When this root was extracted, instead of breaking off at right angles, it split at an angle, and the cementum remaining not only regenerated sufficient tissue to cover that portion of the root that had been stripped of its cementum, but a third more. Dr. Fletcher has recorded a case in which the crown had been broken off in an attempted extraction, and the cementum had not only grown over the dentin but also had partly filled the canal. In this case, too, the cementum which had grown over the dentin was much thicker than normal. These cases seem to show that we may expect a restoration of tissue to a great extent, if not entirely, provided the conditions governing such a growth are ideal. This means that the new cementum forming must not be removed daily or weekly in the overzealous use of scalers and files, nor must the healthy cementum and paradental membrane be removed. To get something, something must be left. The regeneration of the cementum must be the result of stimulation, brought about by the careful use of the affected teeth, and there must be an active blood supply. This can be encouraged by careful but not too diligent massage, and the absence of astringent mouth washes. The teeth must be cleaned, not merely brushed.

The bacteria commonly found in pyorrhea are constantly present in the mouth. If oral hygiene is a common practice with the individual, their numbers are greatly lessened; if not, they become very abundant. A person can go for years with ill fitting crowns and maintain an ideal condition for the development of pyorrhea. That is resistance, and when it is lowered, pyorrhea follows quickly. As long as he maintains that resistance, he is immune; but as soon as it is lowered, pyorrhea overtakes him. In order to recover, that resistance must be returned; otherwise the pyorrhea will only be kept in check, never cured. To prevent the formation of tartar deposits, after they have been removed, Epsom salt is most proficient. It might be said that constipation plays an important part in the formation of these deposits, and should form a sort of index in cases of chronic constipation.

There are a great many pathologic conditions which have or are supposed to have their origin in mouth infections, of which pyorrhea is a common and important one; but it must be remembered that there are lots of people with arthritis who are wearing full upper and lower dentures and have been so doing long before they become afflicted with arthritis. There are a great many cases of arthritis that have their foci in the mouth, but these infections are sometimes present in cases of arthritis, the removal of which does not result in the disappearance of arthritis to any degree. In these cases, therefore, while there may be pyorrhea and other foci of infections present, and while every effort must be made to eradicate them,

ference with the normal action of any vital function, and that a proper reading of their clinical appearance will disclose at once the nature of the trouble, the study of the dental organs will be properly comprehensible, and not until then

The fact that pyorrheal manifestations are very frequently observed, without the investigator being able to obtain any confirmatory diagnosis of some form of malnutrition, is generally due to the fact that impairment of the vital organs progresses very slowly, and that frequently with our present day methods it is impossible to make a correct diagnosis until the disease has reached an advanced stage

When, finally, as the organic disease increases, a correct diagnosis is made, it is not uncommon to find that this organic disease is believed to be caused by the pyorrhea The poor diagnostic sense of the uninformed dentist is the cause of this frequent error in diagnosis, this placing of the cart before the horse While an abnormality of some important organ or organs of the body is generally the predisposing cause, we see other types of pyorrhea where the predisposing cause is the decrease in functional power of the teeth themselves Here loss of teeth by extraction, irritation under the gingivae from unpolished fillings, and every type of malocclusion become the predisposing causes instead of their being caused by some organic disease

Every dentist will corroborate the great variation in the mouth picture which presents itself in different pyorrheal cases We see the case without any deposit on the root in strong contrast with those in which these deposits seem to overwhelm all the exposed root structure We see the gum abnormally dry and parched in contrast to those cases in which the mucous follicles are constantly excreting varying quantities of fluids There is the pale anemic gum in contrast to the ruby red inflamed gum We find pockets under the gums free from suppuration or exudation, in contrast to those cases in which there are purulent discharges, and the gums are so inflamed and spongy in character as to bleed on the slightest provocation There are cases in which the gingival border is atrophied to a knife blade edge in contrast to every type of hypertrophied tissue The gums at times will be found in all possible shades of color, and in certain cardiac diseases there is a sharp division line between a normal pink and dark blue in the gums in the same mouth

We find no such variation in symptoms in any infectious disease Smallpox, tuberculosis, typhoid fever, measles, syphilis, yellow fever, diphtheria, etc, all possess well defined symptoms, which mark them unmistakably as the disease in question

In interstitial gingivitis or pyorrhea alveolaris, the clinical appearance is but a reflection of the predisposing cause Each different picture will always be found associated with one particular predisposing cause A carefully recorded study of these different pictures will soon make the observant stomatologist familiar with at least some of the more common types of malnutrition, and after a time he can readily recognize them on sight

It has been my good fortune, because of experience with these clinical pictures, to have frequently been the means of directing the patient in the early stages of some serious ailment in keeping with rational treatment It is impossible to estimate too highly the value of such a diagnosis being made in an early stage It is wrong for us to discuss this subject as though we were speaking of some specific disease instead of addressing ourselves to pathologic symptoms of one of many diseases

The time will come, when the subject is under discussion, that it will be confined to the particular malnutrition causing a given type of pyorrhea In 1894, I presented such a method of classification by prefixing or adding an adjective stating the name of the disease, which is causing the pathologic symptoms in the oral cavity, as "diabetic pyorrhea," "tuberculous pyorrhea," etc Only under such a classification can rational discussion be held on this subject. Take, for example "nephritic pyorrhea" and "diabetic pyorrhea" While renal abnormalities occur in the predisposing cause in each type, nevertheless, the symptomatology and treatment should be entirely different in each type When this point is conceded, due importance will thereafter be given to the necessity of making clear the nature of the predisposing cause of the cases under discussion

It is well understood in general surgery that operative procedure is attended with great danger to life itself in patients suffering from diabetes not under control Consequently, the same danger to life exists when surgical interference is commenced in pyorrhea when there is present an active condition of diabetes The at one time well nigh universal habit of dentists using surgical intervention in diabetics without making any diagnosis of the predisposing cause has produced its quota of fatal consequences In advanced stages of fatal diseases, it would be unnecessary brutality to subject the patient to the discomforts of surgery On the other hand, when the disease is curable, it is of great importance that the stomatologist should be given an accurate statement by the internist of every body disturbance, so that all local treatment should proceed in therapeutic harmony with the general treatment

Prognosis of pyorrhea or gingivitis must largely depend on the possibility of obtaining a cure of the malnutritional factor It is for this reason that the results of all physical examination, etc, should be in the hands of the stomatologist, so that he cannot only work in harmony with the physician, but also keep accurate record of any tissue changes that may take place

When the preponderating importance of an accurate diagnosis of the predisposing cause of pyorrhea is appreciated, an important factor in the maintenance of our point of view is established to the effect that the dentist treating these and all other mouth diseases should be as efficiently educated in general medicine as is the specialist in any other department of medicine

Heredity and Cancer—A committee of the life insurance companies in cooperation with the American Society for the Control of Cancer in a recent investigation on various phases of the cancer problem, found, among other things, from the records of a large life insurance company, that among 20 000 applicants for life insurance whose parents had both died of cancer, only four had cancer Out of 492 instances in which one or both parents had died of cancer, 43 per cent of the other parents had died of some other disease, 56 per cent were living at the average age of 61, and less than 1 per cent (four out of 492) had died from cancer—Arthur Hunter, President, Actuarial Society of America, *Insurance*, Dec 22, 1916

SOME STUDIES IN THE TREATMENT OF PYORRHEA ALVEOLARIS [*]

GEORGE BAILEY HARRIS, D.D.S., Sc.M.

DETROIT

In the consideration of the treatment of pyorrhea alveolaris, as with any other disease, we must presuppose a knowledge of the disease. There are, however, so many conditions suggested as being causative factors in pyorrhea, that it is hardly possible to assume that any one of them is responsible for pyorrhea, to the exclusion of the rest. Among the conditions which have been advanced as being causative agents in pyorrhea might be mentioned syphilis, rheumatism, liver affections and autointoxication. These conditions and any other which will lower the resistance of the tissues must be considered as causative factors in pyorrhea, and their eradication, wherever possible, must be accomplished when the treatment of pyorrhea is undertaken.

Pyorrhea should be looked on as an infectious disease and treated as such. Its inception, then, is based on the resistance of the tissues to bacterial invasion, which must be lowered before the infection can be overcome. This means the building up of the resistive forces throughout the entire body, as it is difficult to perceive how the resistance, under these conditions, can be raised in the gum tissues alone. This must be done not only to throw off the present infection but also to guard against its recurrence. The lowered resistance to the tissues surrounding the teeth is due, in many cases, to the well known calcium deposits and irritations produced by faulty dental work. These conditions must be corrected.

If, however, we better understood the causes of pyorrhea and knew more about the tissues most vitally involved in making a repair, we would be able to treat this disease more intelligently, and there would result a greatly increased number of recoveries.

I have been greatly surprised at the wonderful recuperative power of the cementum. The literature relating to this tissue is confined, in the main, to its description and histologic structure, very little being said about its use. Cementum is the bond between the teeth and the bone, the tooth and bone seemingly being unable to form a union themselves. It seems to have about the same recuperative power as bone, and, furthermore, under proper conditions, cementum has the power to regenerate, after it has been cut in grooves or removed entirely from the root, provided a sufficient amount of the cementum is left on the root from which regeneration can take place. THE ETIOLOGY AND TREATMENT OF INTERSTITIAL GINGIVITIS *

EUGENE S TALBOT, M D DDS
CHICAGO

My researches on interstitial gingivitis and pyorrhea alveolaris[1] were published in book form in 1899 In this work every conceivable phase of the disease was studied on animals as well as man The pathology was beautifully illustrated from its beginning to the formation of abscess, on the one hand, and exfoliation of the teeth, on the other

The object of this paper is to try to make clear the etiology, pathology and treatment based on the researches laid down in my work

The tissues about the roots of the tooth may become diseased under extreme local irritation or from constitutional disease, but as a rule the progress of tissue building about the first and second set of teeth prevents tissue degeneration Not until the bone has obtained its growth, from 27 to 35 years of age, does degeneration take place to any great extent, although marked inflammation of the gums may be present When the alveolar process has obtained its growth about the second teeth, the bone may be said to have reached the senile stage, and absorption under favorable conditions begins

THE ETIOLOGY

In considering the etiology of interstitial gingivitis, my researches have shown that the tissues surrounding the roots are end-organs, owing partially to the fact that the teeth, so far as nerves and blood vessels are concerned, are foreign bodies, and partly to the end-structure of the bone An end-organ is a structure in the body in which nerves and arteries extend to the extreme end and then stop The veins being extremely sluggish, the blood containing poison remains, and, being unable to return, sets up a low form of inflammation The dental pulp is the best example of an end-organ in the human body A study of this structure under the microscope, of persons over 40 years of age, will reveal all the degenerative pathologic conditions possible[2]

The blood, then, which flows into the alveolar process, owing to local irritation about the gum margin or root of the tooth, does not return into the circulation Blood charged with metallic, drug or body poisons collects in the alveolar process and produces irritation Stasis results (Fig 58, Interstitial Gingivitis[1]), nutrition is cut off, and a low form of inflammation is produced Nerve end degeneration takes place, endarteritis obliterans, and arteriosclerosis occurs

Ziegler[3] says

> The causes of inflammation may lie either in mechanical, thermal electrical or chemical influences, as well as in the influence of parasites The common characteristic of all these injurious agencies is the production, in the first place, of a local tissue degeneration, which, when of a certain extent and intensity is associated with disturbances of the circulation and of vascular secretion

This exactly describes the condition found in the alveolar process Stasis of blood in interstitial gingivitis is, then, due to mechanical irritation and possibly chemical changes in the blood

Ziegler[3] again says

> Under the designation inflammation are grouped those pathological processes, consisting on the one hand of tissue degenerations and tissue proliferations, and on the other, pathological exudations from the blood vessels

In this particular form of inflammation, tissue degeneration takes place There is no pain, heat or swelling as observed in the other forms of inflammation

When we consider the peculiar endotransitory nature of the alveolar process, degeneration of tissue is the natural result At the senile period when the excretory organs are diminishing in activity and in disease, vital resistance is at its lowest ebb, metabolism is diminished, and degeneration and absorption of the alveolar process is in active operation As age advances, the destruction of bone is a natural normal pathologic process

The disturbances in circulation bring about tissue degeneration because the gingival border of bone is very thin, transitory and easily destroyed The action of this mechanical irritation is to produce artery changes, nerve end degeneration and absorption of bone about the arteries, called halisteresis Stasis of blood may take place in a circumscribed area, or on the entire border of the alveolar process, or the apical end of one or more roots may be involved This depends on the nature and quality of the irritant The nature and severity of the irritation, stasis of blood and a lowered vitality of the patients will also determine the extent of the destruction of tissue, whether the irritation is located at the apical end of

the root, midway between the apex and the cervical margin, or at the cervical margin

When the inflammation has once become established at the cervical margin, the absorption is progressive to a greater or less extent until the tooth or teeth are removed Owing to the transitory nature of the alveolar process when irritation and stasis of blood occur, the nutrition of the part is interfered with and the bone tissue may be partially or wholly destroyed, leaving the fibrous tissue (trabeculae) undisturbed, thus holding the tooth firmly in position, although it can be moved laterally by the fingers In most cases, however, the entire structure, including the fibrous tissue, is destroyed

My researches have shown that the deposits on the roots of the tooth, other than tartar, are the detritus of destroyed bone and not deposits from the blood, as was formerly supposed The pus stage is an afterconsideration, and has nothing to do with the disease

In summing up the etiology, then, in this disease 1 We have to contend with the bone as an end-organ in which the blood accumulates (stasis) 2 Stasis of blood cuts off nutrition 3 Local and constitutional irritation and chemical changes in the blood set up a low form of inflammation and bone absorption 4 The absorption is enhanced because of the transitory nature of the alveolar process 5 Nerve end degeneration and arteriosclerosis occur 6 Want of vital resistance assists absorption

LOCAL TREATMENT

The first symptom of interstitial gingivitis is bleeding of the gums on the slightest injury The classification of the different phases of the disease renders the treatment, so far as we are capable of directing it, simple and easy

The first thing that naturally comes to the mind of the operator is to remove the cause The local treatment may begin immediately For personal reasons of cleanliness of the patient and the operator, one or two applications of iodin should first be made to the gums, which will destroy the germs and cleanse the mouth After this has been accomplished, the removal of all local irritation may begin

We have seen that stasis of blood cuts off *nutrition*, causing degeneration of tissue (absorption of bone). *The main object to be obtained in the treatment of this disease is to remove the stagnant blood, reestablish the metabolic process and cause a normal flow of fresh blood to nourish the parts* The nutrition of the part must be renewed that Nature may restore the tissues to health

How shall this be accomplished? To remove congested blood, physicians, from fifty to a hundred years ago, resorted to cupping, leeches and scarifying the tissues These methods must be resorted to at the present time in treating this disease If the gums are congested and festoons hang down between the crowns of the teeth, they may be removed on a line with the alveolar border with a lance

The gums should be allowed to bleed as freely as possible In removing the deposits from the roots of the teeth, the parts may be injured as much as possible with as little pain to the patient as possible, the germs having first been destroyed In this way much of the congested blood can be removed

The suction process, not unlike the old method of cupping, is excellent when properly performed

Scarifying the gums is also a good method of procedure Vigorous gum massage with a stiff gum massage brush should now be employed to stimulate the tissues to healthy action

Before the operation and after bleeding, iodin should frequently be employed to destroy all germs in the mouth All loose teeth should be removed

The following preparation has been used since 1878

Water	10 parts or grams
Zinc iodid	15 parts or grams
Iodin	25 parts or grams
Glycerin	10 parts or grams

The iodin destroys all germs in the mouth and cleanses the tissues The zinc iodid is used to contract the tissues, the glycerin to assist absorption This preparation is applied to the gums, teeth and mucous membrane by a long, slender applicator with cotton wound about the end It should be applied as often as every other day if possible It is not to be used by the patient

Friction and stimulating methods must be employed by the vigorous use of a "gum massage brush" The brush should be so shaped that it will reach the festoons between all the teeth

It should be made of the stiffest unbleached bristles that can be obtained The brush should be inserted into the mouth, the mouth and teeth closed In performing this operation the mind should be concentrated on the gums and not the teeth When the tissues have become revitalized, deposits from the alveolar process on the roots of the teeth will cease to form

One of the best gum washes for the patient to use in connection with "gum massage" is that of the zinc sulphocarbolate recommended by Dr W H Whitslar of Cleveland This drug may be used in different strengths and in many forms The following is a combination which I use

GUM WASH

Zinc sulphocarbolate	60 grains
Alcohol	1 ounce
Distilled water	2 ounces
True oil of wintergreen	8 drops

The patient should use this gum wash and massage the gums three times a day The patient should be under the care of the operator at least two or three times a week, so that he may direct the treatment The treatment of interstitial gingivitis at the apical end of the roots must be carried out according to symptoms

CONSTITUTIONAL TREATMENT

While the local treatment is being conducted, the patient's general health should be inquired into A twenty-four hour sample of urine should be obtained, and a thorough laboratory examination made If there are casts and high acidity, and indican is abundant, meat should be excluded, the patient placed on a vegetable diet, and the acidity reduced The bowels should be kept open and large quantities of water consumed There are many methods of cleaning the system and bowels The following may be used to good effect, a teaspoonful in half a glass of warm water every four hours

Calcined magnesia (heavy)	½ ounce
Sodium bicarbonate	1½ ounces

If the patient has sugar, albumin or other complications, it is best to refer the patient to a physician for general treatment

By this method of treatment the patient, in the estimation of the average dentist, is cured, not, however, we must not devote all energy to these infections to the exclusion of foci in other parts of the body which may be the chief foci, and relief cannot be had until they are located and removed. Further, there are many roentgenograms which show rarefied areas around the apexes of the roots that are rightly interpreted as being foci of infection, but it must also be remembered that there are lots of others which show the same rarefied areas which are not foci of infection, being localities in which there possibly once was a focus but which has been removed, and the tissue not yet completely filled in, which may never completely take place. This is amply proved by using an aspirator and removing a portion of the content of that supposed focus, only to find it to be nearly free from bacteria. Except in extreme cases, therefore, there is no justification for the extraction of a tooth, simply because a roentgenogram showed a rarefied area, unless substantiated by other diagnosis. The extraction of teeth, in an effort to check infections in other parts of the body, just because a roentgenogram showed a rarefied area, except in extreme cases, is to be condemned. If this practice is to be indulged in, it must have its completion in the extraction of all devitalized teeth whether or not the Roentgen ray shows a rarefied area to be present. Also all teeth that are pyorrheic would have to be extracted because they are foci of infection, and those that are not yet affected would have to be extracted because they might become foci of infection.

THE ETIOLOGY AND TREATMENT OF INTERSTITIAL GINGIVITIS *

EUGENE S. TALBOT, M.D., D.D.S.
CHICAGO

My researches on interstitial gingivitis and pyorrhea alveolaris[1] were published in book form in 1899. In this work every conceivable phase of the disease was studied on animals as well as man. The pathology was beautifully illustrated from its beginning to the formation of abscess, on the one hand, and exfoliation of the teeth, on the other.

The object of this paper is to try to make clear the etiology, pathology and treatment based on the researches laid down in my work.

The tissues about the roots of the tooth may become diseased under extreme local irritation or from constitutional disease, but as a rule the progress of tissue building about the first and second set of teeth prevents tissue degeneration. Not until the bone has obtained its growth, from 27 to 35 years of age, does degeneration take place to any great extent, although marked inflammation of the gums may be present. When the alveolar process has obtained its growth about the second teeth, the bone may be said to have reached the senile stage, and absorption under favorable conditions begins.

THE ETIOLOGY

In considering the etiology of interstitial gingivitis, my researches have shown that the tissues surrounding the roots are end-organs, owing partially to the fact that the teeth, so far as nerves and blood vessels are concerned, are foreign bodies, and partly to the end-structure of the bone. An end-organ is a structure in the body in which nerves and arteries extend to the extreme end and then stop. The veins being extremely sluggish, the blood containing poison remains, and, being unable to return, sets up a low form of inflammation. The dental pulp is the best example of an end-organ in the human body. A study of this structure under the microscope, of persons over 40 years of age, will reveal all the degenerative pathologic conditions possible.[2]

The blood, then, which flows into the alveolar process, owing to local irritation about the gum margin or root of the tooth, does not return into the circulation. Blood charged with metallic, drug or body poisons collects in the alveolar process and produces irritation. Stasis results (Fig. 58, Interstitial Gingivitis[1]), nutrition is cut off, and a low form of inflammation is produced. Nerve end degeneration takes place, endarteritis obliterans, and arteriosclerosis occurs.

Ziegler[3] says:

> The causes of inflammation may lie either in mechanical, thermal, electrical or chemical influences, as well as in the influence of parasites. The common characteristic of all these injurious agencies is the production, in the first place, of a local tissue degeneration, which, when of a certain extent and intensity, is associated with disturbances of the circulation and of vascular secretion.

This exactly describes the condition found in the alveolar process. Stasis of blood in interstitial gingivitis is, then, due to mechanical irritation and possibly chemical changes in the blood.

Ziegler[3] again says:

> Under the designation inflammation are grouped those pathological processes, consisting on the one hand of tissue degenerations and tissue proliferations, and on the other, pathological exudations from the blood vessels.

In this particular form of inflammation, tissue degeneration takes place. There is no pain, heat or swelling as observed in the other forms of inflammation.

When we consider the peculiar endotransitory nature of the alveolar process, degeneration of tissue is the natural result. At the senile period when the excretory organs are diminishing in activity and in disease, vital resistance is at its lowest ebb, metabolism is diminished, and degeneration and absorption of the alveolar process is in active operation. As age advances, the destruction of bone is a natural normal pathologic process.

The disturbances in circulation bring about tissue degeneration because the gingival border of bone is very thin, transitory and easily destroyed. The action of this mechanical irritation is to produce artery changes, nerve end degeneration and absorption of bone about the arteries, called halisteresis. Stasis of blood may take place in a circumscribed area, or on the entire border of the alveolar process, or the apical end of one or more roots may be involved. This depends on the nature and quality of the irritant. The nature and severity of the irritation, stasis of blood and a lowered vitality of the patients will also determine the extent of the destruction of tissue, whether the irritation is located at the apical end of

the root, midway between the apex and the cervical margin, or at the cervical margin

When the inflammation has once become established at the cervical margin, the absorption is progressive to a greater or less extent until the tooth or teeth are removed Owing to the transitory nature of the alveolar process when irritation and stasis of blood occur, the nutrition of the part is interfered with and the bone tissue may be partially or wholly destroyed, leaving the fibrous tissue (trabeculae) undisturbed, thus holding the tooth firmly in position, although it can be moved laterally by the fingers In most cases, however, the entire structure, including the fibrous tissue, is destroyed

My researches have shown that the deposits on the roots of the tooth, other than tartar, are the detritus of destroyed bone and not deposits from the blood, as was formerly supposed The pus stage is an afterconsideration, and has nothing to do with the disease

In summing up the etiology, then, in this disease 1 We have to contend with the bone as an end-organ in which the blood accumulates (stasis) 2 Stasis of blood cuts off nutrition 3 Local and constitutional irritation and chemical changes in the blood set up a low form of inflammation and bone absorption 4 The absorption is enhanced because of the transitory nature of the alveolar process 5 Nerve end degeneration and arteriosclerosis occur 6 Want of vital resistance assists absorption

LOCAL TREATMENT

The first symptom of interstitial gingivitis is bleeding of the gums on the slightest injury The classification of the different phases of the disease renders the treatment, so far as we are capable of directing it, simple and easy

The first thing that naturally comes to the mind of the operator is to remove the cause The local treatment may begin immediately For personal reasons of cleanliness of the patient and the operator, one or two applications of iodin should first be made to the gums, which will destroy the germs and cleanse the mouth After this has been accomplished, the removal of all local irritation may begin

We have seen that stasis of blood cuts off nutrition, causing degeneration of tissue (absorption of bone) *The main object to be obtained in the treatment of this disease is to remove the stagnant blood, reestablish the metabolic process and cause a normal flow of fresh blood to nourish the parts* The nutrition of the part must be renewed that Nature may restore the tissues to health

How shall this be accomplished? To remove congested blood, physicians, from fifty to a hundred years ago, resorted to cupping, leeches and scarifying the tissues These methods must be resorted to at the present time in treating this disease If the gums are congested and festoons hang down between the crowns of the teeth, they may be removed on a line with the alveolar border with a lance

The gums should be allowed to bleed as freely as possible In removing the deposits from the roots of the teeth, the parts may be injured as much as possible with as little pain to the patient as possible, the germs having first been destroyed In this way much of the congested blood can be removed

The suction process, not unlike the old method of cupping, is excellent when properly performed Scarifying the gums is also a good method of procedure Vigorous gum massage with a stiff gum massage brush should now be employed to stimulate the tissues to healthy action

Before the operation and after bleeding, iodin should frequently be employed to destroy all germs in the mouth All loose teeth should be removed

The following preparation has been used since 1878

Water	10 parts or grams
Zinc iodid	15 parts or grams
Iodin	25 parts or grams
Glycerin	10 parts or grams

The iodin destroys all germs in the mouth and cleanses the tissues The zinc iodid is used to contract the tissues, the glycerin to assist absorption This preparation is applied to the gums, teeth and mucous membrane by a long, slender applicator with cotton wound about the end It should be applied as often as every other day if possible It is not to be used by the patient

Friction and stimulating methods must be employed by the vigorous use of a "gum massage brush" The brush should be so shaped that it will reach the festoons between all the teeth

It should be made of the stiffest unbleached bristles that can be obtained The brush should be inserted into the mouth, the mouth and teeth closed In performing this operation the mind should be concentrated on the gums and not the teeth When the tissues have become revitalized, deposits from the alveolar process on the roots of the teeth will cease to form

One of the best gum washes for the patient to use in connection with "gum massage" is that of the zinc sulphocarbolate recommended by Dr W H Whitslar of Cleveland This drug may be used in different strengths and in many forms The following is a combination which I use

GUM WASH

Zinc sulphocarbolate	60 grains
Alcohol	1 ounce
Distilled water	2 ounces
True oil of wintergreen	8 drops

The patient should use this gum wash and massage the gums three times a day The patient should be under the care of the operator at least two or three times a week, so that he may direct the treatment The treatment of interstitial gingivitis at the apical end of the roots must be carried out according to symptoms

CONSTITUTIONAL TREATMENT

While the local treatment is being conducted, the patient's general health should be inquired into A twenty-four hour sample of urine should be obtained, and a thorough laboratory examination made If there are casts and high acidity, and indican is abundant, meat should be excluded, the patient placed on a vegetable diet, and the acidity reduced The bowels should be kept open and large quantities of water consumed There are many methods of cleaning the system and bowels The following may be used to good effect, a teaspoonful in half a glass of warm water every four hours

Calcined magnesia (heavy)	½ ounce
Sodium bicarbonate	1½ ounces

If the patient has sugar, albumin or other complications, it is best to refer the patient to a physician for general treatment

By this method of treatment the patient, in the estimation of the average dentist, is cured, not, however, as other diseases of the body are cured Eternal vigilance is necessary on the part of both operator and patient to prevent blood from again collecting in the blood vessels of the alveolar process, and a return of the disease

The bone is still an endotransitory structure, and having once become diseased, it is much easier for the stasis of blood again to take place As the patient advances in years, the excretory organs become senile, poisons collect in the blood, resistance is lowered, and there is a gradual absorption of bone taking place about the teeth throughout life

31 North State Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS LESCOHIER, POTTER, RHEIN, HARRIS AND TALBOT

Dr Arthur D Black, Chicago The first most outstanding feature of the pathology of this group of diseases is their chronicity and this has possibly contributed much to the difficulty of a clear understanding of the pathology This condition, which I will term a chronic suppurative pericementitis, will, in the average case, be progressive extending over ten fifteen or even thirty years In those cases where we have a systemic cause as the principal one, we would naturally expect to find a general involvement of the peridental tissues Except for some added local exciting cause, there is no reason why one or a few teeth should be picked out, all of the teeth should be included in the manifestation of the disease where the systemic condition is the principal cause On the other hand, in those cases where a limited number of teeth are involved, we would naturally expect to find that the local exciting causes had played the primary role As to the bacteriology many men have endeavored to find a specific organism which could be associated with this disease, and they have failed One fact argues against a specific organism as being the cause, and that is the progress in these pockets, and this progress is very much more rapid toward the apexes than laterally around the roots We observe many cases in which from an original pocket there have developed a number of other surface pockets, without any involvement of contiguous surfaces of the teeth The tendency is for a tooth to move away from the side of the pocket, because encircling each tooth are the fibers of the peridental membrane These are on a tension and when the tissue is destroyed on one side of the root the balance of those fibers is lost, and the fibers of the opposite side draw the tooth in that direction, unless some obstruction of occlusion prevents this There never is a detachment of the peridental membrane alongside the root that is not preceded by a gingivitis In the destruction of the tissues about the root one of the earliest manifestations of the presence of a pocket alongside the root is a stripping off of these tissues from the cementum As time passes there is left a connective tissue which has nothing which may differentiate it from a general connective tissue Those elements which are necessary to a normal reattachment of tissue to the tooth are lost What else has happened? The cementum has absorbed the products of that suppurative process It has been changed from a positively chemotactic tissue into a negatively chemotactic tissue, which will repel tissue attachment

As to rebuilding of the cementum I have examined many cases and seen many in which there has been an absorption, not only of the cementum, but of a considerable portion of the dentin of the tooth, but I have never seen any in which there was a detachment in that area They were not infected cases, there had been no suppuration They were not cases in which, if you leave the end of a root, you will find cementum building over it Dentin has no power of rebuilding cementum Some one said it was closely comparable to bone It is, except that it has no circulation Its life depends on the cementoblasts on its surface No changes take place within it As the pocket progresses farther down the side of the root, we must expect the first absorption of the alveolar process to take place near the crest, and then as it continues around the root, in cases of long standing we have a funnel formation in the bone That is one of the marked symptoms of progress of this disease I would like to criticize Dr Potter's use of the term erosion in connection with these destructions or absorptions of the bone It seems to me that the term rarefication is hardly applicable to these cases, because the bone is either destroyed or absorbed Dr Potter spoke of looseness and tightness of some of these teeth Many times we have a very loose tooth, so far as motion is concerned, and yet it is difficult to extract As a result of inflammation, the fibers of the peridental membrane which remain attached to that tooth have lost their tonicity, they are not taut, and are apparently lengthened considerably, so that the tooth has an excessive motion, which does not at all compare with the amount of destruction of tissue which has occurred Treatment will tone up those fibers and they will again exert their normal pull

Dr Floyd D Leach, Chicago There is a certain amount of tooth movement laterally, that is, from buccal to lingual Dr Black said something about a peculiar action of the micro organisms which caused a destruction of the investing tissues of the teeth, especially along the proximal surfaces of the roots We have all seen this condition, causing the breaking down of the contents, due to the lateral motion in the act of mastication It is not easy to guess or feel quite sure that those fibers of the peridental membrane which die to the buccal, labial and lingual sides of the socket should take the mechanical strain I have an idea this condition may be the reason why the progress of the destruction is more pronounced on the proximal surfaces of the roots than on the buccal labial and lingual You have always noticed that the pockets are really on the interproximal surfaces The gum would recede from the lingual labial and buccal surfaces of the roots, and still in a great many cases be very firm as to attachment Food substances constantly massaging these areas, and the friction of the brush when a brush is used in cleansing the gums and teeth stimulate to a greater extent those areas on the buccal, labial and lingual surfaces But I think the mechanical arrangement of the fibers adds more resistance more tone and more strength to these buccal, labial and lingual vestiges

Dr Russell W Bunting Ann Arbor, Mich We have been told by some that pyorrhea is the result largely of constitutional factors, and by others that pyorrhea is the result of local disturbance, such as infection and irritation Almost all have agreed that very frequently there are combinations of these two May I present this view of the situation? May we say that pyorrhea is caused by an exciting condition, such as the infection which destroys the tissues about the teeth and severs their attachment? But infection is not the determining cause? The determining factors are all the predisposing causes, either local or general, which make the characteristic action of the exciting causes possible I like Dr Rhein's statement that healthy tissues cannot be infected How often have we seen ten times the local infection that would be necessary to produce pyorrhea existing in the mouth, and no pyorrhea present? Why? Because those tissues were so healthy that they were not infected, even under very untoward local conditions If this is true, we must recognize not only the local but the general conditions as causative factors As Dr Rhein said, our constitutional factors are often so obscure that the ablest and most careful internist cannot detect where they are located, or what their nature is The infective condition alone which is present in the mouth could not have produced the pyorrhea in such cases but for that remote constitutional condition which made it possible for this to happen Fortunately, we find that very frequently the clearing up of the local causes allows the tissues to come back to an apparent normality

Can we cure pyorrhea? I have taken the stand that we cannot cure pyorrhea unless we can obliterate the pockets Dr Harris said that the pocket may be obliterated because cementum is built on the denuded surface, and that new attachment is had to the tooth Dr Black does not believe that pyorrheic teeth can ever have a reattachment We must admit that if pyorrhea is to be cured absolutely, either the soft tissues must be reattached to the tooth completely up to the free line of the gum or else the gum line must be retracted down to the place on the root at which it is attached If it is true that these tissues can never be reattached, why should we not treat pyorrhea by opening the pockets, cutting away all overlying tissue, clear down to the bottom of the pockets, exposing the healthy tissue and allow it to heal? We would then have obliterated the pocket and the pyorrhea But is that the only way in which it may be done? It is my conviction that the tissues may be made to physically join to the surface of the root after they have been denuded from it in the formation of a pyorrhea pocket, if the conditions are right I have had many specific instances of pockets, in which I could get one quarter, one half or three quarters of the length of the root with an explorer, or any other instrument, and at the conclusion of a month or two of surgical treatment, assisting the tissues to return to as near the normal as possible I have been unable to get the finest instrument between those soft tissues and the root of the tooth in the identical place where the pockets had existed previously What has taken place in those pockets? Are there any other two tissues in the body that would so approximate and still not be physically attached? I do not think so Let us take a surface view of that pocket Pyorrhea seldom goes down circumferentially, attacking the tissues equally It rather goes down one surface If we prepare this root surgically and make it clean we have remaining on either side living, healthy pericementum, which is capable of reproduction and filling in the space with new tissue This is laid down first in the form of granulation tissue from which tissues may develop having the propensity to form a bony-like material, or even true bone, which may be deposited on the surface of the root, and attach those primitive fibers, or embryonic type of transitional tissue, to the surface of that root When a root is resorbed there is in many cases entire breaking up of the fibers The bone is entirely taken out at a given area and only a transitory type of tissue remains Dr Black said that in one case the destruction was not infective and that in the other it was But was it not destroyed in both cases and what is the difference? There are cases on record in the literature in which a bone has been cut across, a section has been taken out, and in the gap there has been placed an ivory bit that reproduced as nearly as possible the bone which was removed Later that section has been removed and has been examined in microscopic section It was found that the ivory had about it a layer of new bone which was quite like a lamellar bone placed on the outside of the ivory Outside of the bony layer a soft tissue formed, quite like periosteum These tissues had adapted themselves to form a direct attachment of soft tissue by a bone forming process to the ivory, in which there was no circulation without which Dr Black stated reattachment could not occur We are told that exactly the same thing has been done with platinum in which bone has been laid on top of platinum and the soft tissues glued to the platinum in the same manner

Dr Eugene S Talbot, Chicago I conceive an entirely different condition of things than has been explained to you by Dr Black and Dr Bunting in regard to pockets There is no question about the pathology It is all laid down in my work and has been verified in a great many different methods of experimentation My own researches explain that many of the statements, made by Dr Black and Dr Bunting, are much more simple than the points brought out by them For instance arteries run through the alveolar process and the peridental membrane When irritation takes place, whether local or constitutional, the artery is filled with irritation If constitutional, it may be poison, if local, it may be anything that produces a local irritation If you will examine the illustrations in my book, you will find that the bone extends around the artery The irritation, then, is set up in and around the artery, and if there are a dozen arteries there are a dozen points of irritation, inflammation and absorption, and the absorption starts out from the artery We will say that this irritation is due to lead or mercurial poison That material is carried down into the artery, and it may extend clear to the end of the root What has taken place? Absorption has taken place around that artery and only one artery is involved Absorption has gone down to the end of the root But if the irritation is greater, either constitutional or local, these arteries passing in a lateral direction, as well as those passing longitudinally, may absorb the entire process on the one side of the tooth, while absorption has taken place downward in the other case clear to the end of the root in one or two arteries To explain Dr Bunting's point about filling up of the alveolar process with new material if the inflammation has extended down the side of the root, with one two or three arteries involved, the bone is liable to heal up if the cause is removed If, on the other hand, the bone has been entirely destroyed downward and pockets have been formed, that bone is never restored, because the fibrous tissue is entirely lost Bone absorption takes place by halisteresis before the fibers of the peridental membrane are destroyed—just the reverse of Dr Black's idea

Dr Meyer L Rhein, New York Not a thing has been said in regard to cemental repair that can be denied under certain conditions, and yet we have listened to statements that appear to be absolutely in opposition to each other I know that Dr Bunting is correct in what he has said I know that exposed cementum can be repaired and the normal condition replaced, but each of the speakers has omitted to state in what conditions repair or lack of repair, takes place Dr Talbot gave a very lucid description of what takes place in the tissue when arteriosclerotic conditions manifest themselves We get these conditions in certain forms approaching the period of senility, in certain forms of malnutrition, nephritic and diabetic conditions, and under such conditions that repair of the kind that Dr Bunting spoke of is impossible Why does a pocket form? We get a pocket on account of imperfect nutrition to that particular spot and as a consequence there is the impossibility of repair which must ordinarily take place throughout the body daily The same conditions that produce pyorrheal conditions are at work in erosion, where there is found a continuing loss of gum tissue, exposing the root surface except that the local resistance, due to many causes has prevented infection from taking place In other words, in the retraction of the gum which results in the exposure of considerable of the root surface of the teeth, we meet with the same lack of nutrition that is demanded at every ultimate point of nutritional circulation Pyorrhea may occur in people suffering from fatty degeneration about the heart What are the appearances of the mouth in this condition? There is no suppuration There is no deposit on the roots, but very extensive pockets that frequently go down deep, and we find the gum in ribbons over these pockets They are great big flabby pockets, with a deterioration in color and character of the circulation I have never seen one with any purulent condition I have seen those gums come back absolutely to what we would consider comparatively healthy gum tissue under the Nauheim treatment If the malnutritional factor has disappeared after treatment, you may call that patient cured What is the reason that exposed cementum considering that there is no condition of malnutrition present will not permit the tissues to recover? It is due to the fact of exposure of this cemental surface to the irritating fluids that are in circulation I believe it will take exceptional conditions to permit a cemental surface that has suffered abrasion to repair because of the danger of retrograde metamorphosis going on from its exposure to the fluids of the mouth, consequently the therapy must be of such a mechanical nature to cover that cementum that it will not be exposed to the fluids of the mouth I have done this for many years by coating the surface of such cementum with chloropercha, keeping the exposed cementum hermetically sealed and thus protecting it from the fluids of the mouth

Dr George B Harris, Detroit I have been misunderstood a little in regard to the regeneration of cementum In the first place, I do not wish to be understood as saying a complete regeneration takes place The point I wanted to bring out is that there are cases in which the cementum has regenerated, and these cases were not under aseptic conditions Can anybody imagine the crown of a tooth cut off below the gingival margins or split half the length of the root with the cementum forming over it, and say that this portion was in an aseptic condition? I do not believe it Further, where the cementum is diseased we can remove it, leaving nothing but the healthy cementum below, producing a condition that is as near aseptic as it is possible to get under the conditions, a condition at least equal to those mentioned where the cementum did reform It is possible, then, that the cementum will reform there Whether it ever has or not, I do not know, because there is no way of measuring it as it takes place in the mouth, unless you would happen to find a tooth where the difference in density of the cementum will show, or where it would be shown by the new cementum making a thicker coating

Dr G H Smith, Medina, O This subject of pyorrhea has been of intense interest to me for five years, and I would like to suggest to the medical profession that they advise more of their patients to select an ethical dentist Dr Moorehead made a statement in his address that I can hardly substantiate He claims that only 10 per cent of the dentists were efficient There are dentists commercializing, but with the cooperation and advice of the medical profession many patients would escape many dental disorders

Dr William C Fisher, New York I want to ask Dr Rhein if I understood him to say that in a diabetic patient he would not consider operative procedure as being wise, or that it had been known to even be fatal?

Dr Rhein Correct I said diabetes not under control

Dr Fisher I am not thoroughly convinced that a dental operation is precluded in any patient—diabetic or otherwise—who is able to visit your office and go about his business I believe of course, in the medical treatment, but I certainly think that there is absolutely no shock such as that experienced in a major operation while treating these patients In pyorrhea I use the several solutions of iodin Dr Talbot spoke of gum massage with the brush Do you mean the hand or engine brush?

Dr Talbot The hand brush

Dr Fisher I was afraid that possibly you meant the engine brush In polishing teeth we want to get away from anything that will in any manner injure or tear the tissues, and I have devised a simple little mandril of one piece of steel I use French tubing of different sizes to fit and make my polishing powder, mixing in with that iodin As this mandril revolves in the engine, the French tubing will flare out on the surface and coax up the gum whether receded or not, and polish the surface beneath the gingiva In the interproximal spaces select a smaller piece of tubing and it is possible to get a polished surface there With that method you get a massaging of the gum which the patient cannot possibly give it You are massaging the gum at the same time that you are polishing the neck of the tooth where it has been scaled

Dr W A Price, Cleveland Two decades find us almost exactly where we were when I started to practice dentistry twenty-three years ago We cannot come together and express a common idea relative to the etiology of pyorrhea and be united in supporting and substantiating it We have made practically no study whatever of protein absorption, which takes place around these pyorrheal infections A large number of nervous lesions of the body have apparently been traced directly to dental infections and to pyorrhea. The medical profession must bring these patients back to us for treatment, and we cannot even give the A, B, C of the infection in pyorrhea We do not know the nature or the morphology of 50 per cent of the bacteria that grow in pyorrhea pockets They have not been grown artificially What is the solution? If I were to ask Dr Talbot how he got his information that has been the great cornerstone for a large part of this work he would say 'Hours and hours, and days and days, and years and years of hard work" How many men are devoting a worthy effort to this work? We are called on to redouble our efforts to answer with some degree of intelligence this great question of the etiology of pyorrhea, which today we know almost nothing about

Dr Hollis E Potter Chicago I can see now that the pockets we are showing with the Roentgen rays represent more absorption of bone than any such slight detachment as you have been talking about I should think that in cases where we are showing Roentgen ray findings of absorption around a tooth, when we are talking about a pocket it is a very gross condition as compared with the small and limited pockets that the controversy is about this afternoon

Dr Alexander W Lescohier, Detroit As Dr Price said, it is possible that there are many good things we do not know about the bacteriology of pyorrhea, but there is one fact which I do believe has been established, namely, the preponderance of streptococcic infection I do not mean to imply that the streptococcus is the cause of pyorrhea bacterial infection being apparently a secondary element, characteristic of the pustular stage and not of the initial condition But, in view of its potential virulence and the persistency with which the streptococcus is found, it is indicated that certain strains have a peculiar affinity for the peridental tissues Also that as far as the sequelae of pyorrheal infection are concerned, particularly the arthritic, the streptococcus overshadows in importance other micro organisms

Dr H A Potts, Chicago May I ask if it has been determined whether or not this streptococcus which he finds in pyorrhea is an aerobic or an anaerobic one, whether hemolytic or the *Streptococcus viridans,* and what connection there is between the effects of these streptococci of pyorrheal infection and those found in chronic abscess?

Dr Lescohier I cannot answer definitely the questions raised The work of Hartzell and others has indicated that the *Streptococcus viridans* is found much more frequently than any other type, but hemolytic streptococci are also observed in some cases I would not undertake to answer the question as to the relationship between streptococci elsewhere and those in pyorrhea and alveolar abscess

Dr Meyer L Rhein, New York I do not want to let the inference go that I am oblivious to the fact that it is necessary to have an attacking organism when we come to this stage of infection There seems to be a strong elective affinity of certain micro-organisms to attack the gingival tissue dependent on certain malnutritional predisposing causes There is a type of pyorrhea due to certain kinds of malnutritional causes where the attacking organism is a protozoon I have cured three distinct cases of pyorrhea in the last two years with emetin and I failed in numerous other cases Now why should this be? It simply carries out in the ultimate analysis what Dr Lescohier's paper has shown us, that there is no one specific organism in pyorrhea The three patients I cured all seemed to have the same kind of malnutritional predisposing causes they were all cases of intense inflammation and infective conditions in the larger colon They were cases that had shown symptoms that very closely resembled epidemic forms of dysentery Now, is it illogical, is it surprising, that in a condition of that kind, where we know the endameba plays the role of attacking force, that when by reason of this predisposing cause the mouth shows the evidence of pyorrhea we should find the same organism again the attacking force? The place to find pyorrhea is not among the patients who come to the office of the dentist You will find pyorrhea almost everywhere About 85 per cent of the cases that the average dentist treats as pyorrhea are nothing more than some focal infection that has been diagnosed improperly and in which a roentgenogram would demonstrate the error of the diagnosis In chronic alveolar abscess, with its sinus opening out into the mouth sooner or later symptoms appear that approach and grossly deceive the careless diagnostician, and there is no reason why you cannot get an alveolar abscess with a pyorrhea complication, if you want to call it such, that is dependent entirely on the apical infection I have found such a condition in a considerable number of cases On careful differential diagnosis I could put my hands on the point of focal infection That is especially true in cases where there seem to be one or two teeth only subject to pyorrhea When an individual comes with a pyorrhea in one or two teeth, the diagnosis is open to grave suspicion I have found the focal infection of a pyorrhea showing in an upper incisor, away back in the roots of a second molar, and I recall quite well the difficulty of making a diagnosis in that particular case I was a little surprised at Dr Fisher's question as though I was in doubt as to whether operative interference was to be avoided in diabetics where the diabetes was not under control It is not a question of a major operation that makes a surgical condition a most dangerous proposition under such conditions I know of no surgeon who would not seriously hesitate to do the most minor surgical operation on a patient showing a large percentage of sugar It is true that under certain conditions, when it becomes a question of life or death the surgeon will take chances He knows the patient is going to die from septic causes, and he is going to give that patient the benefit of that chance The deaths from teeth extraction in diabetics would fill a very large chapter if they could be brought together

DR. FISHER Does that mean from the anesthetic?

DR RHEIN No I am simply stating what is an abstract fact that is settled in the minds of surgeons, pathologists and bacteriologists at the present time In regard to research work We have had to have recourse to animal experimentation to a large extent, and I am convinced that all the dental research work on animals in the past is replete with error, because the mouth flora of the dog is so different from the mouth flora of the human that it cannot consistently be taken as the same in any experimental work on animals This is a very important factor, and it is far better for dental research work to proceed slowly and get results that are not going to be questioned in the future than to make comparisons and arrive at conclusions that cannot be verified

DR EUGENE S TALBOT, Chicago If you will examine the dental journals, and some of the medical journals, you will find that a large percentage of the pictures that have been shown are represented as abscesses Dr Potter has shown us that there are a great many different shades or conditions of the alveolar process which are not abscesses, and the reason for that is that we have a condition of absorption called halisteresis, and not lacunar absorption in the alveolar process, which may be or is due to the irritation that has taken place from the pulp chamber The degree of absorption will depend on the amount of irritation In regard to focal infection the dental profession can hardly be blamed for abscesses at the roots of the teeth after the canals have been treated and filled Up to within the last two or three years, when an abscess formed on the root of a tooth and the face swelled or a fistula had formed, the only means of knowing that the abscess was supposed to be cured was that the face became reduced to a normal state and remained so, the fistula healed and did not return These were the only symptoms available when the tooth remained quiet without pain or swelling which led the operator to believe that the abscess was cured With the modern methods of diagnosis, the Roentgen ray, we have learned that these signs are not for a moment to be considered The Roentgen ray demonstrates that very few abscesses are destroyed and healed, but that they remain cold or blind abscesses, discharging pus into the tissues for an indefinite length of time I recall one instance in which an abscess remained on the root of a left superior first molar for fifty-two years

---

Characteristics of the Chinese—It seems that the Chinese typically has a higher threshold of stimulation than the occidental It takes a larger summation of stimuli or a greater single stimulus in the first place to rise into consciousness, and in the second place to cause reflex activity So we see him impervious to noises, odors and sights which western nerves bear but poorly We see him existing with no complaint and no idea of betterment, in squalor, misery and poverty which western personality would find at once unendurable. We see him exercise a fatalistic indifference to the immediate or remote future, because no clear picture has arisen in his consciousness of any condition or time different from his own immediate present When the summation or single stimulus is sufficiently great, however, for sensation to appear in consciousness there is but a norrow margin of normal response before the reaction becomes pathological Hence it is that all the psychoses and neuroses are so easily aroused, since the zone of normal response is narrowed by the high threshold of stimulation Thus we see the superficial anomaly of sluggishness, inertia and indifference associated with a high and poorly controlled emotional nature which involves and easily goes over into hysteria and various emotional crises—Dr Alfred C Reed, *Scientific Monthly*, January, 1917

AN ANALYSIS OF FIFTY CASES OF SCIATICA *

MARK H ROGERS, MD
BOSTON

The purpose of analyzing a series of cases of sciatica and presenting it before this section is to discuss whether there is such a condition or clinical entity that is called essential or idiopathic sciatica Also I wish to discuss in relation to teaching, what should be taught, and in what department of the medical school should it be made the subject of teaching There is no question but that it is firmly fixed in the layman's mind that sciatica is a disease in itself, a distinct entity, and I am sure that the profession at large also is satisfied that it is an entity, although realizing that at times it may be a symptom of a lesion elsewhere If we appreciate that there is a definite cause in every case and that cause can be demonstrated as a physical fact, then much of the uncertainty will be changed and the treatment will become more rational and exact

What is the necessity for discussing this subject? That it is an indefinite and undecided condition is very well shown by any textbook on internal medicine or nervous diseases Either what the orthopedist believes to be true, and I suppose my experience as brought out in these fifty cases will correspond with yours, is entirely wrong, or else the various authorities on which we have to depend are giving a wrong conception of this condition

Let me quote from one of the authorities as to treatment

> Certain remedies are of service in sciatica Prolonged baths give excellent results The patient must remain in his bath for several hours Antipyrin may be prescribed in doses of from 15 to 45 grains Injections of morphin and inunction of an ointment of methyl salicylate may give relief Blister, the actual cautery, injections of sterilized water, injections of air, and epidural injections by the sacrococcygeal route have their indications Bleeding leeches and cuppings are useful

I am familiar with the teaching of two medical schools and as far as I know sciatica is not definitely taught as a part of the curriculum in either one I received no instruction as a student and supposed that it was a pure nerve lesion I rather believe that it is not considered of very great importance, and therefore falls between the departments of medicine, neurology and orthopedics Therefore we had to gather our knowledge from the textbooks and current literature, and enough has been said to show the confusion that exists, and this is the reason for presenting these facts

It may be argued that this is a rather selected group of cases, because I would be more likely to see cases with joint symptoms There is a certain element of truth to such a statement, but many of these cases had been definitely treated for sciatica by other men, with the idea that there was an inflammatory lesion of the nerve trunk I am sure that this series of cases represents what is commonly called sciatica Fifteen years ago there were reported from the nerve department of the Massachusetts General Hospital of Boston a large number of cases of sciatica, as shown in the annual report The other day I went over the records of this same department for the last six months and found three cases that were diagnosed sciatica One of the staff of that department analyzed these three records, and he could find no evidence of an essential sciatica In other words, they have no record of such a condition in the last six months

---

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

I was interested in discussing this question of essential sciatica with one of the older orthopedic men, and he said that most sciaticas were certainly due to joint lesion, but he supposed there must be real sciaticas But the point is that he never has seen one Several medical men of good standing have informed me that they have never recognized a case of so-called idiopathic sciatica Now, where certain groups of men recognize sciatica as a distinct disease, a perineuritis of the sciatic nerve, and that is the commonly accepted pathology, and another group are not sure that there is such a condition, it means either that our older teaching and the larger part of what the textbooks teach are wrong or that I have not seen the type of cases that they describe I believe such a fact as here presented in regard to the records of the nerve department of the Massachusetts General Hospital show that we are all dealing with the same type of case, but from a different point of view

As the analysis of this series will show that the lesion is located at the origin of the sciatic nerve, and not along the course of the nerve as is commonly taught, and as it is the contention that the most common cause is a joint lesion with a secondary effect on the nerve which is anatomically in close apposition to the joints which make up the lower part of the spine, it will be necessary first to consider the various points in the physical examination of any case of sciatica which indicate a joint lesion

To study the physical examination of such a well-known condition as sciatica would seem to be unnecessary, but certain features seem to me to be overemphasized and are always explained on the basis of a nerve lesion It is quite easy to demonstrate that an acute attack of sciatica has a definite joint basis, but it is more difficult to explain the cases that show a milder degree of pain and that are more chronic in character, because the symptoms referable to a joint are less marked than the resulting nerve pain

The evidences of a lesion of any joint, whether due to disease or to trauma, is definite and clear cut They are pain referred to a joint, tenderness to touch, limitation of motion, deformity resulting from muscular spasm or from a permanent lesion, and changes in the joint as shown by the Roentgen-ray

It is very common in sciatica to have the pain referred to the lower portion of the spine, starting from that region and extending down the course of the nerve Often the patient will put one finger directly over the sacro-iliac joint or the lumbosacral joint and locate the pain definitely at the joint

In the acute cases, those that are due to an acute joint trouble, there may be definite tenderness to touch over one of the articulations, and sometimes this may cause pain down the sciatic nerve Of course, it is impossible to cause direct pressure on the nerve by pressing on the posterior surface of the joint, so the effect must be through a sensitive joint and thus to the nerve which lies anterior to the joint

Limitation of motion of a joint does not need any explanation as an indication of a joint lesion, except to explain how it is detected in lesions about the lower portion of the spine It may be observed while the patient is standing, and then it will be noticed that forward, lateral or backward bending will either be definitely restricted or will cause pain A more delicate test is to have the patient, while lying on the back and with the knee held straight, flex the leg on the abdomen This is the Kernig test and has always been explained as causing pain because it stretched the sciatic nerve It seems to me that the true explanation is that there is a direct leverage applied to the sacro-iliac joint, because with the leg held straight, the ham-string muscles running from the ischium to the head of the tibia pull directly on the joint I have never been able to convince myself that anatomically the nerve is stretched by this procedure, and I believe it to be a fallacy handed down from one book to another In the severe cases it often is not possible to raise the leg in this position 6 inches from the table and this cannot actually stretch the nerve, while it will pull on a sensitive joint With the patient lying face downward, hyperextension of the thigh, which pulls on the sacro-iliac joint in the opposite direction, will often cause sciatic pain, and this certainly cannot pull on the nerve

These two tests, this so-called straight leg raising and the hyperextension of the thighs, are the two most delicate tests that affect the motions of the sacro-iliac joint It has long been recognized that in cases of sciatica Kernig's test is very apt to be positive, but the interpretation has always been referred to the effect on the nerve and very little mention has been made of its action in causing motion of any joint

One of the chief symptoms of a lesion about a joint is deformity which arises whenever the lesion is of any intensity In the knee-joint the deformity is flexion and in the hip-joint it is flexion and adduction, as a rule So that when we see deformity we naturally look for a joint lesion In sciatica it is very common to notice a change from the normal position of the lower portion of the spine This listing or deviation from the normal position is due to either muscular spasm or joint spasm, in the acute cases, or to permanent changes in the joint, in the more chronic cases It is simply what happens in the course of any joint trouble and is commonly seen in the more severe or acute cases If the listing persists we have what is commonly called sciatic scoliosis, that is, simply a deviation or a deformity of the spine due to some joint lesion

Much has been written, especially in the German language, about sciatic scoliosis, but it seems to me that it is simply a symptom and not a distinct condition by itself For the purposes of this paper I shall not go farther into this symptom, but simply draw attention to the fact that it is indicative of joint lesion

The Roentgen-ray should be used in the examination of many cases of sciatica, the same as would be done in any joint case, to show whether there is any bone lesion that is the cause of the symptoms Tuberculosis of the fifth lumbar vertebra is often treated for sciatica for months, because we are content to consider the latter as a disease Hypertrophic arthritis, or ostearthritis of the spine, often has sciatic pain as its chief symptom Also a careful Roentgen-ray study may show why the joints of the lower spine are subject to chronic strains, because we find that the fifth lumbar vertebra is very apt to show certain changes from the normal, such as extra long transverse processes

It is not the purpose of this paper to deal with any minute point in the etiology, or to go into detail in regard to any case, but I shall try to show in the analysis of these cases that a joint in the physical examination shows a lesion and the treatment is based on this fact Also I shall not discuss whether in any individual case there may be a dislocation or subluxation of the sacro-iliac joint, which has lately been under discussion, but shall call those cases in which this diagnosis might be possible acute joint strain, a term which is broad enough to cover the subject Nor shall I try to differentiate whether the lesion may be of the sacro-iliac joint or of the lower lumbar joints, because a disturbance of any of these may cause sciatic pain

Of this series of fifty cases of so-called sciatica, forty-nine showed a definite evidence of a lesion of one of the joints of the lower spine, which include the lumbar articulations, the lumbosacral joint and the sacro-iliac joints Also there is definite evidence that the lesion of the spine has a direct connection with the pain in the sciatic nerve, as is shown by an increase in the pain when there is an attempt at motion of the joint involved One case out of fifty showed no evidence of a spinal lesion, but presented the characteristic evidence of carcinoma of the prostate This case is included and helps to emphasize the point that there is always a definite cause at the origin of the nerve and not a perineuritis along the course of the nerve

There are seventeen cases out of fifty which I have classified as acute strain of the lower spine Most of these represent an acute lesion of one of the sacro-iliac joints, the sciatic symptoms sometimes coming on acutely secondarily to a chronic or recurrent strain of this joint Two of these patients were first examined after having had severe sciatic pain for over a month, when they presented a sacro-iliac joint so sensitive that the slightest pressure caused intense sciatic as well as joint pain And yet the patients told me that this was the first time that any one had ever examined the back This is so because we have been taught to accept the term sciatica as a clinical entity, and that there was no need of examining further

There were twenty-one cases out of fifty that are classified as chronic strain of the lower portion of the spine It is more difficult in this group to connect the sciatic pain with the spinal condition, because the history is often misleading and sometimes shows no direct connection But in every one of these cases there was definite evidence of a joint lesion, as shown by loss of motion and pain on motion, and it was possible to demonstrate an increase of sciatic pain when the affected joint was moved It is in this group that we see the so-called sciatic scoliosis, which is perfect evidence of a joint lesion It is not rational to explain the scoliosis as secondary to the sciatica when they are both symptoms of a joint lesion

The third group is classified as hypertrophic arthritis, the diagnosis being based on the fact that the Roentgen-ray shows definite overgrowth of bone in the region of the lower lumbar spine, which corresponds to the facts as shown on physical examination In this group there were eight cases out of fifty It is not necessary to discuss this group, because all the textbooks recognize that definite spinal lesions may cause sciatic pain

The last group, four out of fifty cases, were proved cases of tuberculosis of the lower spine in adults It is of interest to note that two of these four patients were treated for a year for idiopathic sciatica, and the diagnosis was mistaken because some one was satisfied with the accepted theories It would have been easy to detect a joint lesion as soon as the sciatic pain commenced in these cases, even if it were not possible to diagnose the character of the bone lesion, because there must have been evidences of joint trouble previous to the involvement of the nerve

It is not the presumption that the only cause of sciatic pain is a joint lesion, but on the basis of these cases it is evident that the joint lesion is very frequently overlooked and its importance not recognized Of course, it is perfectly irrational to treat the resulting pain, which is advocated in numerous textbooks and current literature, when the trouble lies in the spine Nobody would think of treating the sciatic pain after he recognizes a tuberculosis of the spine, and therefore the sciatica should not be treated as such when there is definite evidence of a joint strain, which can certainly cause sciatic pain

The conclusions from this study are two

First, there is no clinical entity which is commonly called idiopathic sciatica The evidence is very strong that the accepted theory of a perineuritis due to some inflammatory condition of the nerve sheath is not proved, and that there is always a definite cause at the origin of the nerve The most common cause of sciatic pain is a definite joint lesion

Second, if we have to use the term sciatica, and we undoubtedly will, then it should be a part of the orthopedic teaching One of the chief reasons why there is so much confusion is because it is not well taught, and our knowledge is gathered chiefly from textbooks It should be in the orthopedic textbooks

483 Beacon Street

ABSTRACT OF DISCUSSION

Dr Leonard W Ely, San Francisco I teach my students that there is no such disease entity as sciatica Sciatica means pain in the sciatic nerve, a symptom, not a disease Then they go to other departments, and find that it is treated as a clinical entity, by means of electricity, massage and drugs In almost every case, however, a cause for the pain can be found When we cannot find a cause, we acknowledge our ignorance, and do not attempt to hide it by calling a symptom a disease It is high time that sciatica and intercostal neuralgia followed belly-ache' and 'acute bilious attacks" as diagnoses into the scrap heap

Dr Melvin S Henderson, Rochester, Minn I heartily agree with what Dr Rogers said, and partly with what Dr Ely said I believe, however, that there is a definite group of cases in which you cannot find any cause for so-called sciatica What are you going to do with these cases? I try to locate the cause, but sometimes cannot do it, and should like to know whether any one else can do so always Occasionally I have found that the injection of saline solution cured a small percentage I try it in that particular group just mentioned, after I have tried out all other methods The occasional cure secured seems to me to justify the procedure, as it is devoid of danger if carried out according to the method of Patrick

Dr Joel E Goldthwait, Boston It might be a matter of interest from the point of view of history to know that at the Massachusetts General Hospital, a number of years ago, these patients were sent to the orthopedic department, not at the request of the orthopedic surgeon but of the neurologist who said that eight out of ten of these patients belonged to the orthopedic department, and it was not worth while for them to be sent to the neurologic department first, only to be referred elsewhere He thought it better for the orthopedic department to have to send two patients to the neurologic department than for the neurologic department to have to refer eight to the orthopedic That was the attitude of the neurologist years ago These requests came from the neurologists themselves, and I am under the impression that a smaller proportion of the total number of these patients would now be claimed by the neurologists than at that time

Dr Roland Meisenbach, Buffalo I must agree with Dr Rogers I was very glad to hear him speak of sciatica as a symptom I am willing to acknowledge that there is such a condition as sciatica, but I wish to emphasize that it is rare, that when we have sciatica in any way present, it is usually present as a symptom, due to some other cause than sciatic nerve inflammation One of the best illustrations of this is the sciatica in cases of hypertrophic arthritis, in which the lumen through which the sacral nerves pass gradually became smaller due to the hypertrophic pressure Loose pelvic joints are frequently the cause Sacro-lumbar, or even lumbro-lumbar joints may have a direct bearing on the symptoms of sciatica We must not forget our anatomy and the relation of the lumbar plexus to the sciatic nerve and to the spine I do not believe that the injection of saline into the sciatic nerve would permanently relieve cases in which the sciatica may be the chief symptom, but in which there are other conditions, as a loose sacro-iliac or a disturbed sacro-lumbar joint present However, the injection of novocain may temporarily relieve the patient, but the symptoms will recur Whenever we see a case of sciatica, it is our duty to search for the cause, and not treat the symptom

Dr John Ridlon, Chicago I have had the pleasure of having to be a month in bed for this kind of pain at least ten times I have not had Pott's disease, or osteoarthritis of the lumbar spine, or a slipped sacro-iliac joint, so the pain was not due to any of these I think that this shifting of the name of sciatica to a strained sacro-iliac joint is not by any means clearing up the question of painful backs

Dr John Prentiss Lord, Omaha I agree with the majority here that mechanical causes are back of a large proportion of these cases, but I have found that we must consider the patients as individuals the same as we consider those who have pains elsewhere Some of these pains are toxic The mechanical condition is not the only one present The patients are frequently anemic Some do not eliminate properly In one notable case in Omaha, the patient had tried all methods of cure, liquid paraffin relieved his intestinal stasis, and as soon as elimination was properly established, his pain disappeared I think that we must not forget that we are not merely manipulators, but are still doctors We must recognize the fact that some patients need treatment besides the particular treatment that comes under our specialty I believe that in some cases in which the pain is inexplicable and you cannot find a cause for it, if you treat the patient in a sensible way recovery may be expected

Dr Frederick C Test, Chicago I differ with Dr Rogers only in regard to the percentages of the causes that he stated for this pain In my experience, which comprises approximately fifty cases of distinct pain referred to the lumbosacral region, I have not been satisfied that I have had many loose sacral joints I found that I had to look for the cause higher up, and have almost always discovered an elongated transverse process of the fifth lumbar vertebra Sometimes this is present on only one side, but very frequently on both, perhaps associated with tilting of the lower spine and generally with stiffness, with pain usually shooting down one sciatic nerve or the other In such cases, I occasionally find that there will be relief obtained by manipulation, either intentional or, as in two or three cases, the result of some movement on the part of the patient that seemed to free the transverse process and so relieve the pressure—temporarily, at any rate, and sometimes permanently—on the nerve roots I remember a case in which there was pain in the lower back and extending down the right leg, and in which the roentgenogram showed a decidedly elongated transverse process on each side of the fifth lumbar vertebra Operation was declined for the time being, and afterward, while lifting a pail of water from the floor, the patient felt a twist on the right side of the back, and the pain immediately left the right sciatic nerve, and temporarily went to the left It has since gone from the left sciatic nerve, and she is now free from pain Regarding the other causes that cannot be traced to a bony lesion, I personally feel that there is something, at any rate, in the matter of a toxemic neuritis from a focus of infection somewhere in the body I remember one case in which I was particularly interested in which pain in the sciatic nerve came on three days after a nose operation After the nose condition cleared up, the sciatica gradually disappeared, but has a tendency to return whenever there is a coryza

Dr J D Griffith, Kansas City, Mo I am treating now two patients in whom there is a marked sciatica recurring every now and then I think that there are other causes for sciatica, in addition to the one that Dr Rogers pointed out, in a number of cases My cases belong distinctly to the type of enteroptosis There was an enormously dilated and enlarged sigmoid, and the paresthesia, etc, followed whenever it was *loaded* I have *found* relief by instituting hyperextension, prone hanging and the corset

Dr Frank E Peckham, Providence, R I I think Dr Rogers' idea was to trace the sciatica to the sacro iliac joint Of course the joint is affected by trouble in still other regions, and you may get a toxic case, as described by Dr Lord, with a real subluxation, as Dr Ryerson probably has just described I had two such cases, one was reduced under ether, presumably a subluxation, and the patient was well afterward and remained so The other case was one of pain in the groin, which I have seen in quite a few cases One manipulation without ether practically cured him, but these are unusual cases As Dr Lord says, we must study the patient Although he has local symptoms, his trouble may be quite general Another patient after many trials was cured by arch supports There was a static strain, which is a condition we must consider There are times when the ligaments require toning up and stimulating, which I do by various physicotherapeutic measures I know of one case in a doctor who had recurrent attacks By doing gymnastics morning and night, and hyperextending himself in bed, he has been clear of an attack for some time. I think that Dr Rogers is correct in tracing the pain to the sacro-iliac joint, but this joint itself is affected by various infections, and we should look for, and treat these

Dr James T Watkins, San Francisco Dr Lord said that occasionally sciatica is of toxic origin In confirmation of this contention, I should like to report a case I saw The gentleman, an athletic person, had had recurrent attacks of sciatica for a long time For four years he had been going the rounds of the physicians In his youth he had had gonorrhea and was now obsessed with the idea that this was the cause of his trouble, despite the fact that the best genito-urinary men had found nothing wrong I pointed out to him that nothing could be gained by duplicating the work which had been done by the exceedingly competent men who had preceded me in his case We therefore undertook a new departure and had his mouth roentgenographed My dentist friends advise me that there is no such thing as a healthy adult mouth This man had pyorrhea and alveolar abscesses I sent him to Dr T Sidney Smith Dr Smith advised certain work and that one tooth be extracted This displeased the patient, so he consulted a dentist who had been recommended to him at his club This man failed to relieve him He ultimately returned to me and I sent him back to Dr Smith Then he had the tooth extracted Prior to this he had attacks of sciatica every two or three weeks Since removing the tooth and having his mouth treated efficiently an interval of some months has elapsed during which he has had no sciatica at all

Dr Albert H Freiberg, Cincinnati We must remember that a man has two sciatic nerves, and also many other nerves Therefore, there is to be explained why a man happens to have a pain in one sciatic nerve However much there may be a constitutional cause, either in the shape of infection or some constitutional disease, such as diabetes, it is only reasonable to suppose that there is a localizing factor to be found, if we only know where to look for it Since we have been able, by modern methods and investigations, to study better the conditions of the spine, and the pelvic joints, and since we know the relationships of sacrolumbar cord and sacrolumbar plexuses, we have eliminated a large percentage of the unexplained cases We are called on in every case to tell why the individual has the pain in his right or left sacro-iliac region or his right or left sciatic nerve I do not mean to say that I am always able to tell, any more than any one else I can give the case a careful analysis by means of the Roentgen ray and other diagnostic helps, but I think that even in those cases in which we are unable to find the localizing factor, we must, nevertheless, assume that there is one that we should probably find with increase of knowledge We must strive to explain, in every case that comes to us, why the individual has a pain in the sciatic nerve, and not somewhere else

Dr Reginald H Sayre, New York We have been over almost all parts of the body, looking for the cause of pain in the sciatic nerve, but no one has mentioned the necessity of looking for fissures in the rectum, for carcinomas, for retroverted uteri, for prolapsed ovaries and dilated colons Anything resting on the sciatic nerve and hurting it or the sacral plexus may cause this pain

Dr Arthur Lawrence Fisher, San Francisco I should like to emphasize a point in regard to the mechanism of the pain We are taught that it is due to pressure Unquestionably, in some cases, it is due to pressure on the nerve, but in others, there is a reflex from the joint, just as the pain in hip-joint disease is referred to the knee The nerve which enervates the joint comes from the same segments of the cord as the nerve along which the pain is referred, which in this instance is in the sciatic nerve

Dr Mark Homer Rogers, Boston The chief point to which I wish to call attention is that the lesion is somewhere near the origin of the nerve, and not along the course of the nerve, as is commonly taught I did not intend to lay stress on the importance of any one joint, namely the sacro-iliac It is not any one joint but any part of the lower spine from which the nerve arises that is the primary cause If you will examine the spine you will find a spinal lesion in a majority of cases The strongest point that I have made is the fact that the neurologic department of the Massachusetts General Hospital has no record of a true case of sciatica in the last six months, whereas formerly they had many hundreds

---

Disease Not a Respecter of States' Rights—The greatest asset which our country can have is the healthy American citizen, and, valuable as it may be to increase the health of live-stock and vegetation, it is of far greater importance that we throw every possible safeguard about the health of the man who is responsible for that live stock and vegetation The argument has been advanced that since the States at the time of their entry into the Union reserved to themselves their police powers and since the administration of health is one of the police powers, that the states should themselves grapple with their own health problems and conquer them, and that it is therefore improper for the federal government to make appropriations the application of which will react to the health of states This argument is fallacious in the extreme As I have previously pointed out, this problem is not a purely intrastate problem Milk which is produced under insanitary conditions in New Jersey may produce an epidemic in New York Butter or cheese which is made under insanitary conditions or from polluted milk in Wisconsin or Illinois may produce disease in Virginia or the District of Columbia Lettuce or watercress which is grown in soil which is polluted with human excrement may be shipped in refrigerator cars to a distant point and there produce an epidemic of typhoid fever The man who contracts typhoid fever on a farm in Texas may become a chronic typhoid bacillus carrier and distribute the disease wherever he goes no matter what the state or what the city Disease has absolutely no regard for state lines whatsoever Disease is equally uninterested in states' rights Sewage poured into a river in one state is easily carried by that stream to another state So I say to you that the problem of rural sanitation is not a local problem but one which concerns the health and the physical integrity of our entire nation—Senator Joseph E Ransdell, of Louisiana, in the U S Senate, July 14, 1916

A REPORT ON THE TREATMENT OF PERNICIOUS ANEMIA BY TRANSFUSION AND SPLENECTOMY *

H Z GIFFIN, M D
ROCHESTER, MINN

It* is difficult to appreciate the fact that pernicious anemia is at present an incurable and fatal disease which in some respects is more to be dreaded than cancer Its relapses, remissions, and merciless progressive course impress on us the necessity for a universal study of its manifestations A thorough trial of splenectomy in the treatment of pernicious anemia is therefore warranted, though a consideration of the results is at present necessarily confused by fallacies and insufficient data There is so far no evidence that splenectomy has cured pernicious anemia, but there are definite indications of consistent temporary improvement in a majority of instances

Our early experience with splenectomy for pernicious anemia was discouraging During the past two years, however, it has become evident that a marked reaction and a consistent temporary gain, at least for a period of months, follows splenectomy in selected cases, and surgical treatment has been more frequently suggested after a frank explanation to the patients concerning the course of the disease, the inadequacy of present methods of treatment, and the experimental nature of the procedure

In February, 1910, the spleen was removed from a patient (A7040) who suffered from severe attacks of epistaxis and had a very large spleen, an icteroid tinge, and a blood picture of pernicious anemia including the presence of megaloblasts Splenectomy was advised not with the specific idea of applying that treatment to pernicious anemia but largely because of the great size of the spleen and the somewhat indefinite characteristics of the blood picture The patient did not report himself as improved, and died three years after operation with pneumonia

Experience may show that cases of this type, in which there is a very large spleen, a hemolytic type of anemia, and a blood picture of pernicious anemia would better be grouped separately, as suggested by Moffitt,[1] but they cannot at present be omitted from consideration in a study of this character

The remaining patients of this series were operated on between Aug 1, 1914, and April 1, 1916 The records extended up to June 1, 1916, from twenty-three months to three months following operation, most of them, however, were for periods of less than one year

Preoperative Transfusion—Preoperative transfusion has been done in nineteen cases, from one to four transfusions having been given in each instance A marked gain followed transfusion in eight cases Very rapid and decided gains were seen in two patients In one the hemoglobin rose from 10 to 40 per cent, with a gain of 2,000,000 red cells in one month, in the other the hemoglobin rose from 16 to 59 per cent, with a gain of 1,500,000 red cells in one month Each of these patients received two transfusions In six there were gains of only a few points, and in four there was no definite improvement In one the hemoglobin per-to refer eight to the orthopedic That was the attitude of the neurologist years ago These requests came from the neurologists themselves, and I am under the impression that a smaller proportion of the total number of these patients would now be claimed by the neurologists than at that time

[1] Moffitt H C Studies in Pernicious Anemia Am Jour Med Sc 1914, 148, 817

Dr Roland Meisenbach, Buffalo I must agree with Dr Rogers I was very glad to hear him speak of sciatica as a symptom I am willing to acknowledge that there is such a condition as sciatica, but I wish to emphasize that it is rare, that when we have sciatica in any way present, it is usually present as a symptom, due to some other cause than sciatic nerve inflammation One of the best illustrations of this is the sciatica in cases of hypertrophic arthritis, in which the lumen through which the sacral nerves pass gradually became smaller due to the hypertrophic pressure Loose pelvic joints are frequently the cause Sacro-lumbar, or even lumbrolumbar joints may have a direct bearing on the symptoms of sciatica We must not forget our anatomy and the relation of the lumbar plexus to the sciatic nerve and to the spine I do not believe that the injection of saline into the sciatic nerve would permanently relieve cases in which the sciatica may be the chief symptom, but in which there are other conditions, as a loose sacro-iliac or a disturbed sacro-lumbar joint present However, the injection of novocain may temporarily relieve the patient, but the symptoms will recur Whenever we see a case of sciatica, it is our duty to search for the cause, and not treat the symptom

Dr John Ridlon, Chicago I have had the pleasure of having to be a month in bed for this kind of pain at least ten times I have not had Pott's disease, or ostearthritis of the lumbar spine, or a slipped sacro-iliac joint, so the pain was not due to any of these I think that this shifting of the name of sciatica to a strained sacro-iliac joint is not by any means clearing up the question of painful backs

Dr John Prentiss Lord, Omaha I agree with the majority here that mechanical causes are back of a large proportion of these cases, but I have found that we must consider the patients as individuals the same as we consider those who have pains elsewhere Some of these pains are toxic The mechanical condition is not the only one present The patients are frequently anemic Some do not eliminate properly In one notable case in Omaha, the patient had tried all methods of cure, liquid paraffin relieved his intestinal stasis, and as soon as elimination was properly established, his pain disappeared I think that we must not forget that we are not merely manipulators, but are still doctors We must recognize the fact that some patients need treatment besides the particular treatment that comes under our specialty I believe that in some cases in which the pain is inexplicable and you cannot find a cause for it, if you treat the patient in a sensible way recovery may be expected

Dr Frederick C Test Chicago I differ with Dr Rogers only in regard to the percentages of the causes that he stated for this pain In my experience, which comprises approximately fifty cases of distinct pain referred to the lumbosacral region, I have not been satisfied that I have had many loose sacral joints I found that I had to look for the cause higher up, and have almost always discovered an elongated transverse process of the fifth lumbar vertebra Sometimes this is present on only one side, but very frequently on both, perhaps associated with tilting of the lower spine and generally with stiffness, with pain usually shooting down one sciatic nerve or the other In such cases, I occasionally find that there will be relief obtained by manipulation, either intentional or, as in two or three cases, the result of some movement on the part of the patient that seemed to free the transverse process and so relieve the pressure—temporarily, at any rate, and sometimes permanently—on the nerve roots I remember a case in which there was pain in the lower back and extending down the right leg, and in which the roentgenogram showed a decidedly elongated transverse process on each side of the fifth lumbar vertebra Operation was declined for the time being, and afterward, while lifting a pail of water from the floor, the patient felt a twist on the right side of the back, and the pain immediately left the right sciatic nerve, and temporarily went to the left It has since gone from the left sciatic nerve, and she is now free from pain Regarding the other causes that cannot be traced to a bony lesion, I personally feel that there is something, at any rate, in the matter of a toxemic neuritis from a focus of infection somewhere in the body I remember one case in which I was particularly interested in which pain in the sciatic nerve came on three days after a nose operation After the nose condition cleared up, the sciatica gradually disappeared, but has a tendency to return whenever there is a coryza

Dr J D Griffith, Kansas City, Mo I am treating now two patients in whom there is a marked sciatica recurring every now and then I think that there are other causes for sciatica, in addition to the one that Dr Rogers pointed out, in a number of cases My cases belong distinctly to the type of enteroptosis There was an enormously dilated and enlarged sigmoid, and the paresthesia, etc, followed whenever it was loaded I have found relief by instituting hyperextension, prone hanging and the corset

Dr Frank E Peckham, Providence, R I I think Dr Rogers' idea was to trace the sciatica to the sacro iliac joint Of course the joint is affected by trouble in still other regions, and you may get a toxic case, as described by Dr Lord, with a real subluxation, as Dr Ryerson probably has just described I had two such cases, one was reduced under ether, presumably a subluxation, and the patient was well afterward and remained so The other case was one of pain in the groin, which I have seen in quite a few cases One manipulation without ether practically cured him, but these are unusual cases As Dr Lord says, we must study the patient Although he has local symptoms, his trouble may be quite general Another patient after many trials was cured by arch supports There was a static strain, which is a condition we must consider There are times when the ligaments require toning up and stimulating, which I do by various physicotherapeutic measures I know of one case in a doctor who had recurrent attacks By doing gymnastics morning and night, and hyperextending himself in bed, he has been clear of an attack for some time I think that Dr Rogers is correct in tracing the pain to the sacro-iliac joint, but this joint itself is affected by various infections, and we should look for, and treat these

Dr James T Watkins, San Francisco Dr Lord said that occasionally sciatica is of toxic origin In confirmation of this contention, I should like to report a case I saw The gentleman, an athletic person, had had recurrent attacks of sciatica for a long time For four years he had been going the rounds of the physicians In his youth he had had gonorrhea and was now obsessed with the idea that this was the cause of his trouble, despite the fact that the best genito-urinary men had found nothing wrong I pointed out to him that nothing could be gained by duplicating the work which had been done by the exceedingly competent men who had preceded me in his case We therefore undertook a new departure and had his mouth roentgenographed My dentist friends advise me that there is no such thing as a healthy adult mouth This man had pyorrhea and alveolar abscesses I sent him to Dr T Sidney Smith Dr Smith advised certain work and that one tooth be extracted This displeased the patient, so he consulted a dentist who had been recommended to him at his club This man failed to relieve him He ultimately returned to me and I sent him back to Dr Smith Then he had the tooth extracted Prior to this he had attacks of sciatica every two or three weeks Since removing the tooth and having his mouth treated efficiently an interval of some months has elapsed during which he has had no sciatica at all

Dr Albert H Freiberg, Cincinnati We must remember that a man has two sciatic nerves, and also many other nerves Therefore, there is to be explained why a man happens to have a pain in one sciatic nerve However much there may be a constitutional cause, either in the shape of infection or some constitutional disease, such as diabetes, it is only reasonable to suppose that there is a localizing factor to be found, if we only know where to look for it Since we have been able, by modern methods and investigations, to study better the conditions of the spine, and the pelvic joints, and since we know the relationships of sacrolumbar cord and sacrolumbar plexuses, we have eliminated a large percentage of the unexplained cases We are called on in every case to tell why the individual has the pain in his right or left sacro-iliac region or his right or left sciatic nerve I do not mean to say that I am always able to tell, any more than any one else I can give the case a careful analysis by means of the Roentgen ray and other diagnostic helps, but I think that even in those cases in which we are unable to find the localizing factor, we must, nevertheless, assume that there is one that we should probably find with increase of knowledge We must strive to explain, in every case that comes to us, why the individual has a pain in the sciatic nerve, and not somewhere else

Dr Reginald H Sayre, New York We have been over almost all parts of the body, looking for the cause of pain in the sciatic nerve, but no one has mentioned the necessity of looking for fissures in the rectum, for carcinomas, for retroverted uteri, for prolapsed ovaries and dilated colons Anything resting on the sciatic nerve and hurting it or the sacral plexus may cause this pain

Dr Arthur Lawrence Fisher, San Francisco I should like to emphasize a point in regard to the mechanism of the pain We are taught that it is due to pressure Unquestionably, in some cases, it is due to pressure on the nerve, but in others, there is a reflex from the joint, just as the pain in hip-joint disease is referred to the knee The nerve which enervates the joint comes from the same segments of the cord as the nerve along which the pain is referred, which in this instance is in the sciatic nerve

Dr Mark Homer Rogers, Boston The chief point to which I wish to call attention is that the lesion is somewhere near the origin of the nerve, and not along the course of the nerve, as is commonly taught I did not intend to lay stress on the importance of any one joint, namely the sacro iliac It is not any one joint but any part of the lower spine from which the nerve arises that is the primary cause If you will examine the spine you will find a spinal lesion in a majority of cases The strongest point that I have made is the fact that the neurologic department of the Massachusetts General Hospital has no record of a true case of sciatica in the last six months, whereas formerly they had many hundreds

Disease Not a Respecter of States' Rights—The greatest asset which our country can have is the healthy American citizen, and, valuable as it may be to increase the health of live-stock and vegetation, it is of far greater importance that we throw every possible safeguard about the health of the man who is responsible for that live stock and vegetation The argument has been advanced that since the States at the time of their entry into the Union reserved to themselves their police powers and since the administration of health is one of the police powers, that the states should themselves grapple with their own health problems and conquer them, and that it is therefore improper for the federal government to make appropriations the application of which will react to the health of states This argument is fallacious in the extreme As I have previously pointed out, this problem is not a purely intrastate problem Milk which is produced under insanitary conditions in New Jersey may produce an epidemic in New York Butter or cheese which is made under insanitary conditions or from polluted milk in Wisconsin or Illinois may produce disease in Virginia or the District of Columbia Lettuce or watercress which is grown in soil which is polluted with human excrement may be shipped in refrigerator cars to a distant point and there produce an epidemic of typhoid fever The man who contracts typhoid fever on a farm in Texas may become a chronic typhoid bacillus carrier and distribute the disease wherever he goes no matter what the state or what the city Disease has absolutely no regard for state lines whatsoever Disease is equally uninterested in states' rights Sewage poured into a river in one state is easily carried by that stream to another state So I say to you that the problem of rural sanitation is not a local problem but one which concerns the health and the physical integrity of our entire nation—Senator Joseph E Ransdell, of Louisiana, in the U S Senate, July 14, 1916

A REPORT ON THE TREATMENT OF PERNICIOUS ANEMIA BY TRANSFUSION AND SPLENECTOMY *

H Z GIFFIN, M D
ROCHESTER, MINN

It is difficult to appreciate the fact that pernicious anemia is at present an incurable and fatal disease which in some respects is more to be dreaded than cancer Its relapses, remissions, and merciless progressive course impress on us the necessity for a universal study of its manifestations A thorough trial of splenectomy in the treatment of pernicious anemia is therefore warranted, though a consideration of the results is at present necessarily confused by fallacies and insufficient data There is so far no evidence that splenectomy has cured pernicious anemia, but there are definite indications of consistent temporary improvement in a majority of instances

Our early experience with splenectomy for pernicious anemia was discouraging During the past two years, however, it has become evident that a marked reaction and a consistent temporary gain, at least for a period of months, follows splenectomy in selected cases, and surgical treatment has been more frequently suggested after a frank explanation to the patients concerning the course of the disease, the inadequacy of present methods of treatment, and the experimental nature of the procedure

In February, 1910, the spleen was removed from a patient (A7040) who suffered from severe attacks of epistaxis and had a very large spleen, an icteroid tinge, and a blood picture of pernicious anemia including the presence of megaloblasts Splenectomy was advised not with the specific idea of applying that treatment to pernicious anemia but largely because of the great size of the spleen and the somewhat indefinite characteristics of the blood picture The patient did not report himself as improved, and died three years after operation with pneumonia

Experience may show that cases of this type, in which there is a very large spleen, a hemolytic type of anemia, and a blood picture of pernicious anemia would better be grouped separately, as suggested by Moffitt,[1] but they cannot at present be omitted from consideration in a study of this character

The remaining patients of this series were operated on between Aug 1, 1914, and April 1, 1916 The records extended up to June 1, 1916, from twenty-three months to three months following operation, most of them, however, were for periods of less than one year

Preoperative Transfusion—Preoperative transfusion has been done in nineteen cases, from one to four transfusions having been given in each instance A marked gain followed transfusion in eight cases Very rapid and decided gains were seen in two patients In one the hemoglobin rose from 10 to 40 per cent, with a gain of 2,000,000 red cells in one month, in the other the hemoglobin rose from 16 to 59 per cent, with a gain of 1,500,000 red cells in one month Each of these patients received two transfusions In six there were gains of only a few points, and in four there was no definite improvement In one the hemoglobin percentage and erythrocyte count fell, but later, after *splenectomy, improvement occurred.*

* From the Mayo Clinic

* Presented before the Association of American Physicians, May 10 1916 Washington D C

[1] Moffitt H C Studies in Pernicious Anemia Am Jour Med Sc 1914, 148, 817

In general, preoperative transfusions have proved valuable in improving the general condition of the patient and in favorably affecting the blood picture. The hemoglobin percentage and the red cell count have been moderately raised and the characteristics of the blood count favorably affected. Our knowledge of the hemopoietic system indicates that a consistently low leukocyte count with relative and absolute reduction in polymorphonuclear cells is to be interpreted as the result of severe injury to the bone marrow. Transfusion is usually followed by a gradual slight rise in the leukocyte count and an increase in the absolute number of polymorphonuclear cells. This reaction is not, however, to be compared in degree with that following splenectomy, which, on the other hand, must be considered in the light of postoperative leukocytosis in general.

TABLE 1.—SPLENECTOMY FOR PERNICIOUS ANEMIA

	Cases
Total (April 1, 1916)	31
Operative deaths (9.7%)	3
Recovered from operation	28
Marked and continuous gain after splenectomy during the first 3 mo. period	22
Number of cases recorded during second 3 mo. period	16
Number of cases maintaining gain during second 3 mo. period	11
Relapse	8
Postoperative deaths	5

Splenectomy.—That definite benefit for a period of months follows splenectomy in a high percentage of cases seems to be clearly indicated by a study of this series. Of twenty-eight patients recovering from operation, there was a gain during the first period of three months in twenty-two (78 per cent.). During the second period of three months, eleven (68 per cent.) of sixteen patients then living maintained their gain. This gain represents a satisfactory, and in several instances, a remarkable, improvement in the blood picture and the general condition. It has, however, little relationship to spinal cord symptoms or signs. Two living patients have maintained a satisfactory condition for one year, three for nine months and three for six months (Tables 1 and 2).

In the course of pernicious anemia, splenectomy seems to cause a more profound immediate reaction than any other form of treatment. This is demonstrated by our observations chiefly in three ways: (1) by an improvement in the blood picture and a change in its characteristics, (2) by a gain in the general condition, and (3) by a fall in the values of the blood-derived pigments in the duodenal contents.

1. *The Blood Picture.*—The very prompt occurrence of leukocytosis with a corresponding increase in the relative and absolute polymorphonuclear neutrophil count, together with showers of normoblasts, is indicative of a very marked reaction after splenectomy. The average leukocyte count in these cases within a few days of operation was 11,531. A very high polymorphonuclear count was almost constant. This leukocytosis persisted at least for a period of months. One month after operation it averaged 11,473. In cases of which we have record, from three to six months following splenectomy it averaged 10,283. The leukocytosis following splenectomy for pernicious anemia differs *from the leukocytosis following operations in general* both in degree and in persistence. The polymorphonuclear cells, it is agreed, have their origin in the bone marrow, and their increase may be either the result of bone marrow stimulation or of decreased blood destruction. No similar reaction is seen following transfusion.

Large numbers of normoblasts were found in the blood smears in twenty-five cases. The average was fifty-six in a count of 300 leukocytes. This is exclusive of one case in which 536 were recorded.

The gain in hemoglobin was gradual in most cases. The average gain in twenty patients, who showed satisfactory improvement, was from 38 per cent. just preceding splenectomy to 72 per cent. at periods varying from one month to six months following operation. In three patients it reached 90 per cent. or more.

The increase in the erythrocyte count ran parallel to the rise in hemoglobin. The average erythrocyte count in the twenty-two cases showing a gain was 2,000,000 just preceding splenectomy and 3,490,000 at periods varying from one month to six months after operation. In one patient it reached 5,200,000 cells, in seven it rose to over 4,000,000. This improvement was independent of preoperative transfusion, as is evidenced by the fact that nine patients in whom preoperative transfusion was not given showed an average gain of from 1,900,000 to 3,700,000. *On the other hand, the greatest average gain* was seen in thirteen patients as a result of combined preoperative transfusion and splenectomy—an average gain from 1,200,000 to 3,500,000. Postoperative transfusion has been given only in relapses, and not as a routine procedure.

It seems to be clear, therefore, that the blood picture is more decidedly and consistently influenced by splenectomy than by any other method of treatment. It has not yet been shown that this improvement is

† Death 3 years.

more than temporary. A polymorphonuclear increase which persists for months, great numbers of normoblasts, and a gradual rise in the hemoglobin and the red cell count are most prominent.

2. *The General Condition.*—An improvement in appetite and in general strength has been noted during the early weeks following splenectomy. This has been recorded even before any decided improvement in the blood has taken place. The patients seemed to be less toxic. All but two promptly lost their icteroid tinge. Elimination or partial elimination of some product of altered metabolism or hemolysis would explain the change in the general condition. The psychic effect of surgical treatment has been minimized by a previous explanation of our incomplete knowledge concerning the results.

3. *The Fall in the Values of the Blood-Derived Pigments in the Duodenal Contents.*—The increase of urobilin in stools of patients suffering with hemolytic types of anemia and its marked decrease after splenectomy have been demonstrated by Eppinger[2] and his co-workers. The clinical importance of the estimation of urobilin in the excretions in various types of anemia is shown by the work of Wilbur and Addis.[3] The quantitative estimation of urobilin and urobilinogen spectroscopically in Wilbur and Addis units has been successfully applied to the duodenal contents by Schneider.[4] We have estimated the values of the blood-derived pigments in the duodenal contents of thirty-four patients, and our findings in general corroborate those of Schneider. The only results I report at this time were obtained in nine cases of this series. The very striking fall in the values of the blood-derived pigments after splenectomy would seem to indicate a favorable effect with respect to the hemolytic factor. The values frequently run parallel to the degree of icterus (Table 3). In one case the total estimation of urobilin and urobilinogen fell from 6,000 units before operation to 800, twenty-one days afterward, in another from 5,000 units to 200 units. That this marked reduction in bilirubin, urobilin and urobilinogen in the duodenal contents will prove constant is likely, that it will obtain at a later period, after splenectomy, we have yet no indication.

Can we formulate what might be termed a balance between the hemolytic and myelotoxic factors in a given case? Between blood destruction and blood production? The values for the blood-derived pigments, it would seem, should in some measure be an index of hemolysis; on the other hand, the characteristics of the blood picture, if we can properly interpret them, are doubtless expressive of the condition of the bone marrow. Decided fluctuations in the leukocyte count and in the characteristics of the differential count are seen in many cases of this series, both before and after transfusion, and before and after splenectomy. There is considerable evidence to indicate, however, that a consistently low leukocyte count with a reduction of the polymorphonuclear neutrophils is indicative of severe bone marrow insufficiency. Certainly a constant complete inversion of polymorphonuclear and lymphocyte percentages, that is, a very low polymorphonuclear percentage with a high lymphocyte percentage is an unfavorable indication, though it does not mean that a subsequent remission may not occur. If a patient with high hemolytic values is able, in spite of active hemolysis, to maintain a blood picture with favorable characteristics and only moderate anemia, there should be present an active bone marrow, and the case would appear to be a more favorable one for splenectomy. Irrespective of high or low hemolytic values, if the leukocyte count is consistently low with an inversion of the differential count, and the anemia extreme, showing no reaction after transfusion or medicinal treatment, the case would seem to be an unfavorable one because of probable advanced pathologic change in the bone marrow.

Age.—The largest number of patients (twelve) were between 40 and 50 years of age. One was in the second decade, three in the third, five in the fourth, eight in the sixth, and two in the seventh.

The progress of the patient in its relationship to age cannot at present be ascertained from a study of these cases. In general, the older patients presented less evidence of active hemolysis and more evidence of marrow damage. The patients of middle age were of both the hemolytic and myelotoxic types, while in younger patients hemolysis was usually active. The severity of the disease varied with the individual case irrespective of age, save that the oldest patients were prone to a chronic form with less definite remissions. While the younger patients probably are capable of more benefit as a result of bone marrow stimulation and an amelioration of the hemolytic factor, many patients of the fourth and fifth decades have shown remarkable gains.

Weight of Spleen.—The average weight of the spleens removed in this series was 422 gm., exclusive of two very large spleens weighing, respectively, 1,120 and 1,600 gm. In only two cases did the spleen weigh less than 175 gm. The very small spleen is usually present in the late stages of pernicious anemia, and a moderately enlarged spleen is generally found when hemolytic activity is marked. Splenectomy influences chiefly the hemolytic factor of the disease, and one might argue that the presence of a moderately enlarged spleen is a point of evidence in favor of splenectomy.

Operative Mortality—In this group of thirty-one cases there were three operative deaths, giving an operative mortality of 9 7 per cent[5] There is no apparent reason why the operative mortality of splenectomy for pernicious anemia should not be low when a proper operative selection has been made The spleen is relatively small, adhesions usually insignificant, and the technical procedures not difficult The risk of surgical treatment is decidedly increased in patients with severe anemia, and every endeavor should be made to improve the hemoglobin to 35 or 40 per cent, and the erythrocyte count to 1,500,000 or 2,000,000 cells

A consideration of the features presented by the three patients who died following operation reveals that one of them was distinctly not a case for surgical treatment The hemoglobin was 19 per cent, even after two transfusions, and a consistently low leukocyte count was present The other two operative deaths were similar in character, and presented unusually striking features The patients died, on the third and fourth days, respectively, after having suddenly developed fever as high as 106 F and delirium, in one case associated with hyperpnea and pulmonary edema, and in the other persistent vomiting with ultimate coma

Postmortem examination in both instances failed to show a sufficient cause for death These fatal attacks may have been the result of operation at a time of recrudescence or impending crisis, in one instance acidosis is a probability Neither of these patients was in a weakened condition before operation, but both of them for two weeks previous to operation showed a falling hemoglobin, a decrease in the red blood cell count, and a low and falling leukocyte count, all of which would at the present time be regarded as points in evidence against a recommendation for surgery

Postoperative Deaths — Five patients In two patients the downward course was not averted by splenectomy, and death occurred at home within three months In one of these patients there was a slight gain in the condition of the blood, but a double femoral thrombophlebitis developed, and the patient died with septic manifestations In the second patient there was no reaction either in the general condition or the blood, and a steady decline occurred The spleen in this instance was very much above the average size for pernicious anemia, weighing 1,120 gm A third patient died at nine months after decided improvement which was maintained for approximately six months A fourth patient died at twelve months after gaining to 90 per cent hemoglobin and 4,000,000 red cells and maintaining a good condition for seven months The fifth patient died three years after splenectomy, his postoperative course was never determined

Relapses—Three living patients have had relapses, two within six months following operation after an improvement during the first period of three months, and one at fourteen months after recovery from a previous relapse at nine months Two of these who were treated by transfusions at the time of relapse have again had remissions Three additional patients have never shown evidence of definite gain since splenectomy

SUMMARY

1 There is no evidence that splenectomy has cured pernicious anemia

2 A review of thirty-one cases of splenectomy for pernicious anemia demonstrates a definite gain in the blood, the weight, and the general condition during the first three months of the postoperative period in 78 per cent of the cases, during the second three months' period, 68 per cent of living patients maintained their gain

3 A consideration of the advisability of splenectomy would seem to be warranted at present chiefly in young and middle-aged patients of good general resistance, who show evidence of active hemolysis and in whom the spleen is moderately enlarged

4 The estimation of the blood-derived pigments in the duodenal contents is valuable in determining the degree of hemolytic activity present at a given time A comparison of the degree of hemolysis with the severity of the anemia would seem to be indicative of the productive power of the bone marrow

5 Preoperative treatment, especially transfusions, should be employed to influence the general condition of the patients and to improve the characteristics of the blood picture The operative risk is increased when the hemoglobin is below 35 per cent and the erythrocyte count less than 1,500,000 cells

6 Postoperative transfusions have not been given as a routine procedure, but transfusions have been successfully employed in postoperative relapse[6]

---

[5] Forty seven splenectomies for pernicious anemia have been done up to Sept 1, 1916 with three operative deaths, an operative mortality of 6 4 per cent There have been no deaths in the last twenty nine cases

THE PHYSICOCHEMISTRY OF THE GONOCOCCUS

IN RELATION TO IMMUNITY AND THERAPEUSIS*

C C WARDEN, MD
Beach Scholar, Hygienic Laboratory, University of Michigan
ANN ARBOR, MICH

In an earlier paper[1] before this section there were submitted arguments, based on experiments, tending to support the conclusion that all forms of serums and vaccines hitherto employed against gonorrhea were without definite dependable value, and apparent reasons for their failure were emphasized Work of the past year tends to confirm these opinions and leads to further generalizations

Starting from the fact that a true and lasting immunity against gonococcus infections is found in all animals and, as a rule, in all tissues of man, save only in certain special tissues, we pass on to observe that unquestionably these receptive tissues in man are occasionally proof against infection, and appear to depend for their immunity, not so much on the presence of antibody, as on the existence of certain physical states within themselves and their fluids But in the present state of our knowledge we cannot hope to obtain an artificial immunity by any biologic method of treatment greater than that afforded by an attack of the disease itself, which, unfortunately, is negligible This statement is true in general of all infectious diseases, diphtheria being a type of exception, but those caused by members of the family of *Coccaceae* are especially apt to be recurrent It is strikingly apparent that an immunity such as may be induced against the *B typhosus* group, for instance, is unknown against the coccus group Unquestionably the reaction between germs and body fluids in the latter is of a somewhat different nature

[1] Warden C C Vaccine Treatment of Gonorrhea The Journal A M A, Dec 11 1915 p 2080

I wish here to summarize my observations on the chemicophysical relations of the gonococcus to fluids in the laboratory and within the body, all of which are concerned as factors in the life of the cocci

The gonococcus is regarded as a cell composed of substances in a colloid state, having an extremely soft, delicate body and limiting surface extraordinarily sensitive to changes of osmotic pressure and surface tension When directly observed microscopically during active growth on artificial medium the cocci never have the appearance observed in smears of gonorrheal exudate, or in smears made after the removal of a colony from the medium, but their contours strongly suggest an ameboid state This deformity in contour is due, however, not to inherent ameboid power of the cocci, but rather to the influence of surroundings The conditions are strikingly similar to those existing in an oil-in-water system, that is, a heavy emulsion of oil in water, where the droplets of oil in dispersion are so closely packed as to assume polyhedral shapes Indeed, the gonococcus is quite comparable to an oily globule The microscope shows also the distortion of contour exerted by the "pull" of such substances as oil, glycerol and sugar solutions

I have shown[2] the gonococcus to contain various chemical substances which constitute an entity comparable to other cells of the animal type There is little or no unsaponifiable matter, like phytosterol or other higher alcohols, such as are found in large amounts in some other micro-organisms, notably in the tubercle bacillus We may regard the gonococcus as a cell the content of which is soluble in and homogeneous with the surface membrane or limiting layer, even though the latter may preponderate in fatty constituents, which may, in turn, be soluble in and miscible with external agents, such as fats, soaps and fat solvents The surface membrane or layer is semipermeable, that is, permeable to water under certain conditions, and probably some crystalloids, but probably impermeable to most colloids, including its own Throughout my reports there has been made use of the comprehensive, or at all events, collective term "fats" for want of a better one This word is intended to include an order of chemical substances and compounds comprising those known as oils, containing fatty acid radicals in their structure, the acids and their salts, and those of more complex character, also, built about the fatty acids, called "lipoids," a term which, says Leathes, is a cloak for ignorance and an indefinable limbo into which any one can thrust anything of which he knows little or nothing, including what is often not a compound of a fatty acid at all These fats form a group separate, and almost without exception, distinct from those other classes of compounds, the carbohydrates and proteins, all of which collectively make up the living plasma The fats peculiar to the gonococcus have been, in part, described earlier

The protoplasm of the interior of the cell probably consists of a colloidal aggregate dispersed in a watery external or continuous phase, while the behavior of the limiting layer strongly suggests the reverse type in which water is the disperse phase in an external fat-protein phase This condition is comparable to the physical systems of water-oil mixtures In the interior of the cell is the oil-in-water emulsion, in the limiting layer the water-in-oil emulsion A nice illustration is offered by Clowes, in which the former state is like a group of islands surrounded by water, and the latter like a cluster of lakes surrounded by land In the first the permeability to water is free, in the second it is conditioned The conditions which regulate the permeability are for the most part due to the influence of electrolytes, to surface tension changes, and to what Loeb calls the driving force of osmotic pressure On these depend the life or death of the cell

A suspension of gonococci in water constitutes a suspension colloid (suspensoid) and the cocci are anions, that is, they carry an electronegative charge From such a dispersed state or phase the cocci may be flocculated (agglutinated) and undergo electrical change by cations, the flocculating power of which increases directly with the valence, i e , hydrogen, calcium and aluminum The agglutinating property of so-called immune serum is exceedingly variable and unreliable It is equaled and even surpassed by various normal serums Gonococci suspended in solutions of various electrolytes behave in manner comparable to cells of animal tissues to electrolytes The electrolytes functionate in the two divisions as made by Osterhaut Anions, such as hydrogen dioxid, sodium hydroxid and potassium hydroxid, increase the permeability of the cell Sodium chlorid acts as an anion, since the chlorin ion is more readily adsorbed than the sodium ion These anions, let us observe, promote the formation of emulsions of oil in water, such as we conceive to exist in the interior of the gonococcus cell, and their action on the cell is destructive On the other hand, cations, such as calcium, decrease the permeability of the cell, tend to promote the formation of water-in-oil emulsions, such as we believe to exist in the surface film of the cell, and may be protective Gonococci, in the presence of solutions containing antagonistic electrolytes, such as sodium hydroxid, and sodium chlorid or sodium hydroxid and calcium chlorid, tend to become agglutinated and in a degree protected, or undergo autolysis and destruction in proportion to the concentration of calcium and hydroxid ions Isotonic mixtures, such as Locke-Ringer solution, particularly if containing a little protective colloid, such as gelatin or agar, exert no immediate change in permeability and tend to preserve the cocci I was so impressed with this fact years ago that I advocated such a mixture as a culture medium Anesthetics, such as alcohol, ether and chloroform, exert solvent power for fat in higher concentrations, in low concentrations they act like calcium ions, producing agglutinative, protective effects Gonoc grows well in the presence of small quantities of alcohol

---

[2] Warden C C Jour Infect Dis May 1915

In all fluids in which water in excess is available, that is, in which the surface tension is high in the external phase, the cocci undergo autolysis and disintegration, primarily by reason of the semipermeable membrane Rupture of the cell due to distention by water depends in part on the weakness of the outer envelope If once excess of water gains entrance to the cell, electrolytically dissociated salts of protein may be formed by hydrogen or hydroxid ions of water, or by acid or alkali, and there is induced further swelling of the cell, due to the affinity for water of the protein ion In addition, some of the volatile fats of the cell are soluble or miscible with water and create a state tending to promote disintegration It is probable that the proteolytic ferments of the cell do not participate in the destruction to any extent during the life of the coccus

If the membrane is permeable to a solute of the outer phase, yet impermeable to its own cell contents, the ultimate state will be as if the outer fluid were water alone, since the concentration of the diffusible solute is soon equal on both sides of the membrane, whereon water is absorbed freely Hence suspensions of gonococcus in physiologic salt and various weak solutions behave similarly to suspensions in water With reference to the influence of osmotic pressure and surface tension on the gonococcus, it is interesting to observe the behavior of the latter under varying conditions of these forces Within the leukocytes, as in smears from gonorrheal exudate, the osmotic pressure of the white cell exceeds that of the coccus, the latter loses water and its surface tension is higher than in the surrounding medium In the presence of cations in solution, and of all fluids in which the cocci assume and maintain an approximately spherical contour, the surface tension is greater than that of the external fluid at the interface between the two On the contrary, the high surface tension of pure water and weak salt solutions and the greater osmotic pressure within the cocci cause their lysis and disintegration

On suitable culture mediums, and undoubtedly in the fluids of the body, the surface tension and osmotic pressure of the coccal cells are low, but about equal to those of the environment Through slight variation in the surface tension and osmotic pressures of the culture medium it is possible to study the reaction of the cocci through nice gradations from one extreme, at which all cocci autolyze and no growth occurs, through stages wherein colonies attain a certain size before all individuals composing them undergo lysis, giving the appearance of having "exploded," to the other extreme of optimum development

It is important to note the reaction of the gonococci to fats Neutral fats exert a protective influence The fatty acids in high concentration cause flocculation similarly to that produced by other acids and hydrogen ions In low concentrations, as 1 to 10,000, the agglutinative power is in abeyance and the surface tension at the interface between coccus membrane and water is lowered In addition there appears to be an adsorption of the acid by the coccus, together with solution of the former in the cell surface, or, in other words, a combination is formed whereby the permeability of the membrane is increased and the cell subsequently destroyed by imbibition of water The same applies to the salts and esters of the fatty acids in varying degrees The sodium and potassium salts of oleic acid are fatal to gonococcus through lysis in dilutions of 1 to 5,000, and the same effect is produced by salts of linoleic acid in concentration of 1 to 7,500 In this connection it is noted also that the fatty acids and alkali salts of the fatty acids composing the gonococcus exert even a greater effect, which may be taken to indicate a higher degree of solubility in the surface film

In general it may be said that the observations of Bancroft on the effects of the soaps on oil and water mixtures apply to the gonococcus Sodium soaps raise the surface tension of the oil, lower that of the water and tend to produce emulsion of oil in water Applied to the gonococcus, whose surface area we regard to be in the form of an emulsion of water in oil, sodium soaps tend to reverse the type, thus increasing the permeability of the membrane Calcium soaps, on the other hand, tend to produce emulsions of water in oil comparable to that existing at the surface of the gonococcus, and are thereby protective in their action The reversibility of colloidal states is a very important factor in the life of all cells

A suspension of gonococcus in serum or plasma, in vitro or in the body fluids in disease, constitutes the disperse phase of a suspensoid within another suspensoid (colloid) Each colloid may, and under proper conditions does, react on the other, leading to certain changes in the physical state of both Some of the changes are in a measure "specific" for the gonococcus, others may be produced as well by inert substances, such as starch, agar, kaolin and charcoal Let us examine a little closer the relation of the gonococcus to serum and body fluids The bodies of the cocci are in contact with a fluid of complex nature The surfaces of the cocci have become the disperse phase in a water suspensoid containing isosmotic values about equal to that of sodium and calcium salts, protein in a highly disperse state, sugar in solution, fats, fatty acids and soaps Laboratory observations indicate that the influences which operate on the gonococcus in water and various salt solutions also obtain with suspensions in serum Increase in water content of the external phase (serum) and corresponding decrease in concentration of salts and other matter produce effects approaching those caused by water, whereas increase in ionic fat or soap content exerts influences comparable to what are felt on addition of these substances to water

Through the phenomenon of adsorption the gonococcus membrane may in such colloidal solutions become more impermeable to water, leading to the checking of autolysis in laboratory experiment and tending to prolong or insure the life of the coccus in the body fluids On the other hand, the fact that there appears to be only very slight diminution of lysis of gonococcus in suspension in normal serum leads one to conclude that the adsorbed substances, partly of a fatty nature, may not materially decrease the permeability of the surface membrane or protect the cocci Theoretically the adsorbed fats, being more or less readily soluble in the gonococcus membrane, would tend to increase the permeability, and show that the fats may serve, at any rate in part, as a protection to the body In this connection it is not without interest to bear in mind the well-known clinical effects of fat solvents, such as alcohol, on the course of gonorrhea and other infectious diseases, and the laboratory effects, as shown in the disappearance of complement fixation reactions

The gonococcus is able to survive and propagate in a nutrient colloidal medium in which the balance of surface tension, osmotic pressure, density and other physical conditions in both is properly maintained. The balance is a nice one and slight variations in the physical state of the medium may destroy this balance and kill the organisms. Experiment indicates that on suspension of gonococci in fresh normal serum the germ bodies adsorb from the serum certain substances in part of a fatty nature, but that these fatty substances are of a different character from the fats of the cocci. The serum which has been subjected to the suspension of cocci in it becomes toxic, and kills the animal from which it was drawn, the homologous animal, in anaphylaxis. There is every reason to infer that a like though less severe phenomenon may occur within the body during the course of gonorrhea.

The gonococcus undergoes lysis to a greater or less extent in serum in laboratory experiments, and unquestionably the same is true at certain stages in the course of the infection within the body fluids. The serum therefore gains, besides protein and other substances not necessarily toxic, fats from the cocci. The protein constituents of the gonococcus appear to exert a negligible so-called antigenic effect on the body. The fats, on the other hand, produce considerable influence, though probably of a different kind. I have shown previously that the gonococcus fats serve as antigen in the complement-fixation. It is inferred that this phenomenon is due to the influence of these fats on the body fluids. It is apparent that this influence is not only brief, but is also not continuous, or rather that the gonococci undergo periods or waves of increased lysis and that these periods are synchronous with periods of positive complement fixation and with clinical signs of increased activity of the cocci, as shown by increased discharge and the numbers of them in the smears. Observations lead me to infer that an interrelationship exists between aggravated first-stage symptoms, lysis and excess of gonococcus fats in the body, and positive complement fixation on the one hand, and the following amelioration of symptoms, negative complement fixation and disappearance of the cocci and their fats on the other.

That the presence of excess of gonococcus fats in the body fluids is in relation to clinical improvement and even destruction of all cocci present may be explained by the fact that the substances that easily obtain entrance into the cell are in part, aside from water, just those that are soluble in fats or miscible with them. The fats of the gonococcus themselves are naturally most soluble and miscible of all, and if the surrounding fluids or serum contain sufficient of them, or excess over the ordinary fats of the serum, it becomes possible for the permeability of the cell membrane to be increased and destruction of the cell by water or other agents to ensue. In this connection it should not be forgotten that the solubility referred to may be only a more or less relative term to designate a surface tension and adsorption effect leading to modifications in the colloidal state of the membranes.

I stated in a previous paper before this section that excellent clinical results had followed in my hands the administration of the gonococcus fats in an oil menstruum. It is believed the foregoing conclusions may afford a working hypothesis for the fact. As control on the action of various fats following inoculation I have found that apparently no therapeutic effect is exerted by such neutral fats as olive, cottonseed, cocoanut, cod liver and linseed oils, or by the administration of such unsaturated fatty acids as oleic and linoleic in doses of 0.1 gm dissolved in oil. One fact learned from these experiments controlled by similar injections into laboratory animals is that parenteral injection of oils and fatty acids result in a partial local conversion of the free acids into the corresponding sodium salts.

Complement Fixation. The antigen composed of the gonococcus fats dissolved in alcohol has now been tested in over 1,900 cases. The work has been delayed partly by the difficulty of making sufficient of the antigen, the process requiring immense quantities of culture material, and partly because I was not satisfied with it. As was said a year ago, the question whether the fats as employed might not contain traces of protein did not then concern us, but later the question demanded an answer. Accordingly the presence of a protein rest was eliminated by converting the fats into the sodium salts of the fatty acids and purifying them repeatedly from alcohol. These salts, dissolved in alcohol, were found to possess much better antigenic power than the original. This antigen therefore has been used as control in our work and has substantiated the conclusions we formed a year ago. The expense and labor incident to the preparation of the antigen was the next difficulty to be overcome. This was done in the following manner. A study of the gonococcus fats showed them to possess certain physicochemical characters, acid values, molecular weights, melting and solidifying points, iodin values, etc., and indicated their relative proportions in combination. From these data it was possible to combine fats with identical values in the proper proportions. After some practice with tests alongside the control antigen this synthetic or artificial antigen was found to check perfectly and has since been employed in several hundred tests. As with the control, it was found also that alcoholic solution of the sodium salts of the fats composing the artificial antigen gave better results. A review of the cases tested with these antigens will form the material of a paper by Dr. J. B. Kelly and myself.

The foregoing facts lead to the question of the treatment of gonorrhea by the fats. Since my last paper no systematic work has been done, owing to the difficulties already mentioned and the necessity for centralizing effort on the study outlined. From our past experience and from the theoretical considerations arrived at I am convinced that the method of treatment warrants a fair and extended trial. The plan contemplates treatment with the gonococcus fats so far as is practicable and with the artificial combination in particular, since the latter affords less chance for variation in product and more accurate combination by weight. There is also indicated treatment with the salts of the artificial fats, preferably intravenously, as experiment has shown that in therapeutic doses so administered these salts, easily emulsified in salt solution or water, are harmless to animals.

With regard to theoretical and practical considerations of the phenomena concerned in the response of the body to gonococcus infection, in complement fixation and in therapeutics, I am convinced that hard and fast ideas of the so-called antigen-antibody combinations, amboceptors, etc., should be modified, or perhaps better, abandoned altogether. The problems are bound up with those physicochemical phenomena of surface tension, osmotic pressures, permeability and grows well in the presence of small quantities of alcohol

In all fluids in which water in excess is available, that is, in which the surface tension is high in the external phase, the cocci undergo autolysis and disintegration, primarily by reason of the semipermeable membrane Rupture of the cell due to distention by water depends in part on the weakness of the outer envelope If once excess of water gains entrance to the cell, electrolytically dissociated salts of protein may be formed by hydrogen or hydroxid ions of water, or by acid or alkali, and there is induced further swelling of the cell, due to the affinity for water of the protein ion In addition, some of the volatile fats of the cell are soluble or miscible with water and create a state tending to promote disintegration It is probable that the proteolytic ferments of the cell do not participate in the destruction to any extent during the life of the coccus

If the membrane is permeable to a solute of the outer phase, yet impermeable to its own cell contents, the ultimate state will be as if the outer fluid were water alone, since the concentration of the diffusible solute is soon equal on both sides of the membrane, whereon water is absorbed freely Hence suspensions of gonococcus in physiologic salt and various weak solutions behave similarly to suspensions in water With reference to the influence of osmotic pressure and surface tension on the gonococcus, it is interesting to observe the behavior of the latter under varying conditions of these forces Within the leukocytes, as in smears from gonorrheal exudate, the osmotic pressure of the white cell exceeds that of the coccus, the latter loses water and its surface tension is higher than in the surrounding medium In the presence of cations in solution, and of all fluids in which the cocci assume and maintain an approximately spherical contour, the surface tension is greater than that of the external fluid at the interface between the two On the contrary, the high surface tension of pure water and weak salt solutions and the greater osmotic pressure within the cocci cause their lysis and disintegration

On suitable culture mediums, and undoubtedly in the fluids of the body, the surface tension and osmotic pressure of the coccal cells are low, but about equal to those of the environment Through slight variation in the surface tension and osmotic pressures of the culture medium it is possible to study the reaction of the cocci through nice gradations from one extreme, at which all cocci autolyze and no growth occurs, through stages wherein colonies attain a certain size before all individuals composing them undergo lysis, giving the appearance of having "exploded," to the other extreme of optimum development

It is important to note the reaction of the gonococci to fats Neutral fats exert a protective influence The fatty acids in high concentration cause flocculation similarly to that produced by other acids and hydrogen ions In low concentrations, as 1 to 10,000, the agglutinative power is in abeyance and the surface tension at the interface between coccus membrane and water is lowered In addition there appears to be an adsorption of the acid by the coccus, together with solution of the former in the cell surface, or, in other words, a combination is formed whereby the permeability of the membrane is increased and the cell subsequently destroyed by imbibition of water The same applies to the salts and esters of the fatty acids in varying degrees The sodium and potassium salts of oleic acid are fatal to gonococcus through lysis in dilutions of 1 to 5,000, and the same effect is produced by salts of linoleic acid in concentration of 1 to 7,500 In this connection it is noted also that the fatty acids and alkali salts of the fatty acids composing the gonococcus exert even a greater effect, which may be taken to indicate a higher degree of solubility in the surface film

The gonococcus is able to survive and propagate in a nutrient colloidal medium in which the balance of surface tension, osmotic pressure, density and other physical conditions in both is properly maintained The balance is a nice one and slight variations in the physical state of the medium may destroy this balance and kill the organisms Experiment indicates that on suspension of gonococci in fresh normal serum the germ bodies adsorb from the serum certain substances in part of a fatty nature, but that these fatty substances are of a different character from the fats of the cocci The serum which has been subjected to the suspension of cocci in it becomes toxic, and kills the animal from which it was drawn, the homologous animal, in anaphylaxis There is every reason to infer that a like though less severe phenomenon may occur within the body during the course of gonorrhea

The gonococcus undergoes lysis to a greater or less extent in serum in laboratory experiments, and unquestionably the same is true at certain stages in the course of the infection within the body fluids The serum therefore gains, besides protein and other substances not necessarily toxic, fats from the cocci The protein constituents of the gonococcus appear to exert a negligible so-called antigenic effect on the body The fats, on the other hand, produce considerable influence, though probably of a different kind I have shown previously that the gonococcus fats serve as antigen in the complement-fixation It is inferred that this phenomenon is due to the influence of these fats on the body fluids It is apparent that this influence is not only brief, but is also not continuous, or rather that the gonococci undergo periods or waves of increased lysis and that these periods are synchronous with periods of positive complement fixation and with clinical signs of increased activity of the cocci, as shown by increased discharge and the numbers of them in the smears Observations lead me to infer that an interrelationship exists between aggravated first-stage symptoms, lysis and excess of gonococcus fats in the body, and positive complement fixation on the one hand, and the following amelioration of symptoms, negative complement fixation and disappearance of the cocci and their fats on the other

That the presence of excess of gonococcus fats in the body fluids is in relation to clinical improvement and even destruction of all cocci present may be explained by the fact that the substances that easily obtain entrance into the cell are in part, aside from water, just those that are soluble in fats or miscible with them The fats of the gonococcus themselves are naturally most soluble and miscible of all, and if the surrounding fluids or serum contain sufficient of them, or excess over the ordinary fats of the serum, it becomes possible for the permeability of the cell membrane to be increased and destruction of the cell by water or other agents to ensue In this connection it should not be forgotten that the solubility referred to may be only a more or less relative term to designate a surface tension and adsorption effect leading to modifications in the colloidal state of the membranes

I stated in a previous paper before this section that excellent clinical results had followed in my hands the administration of the gonococcus fats in an oil menstruum It is believed the foregoing conclusions may afford a working hypothesis for the fact As control on the action of various fats following inoculation I have found that apparently no therapeutic effect is exerted by such neutral fats as olive, cottonseed, cocoanut, cod liver and linseed oils, or by the administration of such unsaturated fatty acids as oleic and linoleic in doses of 0 1 gm dissolved in oil One fact learned from these experiments controlled by similar injections into laboratory animals is that parenteral injection of oils and fatty acids result in a partial local conversion of the free acids into the corresponding sodium salts

Complement Fixation The antigen composed of the gonococcus fats dissolved in alcohol has now been tested in over 1,900 cases The work has been delayed partly by the difficulty of making sufficient of the antigen, the process requiring immense quantities of culture material, and partly because I was not satisfied with it As was said a year ago, the question whether the fats as employed might not contain traces of protein did not then concern us, but later the question demanded an answer Accordingly the presence of a protein rest was eliminated by converting the fats into the sodium salts of the fatty acids and purifying them repeatedly from alcohol These salts, dissolved in alcohol, were found to possess much better antigenic power than the original This antigen therefore has been used as control in our work and has substantiated the conclusions we formed a year ago The expense and labor incident to the preparation of the antigen was the next difficulty to be overcome This was done in the following manner A study of the gonococcus fats showed them to possess certain physicochemical characters, acid values, molecular weights, melting and solidifying points, iodin values, etc, and indicated their relative proportions in combination From these data it was possible to combine fats with identical values in the proper proportions After some practice with tests alongside the control antigen this synthetic or artificial antigen was found to check perfectly and has since been employed in several hundred tests As with the control, it was found also that alcoholic solution of the sodium salts of the fats composing the artificial antigen gave better results A review of the cases tested with these antigens will form the material of a paper by Dr J B Kelly and myself

The foregoing facts lead to the question of the treatment of gonorrhea by the fats Since my last paper no systematic work has been done, owing to the difficulties already mentioned and the necessity for centralizing effort on the study outlined From our past experience and from the theoretical considerations arrived at I am convinced that the method of treatment warrants a fair and extended trial The plan contemplates treatment with the gonococcus fats so far as is practicable and with the artificial combination in particular, since the latter affords less chance for variation in product and more accurate combination by weight There is also indicated treatment with the salts of the artificial fats, preferably intravenously, as experiment has shown that in therapeutic doses so administered these salts, easily emulsified in salt solution or water, are harmless to animals

With regard to theoretical and practical considerations of the phenomena concerned in the response of the body to gonococcus infection, in complement fixation and in therapeutics, I am convinced that hard and fast ideas of the so-called antigen-antibody combinations, amboceptors, etc, should be modified, or perhaps better, abandoned altogether The problems are bound up with those physicochemical phenomena of surface tension, osmotic pressures, permeability and solubility and the interaction of colloidal solutions in general, including anaphylaxis In respect to anaphylaxis it should be borne in mind that recent experiments indicate there is probably no difference between specific anaphylaxis, namely, that produced by the same substance as the inducing substance, and the ordinary nonspecific anaphylaxis induced by almost any substance leading to change in the physical state of the body fluids In practice I have frequently observed in patients the symptoms of anaphylaxis as evidenced by chill, fever and urticaria following inoculations of gonococcus substance in various forms subcutaneously and intravenously These symptoms have been regarded as manifestations of nonspecific anaphylaxis, since they were produced by control intravenous injections of distilled water and the shock itself unattended by appreciable modification of the infection This ordinary shock is identical with that induced by water, agar or kaolin injections in laboratory animals, and that frequently recorded in recent years following intravenous injections of various serums and certain other therapeutic agents The contention of Gay and others that beneficial effect in such cases is due to results of this shock of ordinary type seems to lack sufficient support

The physicochemical entity of the gonococcus reacts with the serum complex in a definite manner, inducing certain changes in each, which operate, on the one hand, to viability of the germs, on the other, to their extinction, depending on a shift of balance between forces in which the fats undoubtedly play an important role Into this view is admitted the specificity of antigen, but I am inclined to dispute the antigen-antibody idea as ordinarily understood The solution of the problem is found in less vague processes

It is perhaps not inadmissible at this time to state that the ideas expressed here with reference to the gonococus may be found serviceable in work on other bacteria, particularly on other members of the *Coccaceae* group, but also on organisms rich in fats, which produce such changes in the serum in disease as to lead to complement fixation with fat antigens Only recently we have produced in the laboratory an artificial syphilitic antigen for use in the Wassermann reaction This antigen has been tested and made to agree with two standard antigens, consisting of alcoholic extracts of human heart, which had been shown to agree with each other From the facts noted there is drawn the tentative inference that the fixation of complement in gonorrhea and syphilis is due to the influence of fats alone

ABSTRACT OF DISCUSSION

Dr Louis E Schmidt, Chicago Warden reiterates "that all forms of serums and vaccines hitherto employed against gonorrhea were without definite dependable value" I need not enumerate the various agents included in this category—as I include them all—and wish to emphasize that any and all have not come up to expectations in clinical work Whether or not Warden's exhaustive and painstaking work is sufficient to explain the reasons thereof yet, I believe it points out the error of our ways, when it comes to the promiscuous use of serums and vaccines in gonorrheal diseases He must give still more evidence in regard to the "fat" of the gonococcus before it can be regarded as a specific in treatment As to the antigen, I must admit that it has shown itself superior to other antigens and for this reason the "fat agents" may also be proportionately better than the serums and vaccines used previously Certainly, the theoretical and practical bearing of the problems of chemicophysics on immunity deserves the most careful consideration There can be no question that the finding of the specific antibody in the blood gave rise to the theoretical basis of vaccine treatment For this reason all the serums and vaccines whenever used have been to some extent controlled with gonorrheal complement tests To some extent symptoms and signs are in accord with this view It was noticed that following injections of certain agents, a rise in temperature was not uncommon Many cutaneous reactions occurred, local reactions became more pronounced and then lessened in severity Yet with all this evidence there has always been a belief that many satisfactory results have not been based on the action of specific antibodies and much experimental and clinical work has been done to show that certain albumins have given favorable results and in most instances that following the injection thereof the rise in temperature has been noticed and that the changes thus produced were the cause of the improvement In my opinion there is no question that vaccines and serums of all types that have been used in gonorrhea and its complications have not come up to our expectations

Dr Edward L Keyes, Jr, New York I have been guilty of expressing in print great confidence in various kinds of vaccines and serums At the present moment I do not feel any confidence in vaccines or serums I have arrived at the same conclusion as Dr Warden and Dr Schmidt

Dr Benjamin Gruskin, Chicago I have used Warden's antigen in connection with other gonorrheal antigens In fifteen cases, nine that were negative or faintly positive with other antigens showed a sharper reaction with Dr Warden's antigen Other cases that I would have thought negative I have been able to report as positive, and the clinical history, as the doctors reported to me afterward, proved that the patients had had gonorrhea a year or so before I find it the best antigen I have ever used

Dr Theodore Baker, Pittsburgh I have had some apparent success with vaccines, and, using the same technic, have had failures On reviewing the histories of the cases that had been a success and those that had been failures I found one significant fact In those that had been a success the vaccines produced a marked local and a marked general reaction In those that had been failures there was the very slightest reaction with large doses of the vaccine, or no reaction at all I found also that by keeping the vaccines on ice they lost their potency I think that specific vaccines are still worth trying We should be cautious in using other nonspecific proteins and giving up the general use of specific vaccines, as has recently been attempted

Dr John R Brown, Tacoma Wash We have tried autogenous vaccines, stock vaccines, simple vaccines and mixed vaccines and I am satisfied that they have not made good Occasionally I have seen a case where they seemed to do some good, and those are the cases, as mentioned by Dr Baker, that gave an intense reaction Therefore, if we are going to expect any good at all we must use larger doses than those advised, or at least large enough to cause not only a local but a constitutional reaction I also think it does not make much difference what organism you use, just so you get the reaction, because perhaps it is true, as pointed out recently, that it is a protein poison that causes leukocytosis and that the only virtue vaccines possess is that of stimulation to leukocytosis I was very much interested in the changes in morphology in the gonococcus when treated with various solutions We have noticed the same occurrence in our own work For two years or more we have been experimenting in a comparatively large number of cases with heated sounds treatment of gonorrhea In the hands of a man who will make a diagnosis and locate the disease this treatment is of immense value, especially in the acute cases and even in the chronic cases Many cases of chronic prostatitis and seminal vesiculitis, when treated through the rectum through a suitable rubber bag heated by water running through it at 135 degrees, are favorably influenced It was after these treatments that we noted the morphologic changes Dr Warden mentioned

Dr Edwin Beer, New York The remark made by the last speaker and the previous speaker should be challenged that if there is a reaction possibly we get good results With a very varied experience not only in genito urinary but in general surgery treating staphylococcus, streptococcus, gonococcus, tuberculous and other infections, I have come to the conclusion which Dr Schmidt expressed that there is nothing absolutely reliable in the vaccine treatment During the last year and a half we have been following a series of cases, mostly genito-urinary cases due to tuberculosis, with the Rosenbach tuberculin, which has been very much vaunted abroad and which is a vaccine treatment, and the general conclusion which we have reached in treating fistula after nephrectomies and due to tuberculous epididymitis is that the Rosenbach tuberculin is of practically no value The second vaccine with which we worked was the Nicolle vaccine for gonococcus infections, and although once in a while we saw remarkable results, the totality of results were no better than from any other treatment So in general I would say that Nicolle vaccine has not been satisfactory When it comes to treating cases with colon vaccine I think everybody is reminded that there may be something in the treatment, although experience, on the whole, is opposed to the view that it is specific For instance, take pyelonephritis due to the colon bacillus All of us have treated protracted cases with high temperature with vaccine, and every once in a while we see a remarkable result but when that result is exceptional, when it does not follow with regularity in colon pyelonephritis cases, both in the acute and chronic stages, one cannot help but doubt that the success in one case was accidental rather than the result of the vaccine treatment. So that I would be inclined to go on record in stating that up to date, the results from vaccines have been very unsatisfactory I am now beginning to treat a series of cases with sensitized vaccines following Beredka but owing to the difficulty in procuring autogenous sensitized vaccines, we are compelled to make use of the stock preparations prepared by Mulford

Dr. W Jones Wallace Oklahoma City I have used vaccines a good deal, and to my mind they should be used in selected cases or in complications In acute cases I never use them, but when it comes to the chronic cases or when there is an epididymitis or an arthritis or some other complication, vaccines can be used with advantage The great trouble is that we do not use vaccine in large enough doses I often use a stock vaccine but I do not follow the directions given in the circulars I repeat the dose each succeeding day until I get some reaction

Dr Martin Krotoszyner, San Francisco The efficacy of vaccine therapy, which is undoubtedly an important addition to our armamentarium against gonorrhea, is jeopardized by its frequent uncritical application in the past Like other therapeutic measures, vaccine therapy was in the beginning of its use praised to the skies, and is of late because it has not yielded the expected results, meeting with a great deal of adverse and unmerited criticism, which more justly should be applied to the unscientific use of this therapeutic agent The indiscriminate use of stock vaccines for all forms and stages of gonorrhea should be discouraged It is well known that the various vaccine strains of the gonococcus differ widely in endotoxins and that it is, therefore, impossible to bring into one vaccine all strains required for the formation of antibodies Thus divergent results in vaccine-reactions and therapeutic efficacy in apparently identical clinical lesions find their explanation The solution of the problem in getting more uniform results is dependent, *in my opinion* on the application of carefully prepared autogenous vaccines Vaccine therapy, under these conditions, should always be conducted clinically, and good results may be expected by carefully conducted vaccine therapy at hospitals, equipped with scientific laboratory facilities for these purposes

Dr E G Crabtree, Boston I cannot leave unemphasized one point that Dr Warden has brought out which I think is probably the key to vaccine treatment We have been accustomed to give vaccines without carefully studying bacterial life in the way that Dr Warden has studied the gonococcus

It is undoubtedly true that most bacteria in their acute stage produce antibodies which persist for varying lengths of time, the exact duration of which we do not know, and in many cases we are not concerned with it. Bacteria which are quiescent or which occupy some remote part of the body apparently do not produce antibodies, but diagnoses are made because of that antibody production which occurred during the acute infection It has already been established by clinical use of vaccines that recurrences are often prevented, and in the great majority of cases symptoms relieved That is particularly borne out in the vaccine treatment of colon pyelonephritis You can feel sure that recurrence will not take place As a curative agent, however, the colon vaccine has proved a failure We have nothing to indicate that the products elaborated in the blood reach the urine as such, and unless the process is acute our vaccine treatment is probably not effective Undoubtedly a more careful study of the cell content of the various bacteria and a more careful study of blood manifestations, particularly in the acute stage of infection, will lead us to a better working basis in vaccine therapy

Dr Victor G Vecki, San Francisco While I have more than one patient who swears by me because I cured him with autogenous and other vaccines, I must say that I have abandoned this treatment I have come back to the conclusion I cited several years ago that the results obtained in vaccine and serum treatment are probably due to the circumstance that the urethra having previously been overtreated is under the vaccine treatment given some rest at the expense of the patient's 'hide"

Dr Louis E Schmidt Chicago I had reference chiefly to gonorrhea and its treatment with vaccines and serums made from the gonococcus I do not doubt that there are many cases that have been improved and possibly cured by the various vaccines and serums and combinations that have been used The question is whether or not it is by specific antibodies There has been an enormous amount of work done in connection with the injection of so called harmless remedies or agents for instance, milk. Milk is being injected in 5 or 10 c c doses into the glutei and exactly the same reactions occur and the same astounding results have been shown Now, how is the result obtained? Sometimes there is a high rise of temperature, and then possibly by-products have been produced by injecting these agents Whether or not they are specific, that is the question For that reason, I am still in doubt as to whether it is necessary, or whether the agents that have been produced in the gonococcus are absolutely essential For that reason I am inclined to believe that some of the artificial products that Dr Warden has taken up will probably prove as successful, if not more so, than those that have been in use up to the present time

Dr Carl C Warden, Ann Arbor, Mich One further word about these fat antigens and how they work If we were to regard the gonococcus alone from which a fatty antigen has been obtained for complement fixation, it would require considerable temerity to assign all antigenic properties to fats alone but only lately we have been able to do the same thing with the Wassermann, that is, we have made an artificial fat antigen that concurs with two other antigens which have been standardized and which agree among themselves Many substances of a fatty nature put into a solution will immediately lower the surface tension of that fluid a great deal, and any substance that lowers tension is bound to appear at the interface between two systems and these fats are found at the interfaces of the substances composing the solution In consequence, they must act in some such way in complement fixation in order to allow or prevent the hemolysis The ideas as to antibodies will gradually undergo a change and we may come to view the antibody not as a definite substance, but rather as a condition or a state of the body fluids Recent experiments have shown that normal serum removed from the body becomes toxic under certain conditions Its toxicity will wear off in a short time, and it will undergo fluctuations of toxicity and nontoxicity During the toxic stage the complement disappears Whether that is a *definite substance* we are beginning to doubt It looks as though the complement itself might be a highly dispersed state or condition in the serum itself or in the body fluids We know that in living tissues in health fat is not commonly seen in the cells, but once a foreign substance like a fat solvent is applied, some of these cells will show fat globules These cells do not contain any more fat than they did before, but the colloidal state has undergone such a change that the fat globules have been allowed to coalesce So I think that in some of these forms of disease caused by the *Coccaceae* we will come to believe that the antibody itself is a very slight factor, that more depends on the state of the body fluids or the state of the serum, and that certain conditions may arise where the germs can exist no longer, and other conditions may exist where the germs may be able to multiply and grow I believe the time is coming soon when we shall be able to cure an attack of gonorrhea, but it will have to be done only by careful study of the condition or state of the body fluids of the patient at the time I believe there is a relationship between this complement fixation and the state of the blood whereby the life of the gonococcus is extremely precarious, and that we shall be able by some means, possibly by these fat remedies which I have suggested, to shift the balance of the surface tension just sufficient to cause the death of the coccus forms that are there It will not produce an immunity, it will not be fool proof under any circumstances, but it will probably be sufficient It will not be able to dispose of all the gonococci that can exist in a saprophytic condition on the mucous membrane, but it will kill the gonococci inside the cells or tissues As Dr Crabtree says in relation to the colon bacillus, the vaccine will relieve the inflammation in colon bacillus infections, but it will not get rid of the colon bacillus

SPASMODIC ASTHMA

REPORT OF CASES ILLUSTRATING ITS ANAPHYLACTIC NATURE AND THE DIFFICULTIES IN THE WAY OF SUCCESSFUL TREATMENT

ROBERT HALL BABCOCK, MD, LLD
CHICAGO

In a previous paper,[1] special consideration was given to the nature and treatment of bronchial asthma Since then a number of cases have been treated in accordance with the views therein set down, and a good many inquiries have been received relative to the subject, therefore I have decided to make the following reports in the hope of assisting other workers in the solution of the problems confronting them

With increased experience, the conviction expressed in the paper referred to has been strengthened, and in particular it has been demonstrated that no pains must be spared in searching for and removing every diseased process which may serve as a focus for protein absorption Furthermore, in many cases more than one such focus exists, and it would seem as if sensitization to protein from one source renders the individual peculiarly liable to sensitization to other proteins and to proteins absorbed from different situations within his body This is especially well shown in persons suffering from so-called hay-fever or hay-asthma And here it may be stated that, with one exception, the cases herein reported are instances of typical spasmodic asthma independent of the summer and autumnal disease generally caused by sensitization to some plant or animal protein The foreign protein at work was furnished within their own bodies, and not from sources situated without their own economy

As will be seen, the focus or foci may generally be found in the nares or accessory parts, as ethmoid or sinuses, but diseased tonsils and suppurative processes about the gums or tooth roots may prove a very fruitful source of mischief In cases of long standing with frequent repetition of asthmatic seizures, chronic bronchitis often supervenes and then may furnish the bacterial protein after all other foci have been removed by operation That a focus of infection outside the respiratory tract may be responsible for the asthma is quite possible, as was shown by the case mentioned in my previous article of freedom from asthma so long as the infected gallbladder was permitted to drain freely, and of return of the paroxysmal dyspnea when drainage ceased

It should be stated, moreover, that further acquaintance with this class of sufferers suggests that some additional factor as yet unsolved may underlie or be associated with their sensitization to a foreign protein That spasmodic asthma is not a nervous affection, as assumed by early writers, and, indeed, is not due to the effect of the poison on the central nervous system is proved by the occurrence of the phenomena even after all connection between the bronchioles and spinal cord was destroyed in the guinea-pigs experimented on by Auer and Lewis Nevertheless, one cannot see much of these sufferers without getting the impression that some sort of connection does exist between the asthmatic condition and the nervous make-up of the individual Whether there is some peculiarity or susceptibility of bronchial muscles predisposing certain persons to this particular manifestation of anaphylaxis, or whether the instability of the nervous system seen in them is a result or effect of the asthma is difficult to determine Certainly the question is suggested, Why do some persons manifest asthma when others with an identical focus of infection and the same organisms in cultures from the material of the foci do not show asthma? Dogs and guinea-pigs react differently to the same protein, but these animals are of different species What, then, is it in human animals of the same species which causes a different reaction to apparently the same protein? It would seem as if some additional and as yet unknown factor still has to be discovered

Case 1—Mrs N H B, aged 55, was seen, Sept 1, 1914 because of severe attacks of spasmodic dyspnea from which she had suffered for the better part of a year The family history was negative, and the personal facts, briefly stated, were tonsillitis and appendicitis ten years before, and in September, 1913, an acute coryza which at length resulted in bronchitis for which she spent the winter in the South Returning North in the early spring she became so much worse en route as to necessitate stopping in Atlanta, Ga, for medical care When the patient recovered from the illness, which, as seems likely, was a bronchopneumonia, her dyspnea took on the character of typical spasmodic asthma After spending the following summer in Colorado under competent medical care without benefit, she returned to her Chicago home and consulted me

It was learned that she had for months been having recurrences of spasmodic dyspnea quite regularly every four hours which yielded only imperfectly to subcutaneous injections of a solution of epinephrin, from 4 to 8 minims of a 1 1,000 solution She also thought she obtained slight relief from her difficult, harassing cough from 4-grain doses of potassium iodid three times daily Examination of the chest disclosed hyperresonance with characteristic prolongation of expiration and copious sibilant rhonchi In the left lower back however, was a small area in which slight dulness could be detected and medium sized mucous rales could be heard, signs thought to have resulted from the patient's acute illness in Atlanta The heart was negative in all respects, as were blood pressure, temperature, blood count and urine A competent rhinologist and laryngologist reported the nose and throat free from any abnormality responsible for the asthma Films were then made of the teeth and disclosed a small alveolar abscess for the cure of which one tooth was extracted, but without appreciable effect on the asthma A roentgenogram of the lungs revealed what appeared to be a small area of thickening in the posterior base of the left lung where it was thought a patch of bronchopneumonia had existed

---

[1] Babcock R H The Nature and Treatment of Bronchial Asthma, The Journal A M A, June 26, 1915, p 2115

During the two weeks required for this study of the case, asthmatic paroxysms were of daily and nightly occurrence, necessitating frequent resort to epinephrin. A vaccine was now prepared from the sputum, and consisted of *Micrococcus catarrhalis* and was administered carefully with appreciable lessening of the bronchitis, though slight influence over the asthma. A week later culture of the sputum yielded *M. catarrhalis* but in addition the pneumococcus, an anaerobic fusiform bacillus and *Streptococcus viridans*. A second vaccine was therefore prepared and carefully administered until toward the end of October. Some improvement was shown for a time, but a relapse occurring, a third vaccine was made, since now the culture from sputum yielded a preponderating number of the fusiform bacillus. In November, asthma was less frequent but cough was more troublesome with less stringy, more fluid mucus.

The course of the disease was henceforth most checkered with periods of improvement interspersed with others of aggravated dyspnea, more troublesome cough, and an increased number of wheezing and mucous rales, so that not only were repeated changes made in the vaccines, but also recourse was had to various expectorant remedies, including aspidospermin, which seemed to afford the greatest relief. In March, 1915, after a short period of encouraging improvement, the patient contracted a sharp rise of temperature with greatly aggravated cough and dyspnea, though not of the paroxysmal type previously observed. At this time, culture of the sputum showed typical pneumococcus and practical disappearance of the organisms previously obtained. Nevertheless with subsidence of temperature and disappearance of pneumococci the asthma recurred in full force. At length in the summer of 1915 the asthmatic condition mended appreciably, and we were all encouraged, only again to be disappointed by return of the asthma in full vigor by September. During all these months everything had been done that could be devised with no greater result than to rid the lungs of most of the bronchitis, save in the left lower back, where evidently some permanent change in lung structure had taken place.

At times when this patient's asthmatic symptoms were least apparent a frequent racking cough still persisted and caused considerable feeling of stuffiness, as she expressed it. Finally in October she decided to change physicians and I was dismissed. What afterward was done is known only through hearsay, but it is known that a number of new vaccines were prepared and administered without, however, entirely relieving the asthma. Finally completely discouraged, this poor sufferer ended it all by voluntary and tragic death.

CASE 2.—Mrs. D., aged 44, seen March 23, 1915, had suffered from bronchial asthma since the early fall preceding. She was found to have small but diseased tonsils, an alveolar abscess, chronic bronchitis and a pyosalpinx. The alveolar abscess was removed by extraction of the diseased teeth, and anaerobic and aerobic cultures of the pus on blood agar and ascitic bouillon showed *Streptococcus mucosus* and pneumococcus-like diplococcus. From this pus no vaccine was prepared as the evacuation of the abscess cavity was thought sufficient to remove protein absorption from that focus. As the patient had chronic bronchitis with sputum, a culture of this was next made after careful washing and it showed anaerobically and aerobically *Micrococcus catarrhalis*, *Diplococcus mucosus* and a very few influenza-like bacilli. Owing to the absence of fusiform bacilli no vaccine was prepared until toward the end of April when a few anaerobic fusiform bacilli were found in addition to *Micrococcus catarrhalis* and *Diplococcus mucosus*. In June another vaccine was prepared of the same organisms, except that the fusiform bacilli were more numerous. On regular cautious employment of this vaccine, together with a cough mixture containing lobelia, improvement proceeded gradually though not uninterruptedly, until by July she declared herself free from asthma.

In October following she contracted a coryza coincidently with menstruation, and soon thereafter experienced a recurrence of her old enemy in severe form. Completely discouraged she not long afterward left Chicago, and has been heard from but once since when severe asthma was reported. During her asthma-free interval, the tonsils were extirpated, but despite the advice to have the pyosalpinx removed, this was not done. How much influence could be attached to this focus of infection could not be determined, but it was considered a mistake to leave it unoperated, especially as it was uncertain whether the relapse in October was due to the coryza or to absorption from the pyosalpinx coincident with the appearance of the menses.

CASE 3.—Mrs. B., aged 29, examined Aug. 11, 1915, had suffered from asthma since the age of 6. She was found to have chronic ethmoiditis with polypi, badly infected tonsils and alveolar abscess with chronic bronchitis. Culture of the pus from the jaw showed no fusiform bacilli, but *Diplococcus mucosus*, *Streptococcus viridans*, staphylococcus and the diphtheroid bacillus. No vaccine was prepared because of the belief that the anaerobic fusiform bacillus is the organism having most influence over the asthma, and that without it vaccines would be inert. In addition to extraction of the diseased teeth, a tonsillectomy and removal of the nasal polyps, as much work was done on the ethmoid as was possible at the time. August 16 a vaccine was prepared from the tenacious slightly purulent sputum and contained a large number of the fusiform bacillus.

After completion of all the operative work, the patient returned home and continued the use of the autogenous vaccine until December, when another specimen of sputum showed on culture the fusiform bacillus as well as several other organisms. Treatment was continued along the same line during the succeeding winter but without as decided improvement as was hoped. At length, early in the past summer this patient reappeared in Chicago in consequence of exacerbation of her asthma, although it was not so distressing as a year previous. Examination disclosed retention of nasal secretion in consequence of a hypertrophied turbinate, and in addition considerable bronchitis. Proper treatment of the nose was at once instituted, and a vaccine was prepared from the sputum, the culture showing as before the anaerobic fusiform bacillus. At present writing, August 24, she is receiving this vaccine and is fairly comfortable, though not wholly free from some asthmatic stuffiness.

CASE 4.—Mrs. S., aged 32, sought advice Feb. 17, 1915, because of asthma. There was a history of appendicitis fifteen years before and a curettage two years ago, but no other definite illnesses. She was found to have chronic ethmoiditis with polypi, pyorrhea, diseased tooth roots and extensive bronchitis in both lungs. There was also a systolic murmur in both mitral and tricuspid areas. The nasal and mouth conditions required much operative work, and this being impossible for financial and other reasons, among the latter being daily asthmatic seizures, treatment dragged along for many months. Meanwhile attempts were made to lessen the bronchitis and cough by means of various expectorant and sedative remedies as well as by vaccines made from the sputum. This in June, 1915, contained *Micrococcus catarrhalis* and *Diplococcus mucosus*. July 25, 10 minims of this vaccine were followed by severe reaction, fever, increased cough and asthma. August 7, the patient reported the extraction of some of the teeth and was feeling somewhat better. August 30 the asthma was less and a slight gain in weight was recorded. September 8 more asthma was reported after the last injection but the lungs yielded no rales except in the lower right back. September 15 a second vaccine made from sputum contained *Micrococcus catarrhalis*, *Diplococcus mucosus*, staphylococcus and a few fusiform bacilli. From this date my records are wanting as the patient has not come at all regularly for the vaccine injection. She has submitted from time to time to palliative but not radical operations on the nose since her reduced physical state was such that the rhinologist dared not subject her to any severe operative procedure. She is, therefore, after eighteen months still suffering from her old enemy. It is considered unfortunate that this patient's circumstances have not permitted prolonged hospital treatment with a view to establishing sufficient resistance to enable her to bear whatever operations might be necessary to remove all foci of infection in the ethmoid and elsewhere.

CASE 5—Mr L, attorney, aged 41, examined July 19, 1915, had suffered from asthmatic attacks since May, 1914, the seizures being most frequent at night Family history was negative, but in personal anamnesis there were frequent attacks of grip, an appendicectomy a year before, and alcohol to excess some years earlier Careful physical examination disclosed no disease of the heart, kidneys and other viscera, but a few fine mucous rales in the lower back on both sides The turbinates were fairly large and the septum posteriorly was deflected to the left, but these conditions did not interfere with free drainage The tonsils were large, submerged and showed open crypts without retained secretions The gums and teeth appeared to be in good condition, but as the leukocytes numbered 13,200, roentgenograms of the teeth were made, which disclosed two abscesses at the roots of the right upper bicuspid and adjacent incisor These two teeth were extracted and the abscesses were cleaned out Ten days later cultures of the sputum were made and disclosed *Diplococcus mucosus,* an influenza-like bacillus, and the fusiform bacillus A vaccine was prepared and administered for a month, at which time the asthma had vanished, although cough and a few rales still persisted Thereupon, August 25 another culture of the sputum was made and a vaccine was prepared which now contained *Diplococcus mucosus,* 40 per cent, *Micrococcus catarrhalis,* 50 per cent, and a small number of the streptothrix and bacillus mucosus capsulatus This second vaccine caused prompt disappearance of all signs of bronchitis, and by the first of September the patient felt so well that he insisted on returning to his home to take part in a stormy political campaign Consent was accorded, provided he would take along the vaccine and have it administered, but as the sequel showed this was a mistake Either because of the reaction following a too large dose of the vaccine, or because of his strenuous duties, his asthma soon reappeared and necessitated recourse to epinephrin Nevertheless in a letter just received he states that with exception of the three attacks which occurred soon after his return to his home, he has experienced no paroxysms, but that after lying down in bed at night he sometimes notices a little wheezing On the whole, however, he considers himself well, but is not certain whether this is due to the treatment received in Chicago or whether, as assured by some of his medical friends, he would in time have grown out of the asthma at home In my opinion, formed from observation of asthma cases, he would still be suffering with unabated intensity, had he not got rid of his mouth and bronchial foci of infection This reflection leads to the conjecture that the wheezing still noticed by this patient may find its explanation in the fact of some persisting bronchitis which the vaccine did not wholly clear up

CASE 6—Miss L, aged 48, examined Oct 7, 1915, had suffered from nightly attacks of asthma for a year and a half, although her initial seizure occurred four years before, after what she called a cold She was found to have badly diseased tonsils and abscesses at the roots of three teeth There was no evidence of chronic bronchitis The tonsils were removed, the diseased teeth extracted, and a vaccine prepared from the pus of the alveolar abscess This vaccine contained a variety of organisms, and among these the fusiform bacillus She has been seen within the past few weeks, August, 1916, and declares she has had no asthma since recovering from the tonsillectomy She thinks the vaccine was not necessary, although it was employed for a few weeks

CASE 7—Mrs B L, aged 36, had suffered from asthma since early childhood, but had not developed secondary bronchitis She was first seen by me in 1900, at which time she was having hemoptysis believed to be due to left apex tuberculosis From this she recovered, but since then has suffered from her asthma frequently, especially in bad, foggy weather She had chronic ethmoiditis, a sinus infection and infected tonsils The nasal and sinus disease was treated from time to time, but not radically until last spring, at which time the tonsils also were removed She was entirely free from asthma until the onset of hay-fever toward the end of August, 1916 As it is, her dyspnea lacks the intense paroxysmal character of true bronchial asthma, but necessitates recourse to injections of epinephrin

CASE 8—A man, aged 22, who is now undergoing treatment, has been greatly relieved, although he still declares he is not wholly free He had suffered from asthma since childhood, and showed signs of chronic bronchitis in addition to a greatly deflected septum at its posterior part which completely prevented free drainage This condition was fully corrected by a difficult but successful operation, and he now is receiving a vaccine prepared from his sputum and containing the anaerobic fusiform bacillus among other frequently associated organisms As this patient still resorts to some drug—morphin or cocain—his statements are considered unreliable as to the intensity of his nocturnal dyspnea and the necessity of resorting to his drug and his asthma powders

CONCLUSIONS

1 As illustrated by Case 1, it is believed that cases of bronchial asthma exhibiting evidence of secondary bronchitis with perhaps areas of atelectasis or bronchiectasis are the ones most refractory to treatment

2 If no secondary focus of infection exists in the lungs, the discovery and radical removal of foci elsewhere is likely to relieve the patient

3 If the focus responsible for the protein absorption was in the upper respiratory tract, a coryza or any other condition which occludes the nasal passages, and prevents drainage of secretions may occasion a return of asthma, since the individuals are hypersensitive to foreign proteins

4 Autogenous vaccines prepared from the sputum are of much aid in management, but are a two edged sword, and must be employed with great care, and the patient should be given to understand that treatment *will be long and perhaps uncertain*

5 Vaccines can do no good so long as some other focus of infection than that in the lungs is left unremoved by operation

6 The anaerobic fusiform bacillus has seemed to be the bacterium which exerts special influence in the production of asthma, but this is merely an impression, since only when this organism has been obtained from the sputum and incorporated in the vaccine has the administration of a vaccine been beneficial

REFLEX RETENTION OF URINE*

ARTHUR B CECIL, A B, M D

LOS ANGELES

That the muscles of the bladder may be acted on reflexly so as to prevent the normal act of urination is a common observation This occurs particularly after gynecologic operations, and after operations on the rectum, anus, testicle and even more remote regions That the explanation of some of these retentions is not a reflex nerve action but an actual injury to the nervous mechanism, or the urethra or bladder wall is an undoubted fact

Stoeckel and Ruge,[1] in studying puerperal ischuria, almost invariably found an edematous ring about the internal sphincter Steuernagel[2] thought that some of the cases of retention of urine following labor were due to an increased bladder capacity Thus he found that while the normal bladder would hold only between 450 and 550 c c, the puerperal one could be made to contain under pressure as much as from 1,500 to 2,500 c c And Taussig,[3] in a study of the bladder function after confinement and gynecologic operations, came to the conclusion that the important features in postoperative urinary retention are interference with the blood supply of the bladder, direct or indirect pressure around the sphincter urethrae, excision of the nerve supply of the bladder, and interference with the control of the central nervous system through anesthetics, drugs or mental processes

[1] Stoeckel and Ruge Zystoskopie des Gynäkologen, 1904

[2] Steuernagel Ztschr f Gynak Urol, 3, 295

All of these factors undoubtedly play a part in postoperative retentions of urine, but aside from these cases there is a group of acute retentions which are undoubtedly dependent on reflex phenomena Inasmuch as the large majority of these cases are transitory, very little attention has been given to them, and it is true that most of the cases of urinary retention demanding treatment on account of retention are undoubtedly due to a real mechanical obstruction or to a definite organic nerve disease

In looking over the literature many of the cases of obscure retention were found to give a history of syphilis It is now a well recognized fact that spinal syphilis may manifest itself in the early stages only by vesical disturbances, and it is probable that many of the formerly obscure cases of retention of urine were really early cases of cerebrospinal syphilis

Excluding all of these types of chronic retentions, however, there is still another type which I have chosen for the subject of this paper, and that is, a condition of recurrent attacks of retention with at first intervals of entire freedom from vesical disturbances which are dependent on chronic irritation acting in a reflex manner It is believed that such cases exist without the presence of mechanical obstruction in the sense of an occluding obstruction, without demonstrable nerve lesions and whose mechanism is essentially the same as is seen so commonly following surgical procedures on the nearby structures to the bladder, and that the condition is primarily not necessarily dependent on pathologic changes in the sphincter muscle of the bladder, but is excited reflexly through the spinal cord center

The experiments of Roussy and Rossi[4] have conclusively demonstrated that the center presiding over the bladder function is situated in the conus terminalis They showed that destruction of the conus terminalis resulted in complete loss of sphincter control and bladder function, and that section of the spinal cord above the conus terminalis did not destroy the bladder function, inasmuch as animals in which this had been done very quickly resumed control of the urine so that urine was retained in the bladder for definite intervals and expelled in a normal manner In the adult man this lower spinal center is presided over by the cerebral one so that the act of urination is initiated by a mental process

Retention of urine, or inability to urinate, depending on disturbances of the cerebral control of urination, are very common, and such must be the explanation of the cases of inability to urinate in the presence of another person or in one situation or another

Of these disturbances of urination dependent on the cerebral control there are perhaps many different types, some of which are of the same origin as hysteria, as manifested in other ways, a dissociation, others are only temporary inabilities to carry out the mental process to initiate the urinary act

Frankl-Hochwart[5] mentions an interesting case of the hysterical type in a woman, aged 19, whom for a year and a half it was necessary to catheterize in a hospital, on account of constant retention of urine Examination showed a completely normal condition Finally one of the attendants remarked that an operation would have to be performed, and she immediately recovered

Aldrich[6] has mentioned numerous cases of disturbances of urination dependent on derangements of the higher urinary center In one instance, a physician was never able to urinate in the presence of another person In another instance, the person could not use a public urinal One person could not urinate in a darkened room One could not urinate unless in a darkened room A child found it necessary to count in order to urinate, and so on indefinitely

It is evident that these are not retentions dependent on reflex phenomena acting through the lower urinary center These are truly cases for psychic suggestion, and it matters little whether this suggestion be carried out by local treatments in the region of the bladder or by well recognized treatments for various hysterical conditions, so long as this group of cases of retention of urine is recognized and is definitely treated as such

The conception of a reflex chronic retention of urine excited by some external irritant is by no means a new one Thus Eugene Fuller,[7] in writing on chronic contraction of the vesical neck, speaks of acute spasms of the vesical sphincter excited by pathologic states in the sexual apparatus, the rectum, etc He believes that these acute spasms might become a condition of chronic contraction as a result of some settled disorder of the sexual apparatus or adjoining structures where this reflex spasm had existed as a prominent symptom for a long period of time He found, as he believed, evidences in his cases of a preexisting reflex cause, and likened a chronic contraction of the vesical neck to a chronic torticollis

Swinburne[8] has reported cases of chronic retention of urine which he attributed to a diseased condition of the verumontanum, and thought that the cases of chronic retention which he had studied were closely associated with the cases of acute retention which one sees in acute posterior urethritis

Other cases of retention attributed to irritations in the posterior urethra have been mentioned by Rothschild,[9] Cohn[10] and others

Emodi[11] mentions the case of a man in whom the expulsion of a lumbricoid worm stopped the retention crises, and although the neurologic examination in this case was negative, it is open to question, inasmuch as this patient had previously had syphilis

Reflex spasm with the retention of urine have been attributed to congenital anomalies, phimosis, atresia of the meatus, strictures, foreign bodies, prolonged dilatation of the bladder, inflammation of the kidney (but these may be secondary to cystitis), cystitis, chronic prostatitis, chronic seminal vesiculitis, etc

REPORT OF CASES

The following cases are reported as examples of reflex retention of urine

Case 1—A woman, married, aged 48, was referred to me for urologic examination by Dr William Monroe Lewis of Los Angeles, Aug 12, 1914 She complained of being unable to urinate This difficulty in urinating commenced two years previously when she would have a desire to urinate but would have to strain for some time before being able to pass urine, and a fair amount would then be passed Hot cloths were used to relieve the straining, which seemed to be at the neck of the bladder These attacks of difficulty in urinating would come off and on and then disappear This continued for fifteen months, or nine months before she was seen by me, when she had complete retention and had to be catheterized She was then able to void until three days before admission, when it was again necessary to catheterize her At the same time she noticed a fulness in the left side of the abdomen My examination showed a colon bacillus infection of the urine, a marked acute cystitis, no mechanical obstruction at the neck of the bladder, no trabeculation of the bladder, a complete duplication of the left renal pelvis and ureter, with an infected hydronephrotic sac at the caudal pole This entire left kidney mass was *removed* by Dr Lewis two days later Following the removal of this sac the patient did *not immediately regain the power to urinate*, but had to be catheterized for about two weeks, when all retention disappeared *entirely* and she has been voiding in a normal manner ever since, which has been almost two years In this case it is evident that the retention of urine was directly associated with the hydronephrotic sac, although it is difficult to say as to what part the inflammation of the bladder might have played in bringing about the retention In either case the retention was of a reflex origin

Case 2—A man, aged 40, extremely well nourished was first seen by me, July 17, 1915, complaining of spasms at the neck of the bladder, attacks of great difficulty in passing urine, and occasionally having to be catheterized When 19 years of age he had had gonorrhea complicated by a double epididymitis, and since then two attacks of urethritis at the ages of 27 and 35 years, respectively The latter two attacks of urethritis followed periods of drinking, lasted for only about ten days, and no gonococci were found in the discharge The patient denied syphilis The urinary stream, except when he had periods of retention, was of good size and force Ejaculation was somewhat premature, the sexual power otherwise was negative The present illness began about four years previous to admission, when he felt as if he wanted to void but could not until his bowels had moved at which time he voided freely At the same time he noticed that on arising in the morning he frequently had a sharp pain running from the prostate to the head of the penis This pain was relieved by urination These attacks of pain were accompanied by marked frequency of urination, but it was often necessary for him to go to stool in order to pass urine There was marked hesitancy, but after the attacks passed off the stream would be of normal size and force About four months later he had an attack of acute retention and had to be catheterized He was diagnosed at this time as having a urethral stricture and later as having contracture of the vesical neck A punch operation was done, but this did not help him The patient then took a complete rest at one of the springs, and had no bladder disturbances whatever for several months When first seen by me he had *complete retention, but the bladder was not* markedly distended He complained of violent pain at the neck of the bladder, *a spasm*, as he himself called it Hot tubs did not relieve him A catheter was somewhat difficult *to pass through the internal sphincter*, which was definitely *in a spasm* About 300 c c of urine were withdrawn It was then necessary to catheterize him three times within the next twenty-four hours, although there were urinations in which he passed urine with perfect freedom The urine was negative

Briefly, then, the history of this case is one of attacks of complete retention occurring *in a healthy man*, aged 40, associated with spasmodic pain at the neck of the bladder, radiating to the head of the penis In the intervals between the spasmodic attacks of pain, urination would be perfectly normal, and there would be months of entire freedom from any vesical disturbances Following hard mental work, a sudden complete, spasmodic, painful retention would occur The Wassermann test of both the blood and spinal fluid was negative Roentgenoscopy of the vertebral column was negative Neurologic examination by a competent neurologist was negative Urologic findings showed prostate of normal size with slight induration of both lobes The prostate was not enlarged, nor was it smaller than normal when examined by rectum The right seminal vesicle was indurated and adherent externally The left seminal vesicle was also indurated There was a perivesicular induration and an induration extending between the two seminal vesicles The prostatic secretion showed 10 per cent pus On cystoscopic examination the patient having complete retention, the bladder capacity was difficult to determine The bladder wall was not trabeculated The trigon seemed hypertrophied, the posterior margin quite prominent There was a slight elevation of the posterior portion of the internal urethral orifice, and a slight rounding of this orifice anteriorly

The question arose in this as to the possibility of a contracture of the vesical neck *The history is against this* He had not progressively grown worse, in fact, for *six months previous to the time when I saw him, he had not* had any frequency of urination or any difficulty whatever *in passing urine* There would be *months of entire free*dom from any vesical disturbances, and then following hard work, or *things which tended to make him run down, he* would have attacks of violent spasm at the neck of the bladder with acute retention The very next urination would *at times* be perfectly normal The spasm of the internal sphincter *was so great as to interfere* with catheterization The very violence of the attacks of retention is against a long standing constantly acting mechanical obstruction It is believed that this is a case not dependent on any definite organic obstruction but on a spasm of the internal sphincter muscle probably reflexly excited by a seminal vesiculitis

Case 3—A man, aged 28, married for six years, was first seen by me, March 31, 1915 He complained of periods in which he was unable to urinate, and at these times it was necessary for him to use a catheter Until the age of 20 he was a healthy man, did not have to get up at night to urinate, and had no difficulty in passing urine About eight years before admission he started getting up at night to urinate, about once, early in the morning He was married two years later, and about a year after marriage he commenced to notice burning on urination Four years before admission he was taken with complete retention and had to be catheterized He would then have periods in which he would urinate in a normal manner and others in which it would be necessary for him to catheterize himself In July, 1912, he was studied by a urologist, and in 1913, a suprapubic cystotomy was done Apparently nothing was found The bladder was sewed up and quickly healed For four months then he got along very well, voiding urine without catheterization He then commenced to have spasmodic pain on voiding He was again studied and told that the *verumontanum* was greatly enlarged This was cauterized with some relief from pain, which seemed to be *in that region*, but during 1914 it was occasionally necessary for him to catheterize himself, on *account of retention of urine For three weeks previous to* admission he used a catheter practically every time the *bladder felt full* The *history of this catheterization is rather* peculiar At times it was only necessary to pass a catheter a very short distance into the urethra, when he was able to urinate, at others it was necessary to pass the catheter all the way into the bladder, but not necessary to leave it there, for the catheter could sometimes be withdrawn and he would continue to empty the bladder through the urethra with a large size stream

The course of events in his retention he described as follows On attempting to urinate, an intense burning at the neck of the bladder occurred, and the muscle then seemed to go into a spasm and shut off the urine At times some would be passed, and then the bladder seemed to shut off with a grating sensation, and he was unable to relax it There was no history of syphilis He denied gonorrhea Examination showed a fairly well nourished young man, with normal reflexes The Wassermann test of the blood and spinal fluid was negative Roentgenoscopy of the vertebral column was negative Rectal examination revealed a prostate of about normal size The prostate showed marked induration along the left outer border, and slight induration of the right lobe The left seminal vesicle was greatly indurated, and stood out like the finger of a glove The right seminal vesicle was thickened, but not as much so as the left The prostatic secretion showed 50 per cent white blood cells In spite of the numerous times which the patient had catheterized himself, the urine was not infected and was otherwise negative Just before cystoscopic examination was done the patient had catheterized himself, and when cystoscopy was performed, 50 c c of urine were found in the bladder The bladder capacity was 160 c c The bladder wall was not trabeculated, but the interureteric band was greatly hypertrophied and stood up as a ridge across the bladder As the cystoscope was withdrawn into the urethra, no posterior bar was seen, and all of the prostatic views were concave Anteriorly the scar of the operation spoken of above was seen The urethra was very carefully studied with an endoscope with negative findings This patient was treated by prostatic massage and massage of the seminal vesicles Following this treatment extending over a period of three months he was able to dispense with his catheter improved greatly in general health and the spasms at the neck of the bladder ceased It is thought that this case is an example of a spasmodic retention of urine depending on inflammation of the seminal vesicles It was cured by attention being given to these diseased organs

MECHANISM OF RETENTION

What is the mechanism of reflex retention of urine? Is it an inhibition of the detrusor muscle of the bladder, is it a spasm of the sphincter muscles of the bladder, or is it an inability to inhibit the normally contracted sphincter muscle?

In regard to the first possibility, an inhibition of the detrusor muscle of the bladder, Albarran and Nogues[12] have regarded this as the most likely possibility in functional retention of urine extending over a long period of time While they did not doubt the occurrence of spasms of the muscles occasionally being responsible for the retention of urine, they regarded it as rather unusual To quote from them

> We think that the sphincter troubles capable to determine prolonged retention of urine are especially produced when the normal faculty of inhibition, reflex or voluntary, is lost We also think that most often these disturbances of inhibition have not to do with the sphincter apparatus for their exclusive seat, but that they act also on the contractibility of the bladder

In this connection the various theories as to the mechanism of cardiospasm are of interest In this condition there can be no question as to the absence of organic obstruction, and yet the obstruction is most complete

Morrell Mackenzie[13] believed that it was due to the general weakness of musculature of the esophagus Mikulicz[14] believed that the spasm of the cardia was responsible for it, and Hertz[15] and Rolleston,[16] from the fact that the muscle at the cardiac orifice is practically never found to be hypertrophied, regarded the condition as due to the inability to relax or inhibit the normally contracted cardiac orifice—an acalasia

Hertz,[17] however, found one case in which there was a definite spasm at the cardiac sphincter and Mathieu and Roux[18] described a case in which it was impossible to withdraw an esophageal sound until the patient had been anesthetized with chloroform, so that it will be seen that the same views are held in connection with cardiospasm as have been held responsible for functional retention of urine That the functional retention of urine is not due to an inhibition of the detrusor muscle, as was supposed by Albarran, would seem to be true in the cases which I have cited When the catheter was passed into the bladder, urine was forced out with considerable force Moreover, the retention of urine was quite painful and was spasmodic The condition is not due to a spasm of the external sphincter muscle, nor is this muscle necessarily associated with the retention

The work of Volcker and Lichtenberg,[19] Leedham-Green,[20] Barringer and MacKee,[21] and Uhl and MacKinney[22] has conclusively demonstrated that urine is retained in the bladder under normal conditions by the internal sphincter muscle It is commonly supposed that the external sphincter muscle works constantly in unison with the internal sphincter muscle, which is by no means the case Ejaculation may take place with the bladder full of urine without urine escaping, in which case it is evident that the internal sphincter muscle must be contracted and the external sphincter muscle relaxed If the prostate be massaged with the bladder full of urine, prostatic secretion can be expressed from the urethra without urine escaping

In the cases of spasmodic retention of urine cited above, it was definitely determined that the retention took place at the internal sphincter muscle As to the two remaining possibilities, as to whether this type of retention is due to a spasmodic condition of the internal sphincter or an inability to inhibit a normally contracted muscle, it would seem that both of these conditions might be a possibility, but in the cases which I have observed, some urine would usually be passed, when the muscle would seem to be thrown into a spasm

TREATMENT

In regard to the treatment of this condition, an attempt should be made to find the exciting cause In Case 1, the removal of the hydronephrotic sac resulted in a cure of the disturbances of the normal mechanism of urination which had extended over a period of almost two years In Case 3, massage of the seminal vesicles resulted in a cure, whereas a catheter had been necessary for most of the time over a period of four years It is a question as to whether this condition could become a settled one and produce permanent changes in the sphincter muscle such as Fuller has described If this occurs, it is probable that section or division of the internal sphincter muscle would be required for relief of the condition, and in the persistent cases this method of treatment would possibly be advisable

This condition must be differentiated from contracture of the vesical neck due to fibrous tissue changes

OBSERVATIONS ON CERTAIN OBSTRUCTIONS AT THE VESICAL ORIFICE *

OSWALD S LOWSLEY, AB, MD
NEW YORK

The subject of obstructions at the vesical orifice with attendant distressing symptoms has occupied the attention of surgeons for many generations Interest in this particular field of urology has been much stimulated recently by the fact that cystoscopic examinations have become a routine procedure in cases of patients who are suffering from urinary disturbances

In urology as in other fields of medical science the progressive surgeon is alert to discover early pathologic conditions in order that relief may be prompt and effective, thereby eliminating much suffering and repairing damaging conditions

In this discussion it seems advisable to consider vesical orifice obstructions other than those caused by enlargement of the prostate gland proper which is believed to be a subject apart

The older writers recognized several types of vesical orifice obstructions Sir E Home[1] described what we now know to be hypertrophy of the subcervical group of Albarran as the normal middle lobe of the prostate His view was much and justly criticized by his contemporaries, and in fact the condition was correctly described by writers much before his time Morgagni[2] in 1761 referred to this condition as a morbid growth causing retention of urine He considered it to be of the same nature as the prostate gland and contiguous with it Valsalva, Pohlius, Santorini,[3] Thomas Bartholin of Padua, and Valisneri described similar growths, and were quoted by Morgagni and Bonetus[4] as early as 1700 to the effect that excrescences grew out in the very middle of the internal and upper circumference of the gland, posteriorly, in some old men Lieutaud, a contemporary of Morgagni, considered an eminence at the neck of the bladder to be not a morbid growth, but a small part quite natural and common to all bodies He called it the "uvula vesicae" John Hunter[5] agreed with the opinion of Lieutaud J Cruveilhier[6] and Langenbeck considered a protuberance in this region to be pathologic and that there was no definite middle lobe but a middle portion

Valpeau[7] mentioned fibrous prostatic tumors, "which develop in the direction of the vesical cavity, which become absolutely pedunculated precisely as do the fibrous polypi of the uterus, and become enveloped by the vesical mucous membrane" Rokitansky[8] considered such tumors and their relation to the prostate to be analogous to tumors of the thyroid gland and outlying formations similar in structure to it Sir J Paget[9] agreed with this view, as did also Sir W Fergusson,[10] Mr Shaw[11] and Sir Henry Thompson[12]

Mr J G Guthrie in 1830 lectured on prostatic and nonprostatic obstructions at the vesical orifice He concluded that (1) an elastic structure exists at the neck of the bladder and may be diseased without any necessary connection with the prostate gland, (2) the prostate gland may be diseased without any necessary connection with the elastic structure Mr Guthrie first used the term "bar at the neck of the bladder," and distinguished between it and the obstruction caused by the large median portion of the prostate proper Civiale[13] describes the "vesico-urethral barrier" as formed in some cases by "a simple fold of membrane, smooth and thin, and almost transparent, extending from one lobe of the prostate to the opposite" and others by fold, thicker, in the form of a rounded cord which contains some fibrous or muscular tissue He also mentions that obstruction in the region of the vesical orifice may be due to spasmodic muscular contractions, rheumatism, etc Mercier[14] does not entirely agree with the views of Guthrie, but describes a "semiannular eminence" He recognizes two distinct kinds, one produced by repeated spasm of the muscular fibers which close the neck of the bladder, becoming a permanent bar, the other a result of hypertrophy of the median portion of the prostate

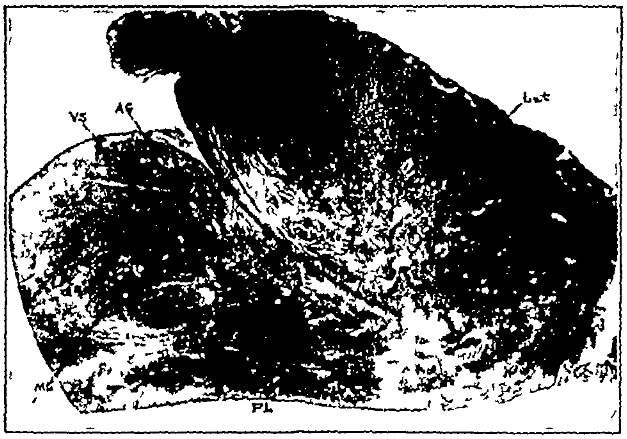

Fig 1—Oblique section through the prostate and trigonal region of a man aged 76 *Ur* urethra *AG* subcervical gland tubules *VS* vesical sphincter *ML* middle lobe tubules *EJD* ejaculatory ducts and muscular envelope *PL* posterior lobe tubules *Lat* lateral lobe tubules

Sir Charles Bell[15] believed that hypertrophy of the middle lobe was caused by the pull exerted on it by the muscle bands of the trigonum vesicae in irritative conditions of the bladder The work of G V Ellis[16] on the anatomy of this region proved that the muscles of the trigon are attached to the longitudinal muscular coat of the urethra and hence do not react in the manner described by Bell

Albarran[17] describes in detail a group of glands at the vesical orifice which open into the urethra and whose tubules lie between the mucosa and the musculature He calls this the subcervical glandular group and states that it varies greatly in different individuals and may be entirely lacking in some Cuthbert S Wallace[18] states that in a certain number of cases while circular muscle fiber is still well marked and forming a very definite barrier between the gland tissue behind and the urethra in front, there can be seen lying close under the mucous membrane prostatic glandular alveoli which may give rise to the small adenomatous tumors situated just within the internal meatus in some cases

Dittel[19] maintains that the hypertrophic middle lobe does not project behind the sphincter into the lumen of the bladder, but originates from the "portia intermedia" in front of the sphincter and encroaches during the growth between the mucous membrane of the urethra and posterior half ring of the sphincter, by which procedure the sphincter comes to lie behind as a tumor functionating like a valve Jores states that valvelike tumors of the orifice take their origin not from the prostate gland itself, but from the glandular tissue, which is already normally present, "in most individuals above the colliculus seminalis" just below the mucous membrane of the urethra and orificium, respectively, at any rate, in front of the sphincter Ciechanowski[20] agrees with the view expressed by Jores

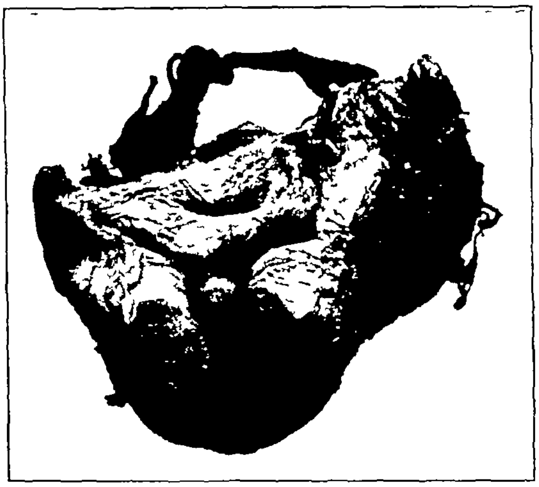

Fig 2—Moderate unilobular hypertrophy of subcervical group with a raised contracted trigonum vesicae and a moderately deep bas fond Bladder shows signs of obstruction

Anatomic conditions at the vesical orifice have been extensively studied by the author[21] The small group of subcervical tubules which seem to have attracted so many writers has proved to be most interesting These tubules begin to develop at the fourth intra-uterine month and are found in every specimen older than that They are not particularly numerous up to the time of birth, as there are never more than eleven After birth they increase greatly so that in one specimen there are as many as forty-three The average number for all specimens is twenty-five Structurally they differ from prostatic tubules in a number of important details There is not a differentiated layer of muscular and connective tissue fibers around them, although in disease the fibrous tissue develops an encircling sheath in many instances The mucosa is composed of two or three layers of low columnar or cuboidal epithelial cells, chiefly the latter, placed on a feltlike basement membrane The nuclei are usually in the center of these cells and almost never occur near their bases as they do in the cylindric cells of prostatic mucosa Many of these nuclei are oval in contour The lumina are small and usually circular or oval in shape and rarely have an irregular outline with fingerlike projections as do the prostatic tubules These tubules in an adult resemble the tubules of an embryonic prostate gland to a considerable degree

The subcervical group of tubules located, as its name signifies, at the vesical orifice, chiefly in the mucosa of its floor, is subjected to many influences which tend to make the occurrence of pathologic conditions rather frequent In fact, a careful study of some 350 prostates collected from routine necropsies shows an enlargement of this group in about 25 per cent of patients over 30 years of age In practically all cases of adenomatous hypertrophy of the prostate there is an accompanying enlargement of the subcervical group of considerable degree Therefore it is assumed that the same factor which causes an adenomatous hypertrophy of the prostate also stimulates an overgrowth of the subcervical group of tubules, and furthermore it is believed that the latter structure responds to this stimulating influence before the prostate itself does

The enlargement of the subcervical group of tubules occurs in several forms The most frequent is the small single tumor which occurs in the midline at the vesical orifice and usually projects through the internal meatus into the bladder This structure was observed by the older writers and apparently occurred with great frequency in 1700, as it was described at that time by the venerable French writer Lieutaud, who considered it a normal structure and called it the "uvula vesicae" Next in frequency of occurrence are the medium sized single tumors Very many cases of extensive adenomatous hypertrophy of the prostate are accompanied by an intravesical intrusion of the subcervical group of tubules, and this tumor is frequently mistaken for an enlargement of the middle lobe which is, as a matter of fact, usually adenomatous in type but rarely protrudes into the bladder, although it often lifts the lower portion of the trigonum vesicae In almost every instance careful examination of the adenomatous prostate removed intact shows a groove where the vesical sphincter has compressed the enlarged subcervical group which projects into the bladder, and which is removed with the prostate in the suprapubic operation

In addition to the single tumors of various sizes there are a number of enlargements of this group which are partially divided This division seems to be caused by a rather strong development of the bundles of muscle and connective tissue which extend from each ureter to the musculature of the posterior urethra, the so-called "Bell's muscles" These structures in some instances are more unyielding than in others, and hence cause a lack of development at their strongest points, thus dividing partially or completely the group into several parts, usually three Sometimes the division is so complete that the entire

OBSERVATIONS ON CERTAIN OBSTRUCTIONS AT THE VESICAL ORIFICE*

OSWALD S LOWSLEY, AB, MD
NEW YORK

The subject of obstructions at the vesical orifice with attendant distressing symptoms has occupied the attention of surgeons for many generations Interest in this particular field of urology has been much stimulated recently by the fact that cystoscopic examinations have become a routine procedure in cases of patients who are suffering from urinary disturbances

In urology as in other fields of medical science the progressive surgeon is alert to discover early pathologic conditions in order that relief may be prompt and effective, thereby eliminating much suffering and repairing damaging conditions

In this discussion it seems advisable to consider vesical orifice obstructions other than those caused by enlargement of the prostate gland proper which is believed to be a subject apart

The older writers recognized several types of vesical orifice obstructions Sir E Home[1] described what we now know to be hypertrophy of the subcervical group of Albarran as the normal middle lobe of the prostate His view was much and justly criticized by his contemporaries, and in fact the condition was correctly described by writers much before his time Morgagni[2] in 1761 referred to this condition as a morbid growth causing retention of urine He considered it to be of the same nature as the prostate gland and contiguous with it Valsalva, Pohlius, Santorini,[3] Thomas Bartholin of Padua, and Valisneri described similar growths, and were quoted by Morgagni and Bonetus[4] as early as 1700 to the effect that excrescences grew out in the very middle of the internal and upper circumference of the gland, posteriorly, in some old men Lieutaud, a contemporary of Morgagni, considered an eminence at the neck of the bladder to be not a morbid growth, but a small part quite natural and common to all bodies He called it the "uvula vesicae" John Hunter[5] agreed with the opinion of Lieutaud J Cruveilhier[6] and Langenbeck considered a protuberance in this region to be pathologic and that there was no definite middle lobe but a middle portion

Valpeau[7] mentioned fibrous prostatic tumors, "which develop in the direction of the vesical cavity, which become absolutely pedunculated precisely as do the fibrous polypi of the uterus, and become enveloped by the vesical mucous membrane" Rokitansky[8] considered such tumors and their relation to the prostate to be analogous to tumors of the thyroid gland and outlying formations similar in structure to it Sir J Paget[9] agreed with this view, as did also Sir W Fergusson,[10] Mr Shaw[11] and Sir Henry Thompson[12]

Mr J G Guthrie in 1830 lectured on prostatic and nonprostatic obstructions at the vesical orifice He concluded that (1) an elastic structure exists at the neck of the bladder and may be diseased without any necessary connection with the prostate gland, (2) the prostate gland may be diseased without any necessary connection with the elastic structure Mr Guthrie first used the term "bar at the neck of the bladder," and distinguished between it and the obstruction caused by the large median portion of the prostate proper Civiale[13] describes the "vesico-urethral barrier" as formed in some cases by "a simple fold of membrane, smooth and thin, and almost transparent, extending from one lobe of the prostate to the opposite" and others by fold, thicker, in the form of a rounded cord which contains some fibrous or muscular tissue He also mentions that obstruction in the region of the vesical orifice may be due to spasmodic muscular contractions, rheumatism, etc Mercier[14] does not entirely agree with the views of Guthrie, but describes a "semiannular eminence" He recognizes two distinct kinds, one produced by repeated spasm of the muscular fibers which close the neck of the bladder, becoming a permanent bar, the other a result of hypertrophy of the median portion of the prostate

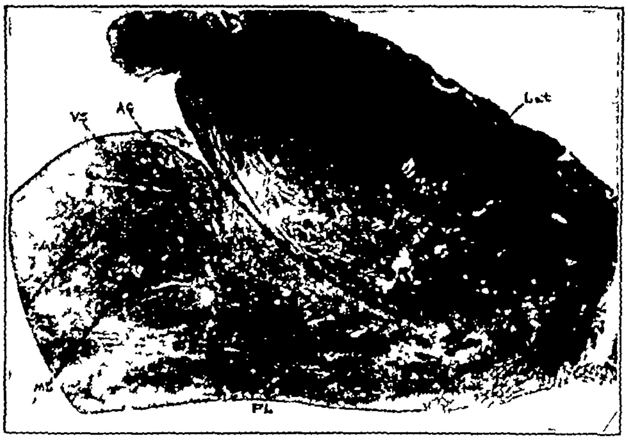

Fig 1—Oblique section through the prostate and trigonal region of a man aged 76 *Ur* urethra *AG* subcervical gland tubules *VS* vesical sphincter *ML* middle lobe tubules *EJD* ejaculatory ducts and muscular envelope *PL* posterior lobe tubules, *Lat* lateral lobe tubules

Sir Charles Bell[15] believed that hypertrophy of the middle lobe was caused by the pull exerted on it by the muscle bands of the trigonum vesicae in irritative conditions of the bladder The work of G V Ellis[16] on the anatomy of this region proved that the muscles of the trigon are attached to the longitudinal muscular coat of the urethra and hence do not react in the manner described by Bell

One other type of subcervical tumor occurs, namely, the horseshoe shaped tumor. This type is generally fairly large and usually encompasses the lower half of the circumference of the internal meatus. Obstruction to urination occurs in this type, and may be complete, but is ordinarily partial. The act of micturition in this instance may be and usually is accompanied by considerable pain. In one interesting case in my practice the patient had been operated on for an adenomatous prostate by Young's perineal method, after which his complete retention became partial, there being 12 ounces of residual urine after his micturition, which occurred as a very painful dribbling. Cystoscopic examination showed a horseshoe shaped enlargement of the subcervical group of tubules which was a little more extensive on the left than on the right. The tumor was removed by Young's punch with thorough relief of pain, a good strong stream of urine and less than 1 ounce of residual urine.

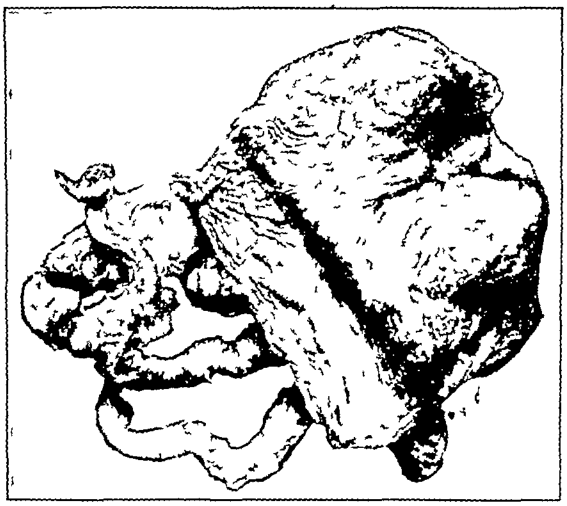

Fig. 3.—Enlargement of subcervical group in the shape of a very thick letter U extending from the upper end of the verumontanum within the sphincter and into the bladder which shows signs of obstruction.

Hypertrophic changes in the trigonal musculature come next in frequency as a cause of the obstruction at the vesical orifice to urinary outflow. In a series of cases recently reported, seventeen cases with sufficient hypertrophy to cause considerable obstruction to urinary outflow were found which made up 7.6 per cent. of the entire number observed. This condition almost never occurs before the fortieth year. It is accompanied by a very deep posttrigonal pouch or bas fond.

The subtrigonal group of tubules which is found in all specimens between the middle of the trigonum vesicae and the vesical orifice is frequently the seat of pathologic change. The most frequent lesion is ulceration, but sometimes there are found tumors which are a source of obstruction. These tumors are of three kinds. The most common is the low mound shaped mass which sometimes does and again does not cause obstruction. Rarely if ever does this type not cause complete retention. Next in frequency is the pedunculated mass which is an outgrowth from this group of tubules, and, situated as it is just above the vesical orifice, often acts as a ball valve and may cause complete retention of urine. Dr. Hugh H. Young of Baltimore reports several such cases, and I have observed a number of others through the cystoscope. Villous papillomas occur in this region occasionally and may even be found just at the vesical orifice, as Joseph F. McCarthy has observed.

Fibrous stricture of the vesical orifice is not an infrequent source of obstruction to urinary outflow. This is usually a result of chronic inflammatory process, but may follow operative procedure in this region.

A specimen showing marked stricture of the vesical orifice was sectioned and cut both longitudinally and laterally and stained according to van Gieson's method and also with hematoxylin and eosin. A brief description follows. The mucosa of the apex of the trigonum and the vesical orifice is composed of several layers of epithelial cells transitional in type. The smooth muscle bundles of the trigonum vesicae are well shown as fine fibrils superimposed on the rather coarser bundles forming the vesical wall proper. At the apex of the trigon these muscle bundles seem to be firmly and closely matted together. Numerous blood vessels of moderate size are found throughout this region. They are, in fact, much more numerous here than at any other portion of the structure. Proliferation of the connective tissue cells has taken place, and there is marked small round cell infiltration. This increase in fibrous tissue is most marked in the layer which is continuous with the trigonum vesicae and above and toward the bladder lumen from the subcervical group of tubules. Extending downward from the trigonal region at several points are observed quite marked bundles of tissue which insinuate themselves between the fibers composing the wall of the bladder proper, and these serve to bind the two structures together quite firmly. The subcervical tubules of Albarran are considerably atrophied in appearance. The mucous membrane lining the tubules is composed of cuboidal shaped cells, usually one layer in thickness placed on a feltwork base. There is considerable infiltration of small round cells in the region of these tubules and also about the muscle bundles of the sphincter which lie just beneath them. The entire picture gives one the impression of fibrosis due to long continued low grade inflammation.

Cysts at the vesical orifice are occasionally met with, and in some instances are the cause of grave obstruction. They usually occur just within the vesical sphincter and probably arise from the subcervical tubules. Rarely, however, they may spring from the subtrigonal group. One which occurred in my series gave rise to very marked obstruction with retention of urine and trabeculation of the fundus of the bladder.

DIAGNOSIS

The diagnosis of the above conditions is based on the following findings. There is often a certain amount of pain, even in the earlier stages. Sometimes it becomes exceedingly acute and in other instances may be merely a feeling of uneasiness when the bladder becomes full or is being emptied. Very often the patient has a feeling that he is not able to completely empty his bladder. In the worst cases the symptoms may resemble those of the prostatic. There is always residual urine. Often in early cases this will not exceed an ounce. In a case of moderate degree it usually amounts to 4 or 5 ounces, and in the more advanced cases complete retention results.

The passage of bougies and sounds reveals to the careful manipulator the fact that stricture is not the cause of the patient's trouble, and just as the instrument passes into the bladder the sense of riding over an obstructive mass at the vesical orifice is transmitted. Catheterization reveals the amount of residual urine.

On rectal examination the prostate will usually be found to show evidence of chronic irritation It frequently is indurated and nodular, and usually there are numerous bandlike adhesions extending from the lateral surfaces and between the base and the seminal vesicles These vary in their firmness The most important thing to be learned from the examination of the prostate in these cases is that it does not show marked enlargement With an instrument in the urethra and the finger in the rectum changes of the collarlike vesical sphincter are readily appreciated

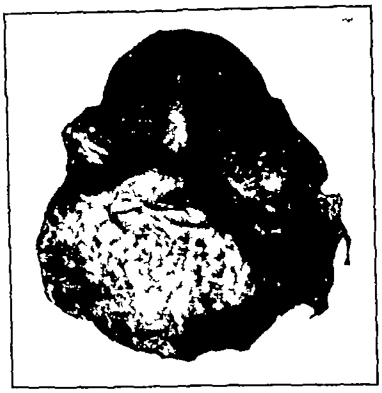

Fig 4—Trilobe enlargement of subcervical group with marked signs of obstruction

Cystoscopic examination, preferably with the McCarthy straight instrument or the Buerger urethroscope, is the most important examination to be made in arriving at a diagnosis in these cases There is usually hypertrophy of the musculature of the bladder wall so that trabeculation in the fundus is quite marked, cellules occurring frequently, sometimes being quite deep

The trigonum vesicae is in most instances somewhat hypertrophied, particularly in the interureteric region, thus forming a rather deep posttrigonal pouch The ureteral orifices are situated on quite marked ridges owing to the trigonal hypertrophy and are not necessarily changed, although they may be dilated from back pressure in aggravated cases

The vesical orifice is of course the most interesting part of the picture Tumor masses arising from the subtrigonal group are easily recognized, as are those which originate from the subcervical tubules It is sometimes necessary in the case of the latter to depress the eyepiece of the cystoscope considerably in order to throw the vesical orifice into the field more satisfactorily Very early tumors on the floor of the internal meatus are recognized by the change from the normal concave border to a convex mass which projects itself into the field Multiple, cystic, pedunculated and horeshoe shaped tumors are distinguished by careful observation

Fibrous strictures of the vesical orifice present slightly greater difficulties in the matter of diagnosis Often in these cases there may be some slight difficulty in introducing the instrument, and frequently there is considerable pain The vesical orifice presents concave borders over its entire circumference Observation of the apex of the trigonum vesicae shows a very steep proclivity, so that if it is to be observed closely the eyepiece of the instrument must be very much elevated Also in observing that portion of the urethra between the vesical orifice and the upper end of the verumontanum a marked declivity is noted and the eyepiece of the instrument must be considerably lowered

An early diagnosis of these interesting conditions at the vesical orifice is extremely important, just as is an early diagnosis in tuberculosis, carcinoma or any other serious condition Although obstruction to urination is not such an emergency affair as appendicitis, it is most important that immediate measures be adopted to relieve the obstruction The harmful results of residual urine with the possibility of back pressure in ureters and kidneys, of easy infection, the formation of stone, etc, are too well known to require a lengthy description in this article

TREATMENT

In very early cases of enlargement of the subcervical group of tubules there are usually few if any symptoms As the condition becomes more aggravated there may develop a burning pain on micturition, a disturbance in the force and character of the stream, and a sense of fulness in the perineum and various referred pains down the insides of the thigh, in the small of the back, etc The patient may also have a sensation that he is not completely emptying the bladder Catheterization shows a small amount of residual urine In very early cases only 20 or 30 c c may remain after micturition

In these early cases the administration of hexamethylenamin with acid sodium phosphate or sodium benzoate will render the urine antiseptic, and as there is usually a considerable amount of inflammatory tissue in and around these tumors, the burning and referred pains are frequently relieved by instillations of arygrol, or weak solutions of silver nitrate The passage of sounds with occasional massage of the regions of the vesical orifice by rectum on the collarlike mass which is felt with the sound in place will sometimes give relief These and various other palliative measures give temporary relief, but as the fundamental cause of the symptoms is the hypertrophy of the subcervical group and not the inflammation accompanying it, in the end the symptoms become more pronounced and recur as the tumor enlarges

Occupying, as these tumors do, an extremely strategic position within the sphincter on the floor of the vesical orifice, it is found that as the size increases the obstruction with accompanying evils likewise increases markedly, and steps for removal should be taken

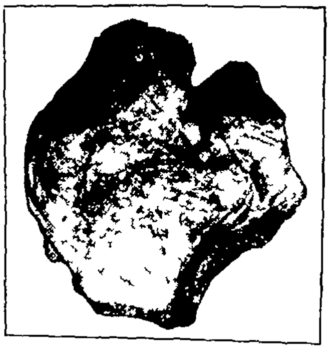

Fig 5—Hypertrophy of subcervical group in three distinct portions which practically block the urethra

A great many procedures have been recommended I have found that Young's punch operation is decidedly the best method employed in removing these intrasphincteric masses, be they small, large, unilobular, or trilobular The instrument is introduced so that the fenestrum is in the posterior urethra The obturator is withdrawn and the instrument inserted still further until the tumor at the vesical orifice rises into the fenestrum, completely filling it The cutting inner tube is then introduced and quickly pushed into position, punching out the entire portion of the tumor in the fenestrum The instrument is then turned obliquely to the right and then to the left, where the same procedure is repeated The instrument is then withdrawn and a catheter with a large fenestrum introduced It is wise to keep a small amount of fluid in the bladder continually, but the former practice of keeping up continuous irrigations has been given up as it seems to delay the clotting of the blood at the cut surfaces and hence delays the healing As a rule the bleeding stops after a few hours, and the catheter can often be removed after twenty-four or thirty-six hours

An enlargement of the subcervical group is of such frequent occurrence that digital examination should always be made when a patient is operated on for enlargement of the prostate by the perineal route

This particular case typifies many others that have come under my observation, and teaches that no prostatectomy is well done unless one searches for a subcervical glandular enlargement at the time of operation

The suprapubic prostatectomy as practiced by Squier will remove the subcervical group of glands in the natural course of the operation

The same influences which cause the subcervical gland to enlarge apparently cause prostatic hypertrophy later on, so the punch operation may be followed years after by a prostatectomy It seems advisable however, to do this operation in every case which presents symptoms and has any considerable amount of residual urine

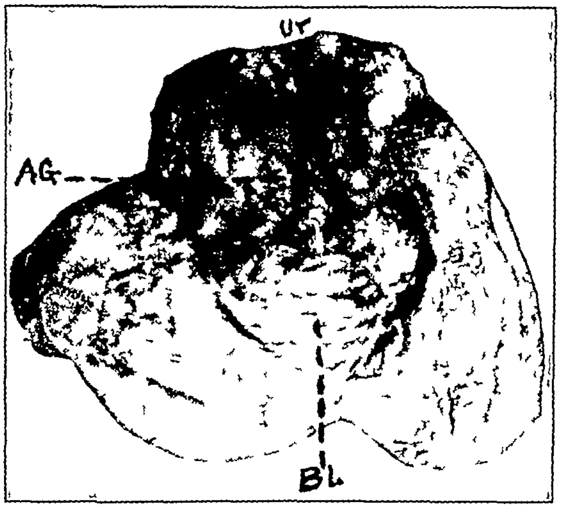

Fig 6 —Specimen showing marked hypertrophy of subcervical group in three distinct portions which are very large and almost completely block the urethra *BL*, fundus of bladder showing marked signs of obstruction *AG* subcervical glands divided into three portions *UR* urethra at apex of prostate

These tumors have been treated by Stevens and others by the high frequency current with splendid results in some instances When treated in this manner the patients should be kept under close observation for several days as the procedure is sometimes followed in three or four days by terrific hemorrhage due to separation of a slough As pointed out by McCarthy, occasionally application of the high frequency current has been followed by severe infection Chetwood's[22] modification of Bottini's[23] operation is also preferred by some operators The reason why the Young's punch operation seems to be the one of choice in this condition is that the entire tumor is removed at one time without injury to the internal sphincter and without requiring the use of a general anesthetic

Hypertrophic changes in the musculature of the trigonum vesicae, as it passes over the floor of the vesical orifice, is best treated by Young's punch operation or Chetwood's electrocautery procedure The high frequency current is of very doubtful benefit, as the resulting scar would be nearly as hard to deal with as the original condition In some of these cases a course of dilatation with sounds will sometimes give relief The reason for this is twofold In the first place the hypertrophy often occurs because of stricture of the urethra, and the passage of sounds relieves the causative element In the second place, there is a great amount of inflammatory tissue present as a rule which is largely dispelled by the passage of sounds Often the action can be hastened by digital massage by rectum in the region of the vesical orifice with the sound in the urethra

Tumors of the subtrigonal group, if not too large, may be removed by Young's intravesical rongeur, which is an exceedingly valuable instrument but must be used with care and intelligence as it is so powerful that if used recklessly there is a possibility of lacerating the vesical wall It has the advantage of sufficient strength and size to enable the operator to excise a large sized tumor without the use of a general anesthetic Buerger's operating cystoscope may be utilized if the tumor is very small The high frequency current has a distinct value in some of these cases, especially if the tumor is pedunculated If the growth is large and sessile it is sometimes necessary, as it was in one case that I saw in Young's clinic, to do a cystotomy and excise the mass with a scalpel

Cases of fibrous stricture of the vesical orifice are treated best by Chetwood's electrocautery and Young's punch Were it not for the fact that an anesthetic is required for the former procedure, it would be decidedly the operation of choice I have in my series a case treated by Chetwood's method with a perfect result The criticism that there is danger of burning into the rectum is not justified, since the distance from the vesical orifice through the prostate to its posterior surface is in all my specimens an inch or more This operation burns through the internal sphincter, and in healing apparently does not permit that structure to resume its physiologic action Incontinence does not occur, however, if the external sphincter is not injured in performing the external urethrotomy to introduce the instrument Young's punch is used in these cases, but is not quite so radical as the Chetwood operation and must be followed by sounds occasionally It has the advantage of not requiring the general anesthetic and of permitting a more rapid convalescence

Cysts at the vesical orifice are best treated by the high frequency current One application of the spark is usually all that is required to eradicate the delicate wall The Buerger operating instrument in a McCarthy's cysto-urethroscope can also be used successfully in this condition Often cysts in this region arise from a portion of the subcervical group, in which case the remainder of the enlargement must be treated as well, although the cystic portion is usually found to be the major portion of the obstructing mass

SUMMARY

Most writers express the opinion that the majority of tumors at the vesical orifice are composed of prostatic glandular tissue My work on the anatomy of this region has shown that glandular tissue extending into the bladder from the floor of the orifice can only be composed of tubules of the subcervical group because the vesical sphincter which is quite thick on its posterior aspect is interposed between these tubules and those of the middle lobe of the prostate Normally the tubules of this group have small lumina The mucous membrane is made up of two or three layers of low columnar or cuboidal epithelial cells with the nuclei in the center These cells are disposed on a feltlike basement membrane There is never a differentiated muscular layer around the tubules, but rarely there is a fibrous tissue envelope

Structurally they resemble in the adult, when normal, the embryonic prostatic gland tubules In pathologic specimens the tubules are increased in number and size The lumina are somewhat larger The mucous membrane retains its usual appearance, except that occasionally tonguelike projections of slight degree extend into the lumina The cells usually retain their cuboidal shape with the nuclei in the center, although rarely there are found some cells which approach the cylindric type There is usually a fibrous tissue development around the tubules, but it is easily differentiated from smooth muscle by the use of Van Gieson's stain The small size of the tubules, the mucosa made up of several layers of cells, and the lack of differentiated tissue around the tubules have led to the mistaken impression that these tubules are composed of atrophied prostatic tissue, while as a matter of fact they belong to an entirely different group

Alexander Randall[24] of Philadelphia, in a recent exhaustive study of the literature on this subject, has collected the various prevailing views of the pathology of this region, and I shall quote from his article extensively

> The German urologists, since the writings of Englisch in 1901, have firmly sustained the view that in the majority of cases the primary change consisted of an atrophic shrinkage of the prostate *gland* and that the obstruction to the vesical orifice was due to a secondary *distortion* from such changes, plus a concomitant sclerosis of the internal sphincter (Englisch Barth, Groslick Datyner, Kummell Posner, Steiner, Burckhardt Caesar, Dubs et al) This conception they have been able to prove by their investigations and then have shown, as first pointed out by Civiale, that when true bar *formations* exist at the orifice, there is at the same time a diminution in the size of the prostate The valve formation of *the older* writers consisting of a simple fold of mucous *membrane,* is not of this type nor is it of frequent occurrence Likewise *small* middle lobe obstruction due to localized glandular hypertrophy forms another type apart from the bar formation due to prostatic atrophy, though with similar obstructive symptoms
>
> *In* 1913, the first comprehensive study of *the actual obstructive* tissue at the orifice was published by Young, comprising the conclusions drawn from over 100 cases in which he had excised the obstruction by *means of* a special instrument, and subjected the tissue removed to a microscopic study This work is of immense value, not only as being the sole investigation of so large a group of cases, but especially because it embraces the study of the actual obstructive tissue as it occurs at the vesical orifice Since the publication of this work covering such a large group of cases, the previous obscure field of the pathologic histology of this condition, aside from its cause, has become more clear That the cases did not fall into one category was to be expected from the previous work on this subject

"Prostatic bar" is not a good name for the obstructive tumors at the vesical orifice It seems to me much better to refer to the condition by using a term more in keeping with the anatomic lesion present In the cases that I have studied, eighty-eight in number, I have found sixty-eight, or 77 per cent, due to a hypertrophy of the subcervical *group of tubules* Ten, or 12 5 per cent, were due to changes *in* the musculature of the apex of the trigonum vesicae Four, or 4 5 per cent, tumors of the subtrigonal group were found Three, or 3 5 per cent, were cases of fibrous stricture of the vesical orifice accompanied by atrophy of the subcervical tubules Two, or 2 5 per cent, were cysts of the vesical orifice, causing marked obstruction Only one case of true middle lobe enlargement has come to my attention Its development is so extensive that it envelops the vesical sphincter and a medium sized hypertrophy of the subcervical group which is entirely embedded in it This specimen bears out the suggestion made to me some time ago by H W Plaggemeyer of Detroit, who is of the opinion that a true middle lobe enlargement does not project through the sphincter, but when that portion of the gland enlarges alone it lifts the sphincter up as well as the apex of the trigonum It has been my experience that an enlargement of the subcervical group of tubules is frequently accompanied by an enlargement of the prostate gland itself, and adenomatous enlargement of the prostate is in nearly every instance accompanied by hypertrophy of the subcervical group of tubules Therefore it is assumed that the stimulating influence which causes prostatic adenoma also affects the subcervical group in a similar manner, with the exception that it causes an earlier reaction in the case of the subcervical tubules

I do not agree with the German view that tumors in this region are always accompanied by a small fibrotic prostate Chronic inflammatory reaction does, of course, occur in many of the prostates associated with an enlargement of the subcervical group of tubules, but there are no specimens in my series which show atrophy of the prostatic tissue combined with this lesion

CONCLUSIONS

1 Obstructive tumors at the vesical orifice, exclusive of adenomatous *hypertrophy* of the prostate proper, are due in my series in sixty-eight, or *77* per cent, of the cases to a hypertrophy of the subcervical group of tubules, and in ten, or 12 5 *per cent*, of the cases to a hypertrophic change of the musculature of the trigonum vesicae as it passes through the vesical orifice

---

[24] Randall Alexander *Prostatisme sans prostate* New York Med Jour., Dec 4 11 1915

to join with that of the urethra In 4 5 per cent of the cases, tumors arising from the subtrigonal group are present, 3 5 per cent of the cases show a fibrous stricture of the vesical orifice, 2 5 per cent have cystic conditions which cause obstruction, there is only one case in this series which shows a true middle lobe enlargement

2 The same stimulation which causes an adenomatous hypertrophy of the prostate in most cases causes an overgrowth of the subcervical tubules, and on account of the greater frequency of the occurrence of the latter condition it is assumed that the subcervical tubules respond to the stimulation more promptly than does the prostate itself

3 The prostate proper is only atrophied when the obstructive mass is due to a fibrosis of the vesical orifice The subcervical tubules are also atrophied in such a case and are found to be surmounted by many layers of fibrous tissue and to be infiltrated with many small round cells

4 Any obstruction at the vesical orifice which causes even a slight retention of urine should be treated promptly in order to relieve a condition which might become serious

5 The treatment should consist of dilatation with sounds, massage and instillations in cases of slight degree In marked cases with considerable residual urine the operation of choice is Young's punch operation Chetwood's galvanocautery and the high frequency current may be used in certain selected cases

6 It is never necessary or desirable to subject the patient to a suprapubic cystotomy for the relief of a tumor at the vesical orifice unless it is accompanied by a general adenomatous hypertrophy of the prostate gland[25]

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS CECIL AND LOWSLEY

Dr H W Plaggemeyer, Detroit Some years ago Dr Keyes stated that it is not the size of the obstruction but its position in the urethra and mouth of the bladder that causes subsequent trouble from back pressure The fact that Dr Lowsley has found that in 77 per cent of these cases there is an enlargement of the glands of Albarran and only one definite median lobe enlargement is to me rather astounding. My attention was first called to this some years ago when helping Dr Young do the perineal operation After a number of recurrences Dr Young began to look for some trouble at the mouth of the bladder and in the floor because that is the anatomic position in which an obstruction is most natural and most easy, except possibly in the circular constriction of carcinoma, and in many of the cases he found this little knob about the size of a hazelnut, which was definitely enclosed in its own capsule It lies in an anatomic plane separate and distinct from the prostate, and in the suprapubic operation it is usually removed In the perineal operation one should always look for this definite little knob, very often small in size, but which may subsequently cause tremendous impairment of kidney function by back pressure I cannot exactly subscribe to the idea of the punch operation in this type of case from a purely theoretical standpoint or from the very nature of the pictures Dr Lowsley has shown this morning, because if this is a definite hyperplasia and we used the punch we would subsequently run the danger of having the aftereffects which we did in former cases in what was then supposed to be middle lobe hyperplasia But the fact that Dr Lowsley has only found one definite middle lobe enlargement might change our whole view of the subject I think that this condition which exists here in young men is the condition that we have been looking for so long, what was previously termed inflammation of the bladder In regard to the high frequency current treatment, it would seem that a preliminary treatment with the high frequency, even to the point of fibrosis, might pave the way for the complete operation by the punch As far as the temporizing operation is concerned, I do not see much to be gained, because with a definite pathologic condition we would only be putting off the evil day

Dr. H J Scherck, St Louis Some time ago I reported a case and I have since then observed a number of cases of superimposed edema at the vesical neck as a cause of vesical obstruction This edema may be like a very large tumor mass In one case the edema was marked when we opened the bladder but we could feel it disappear during the progress of the operation It was superimposed on a hypertrophy of the prostate Since that time I have observed the cystoscopic pictures in these cases of vesical retention without enlargement While there are many causes for it, an important cause I think is unrecognized spinal conditions They are very common, but the type I especially want to call attention to is this edema This edema of the vesical neck, even involving the prostatic urethra, when the pressure is from behind, is a distinct entity In two cases where I could not discover any cause except that for retention I have through the operating cystoscope simply divided the vesical neck two or three times with a little knife just sufficiently to deplete it to some extent, and the retention disappeared for a number of days, until the wound healed, and then the edema appeared again This condition may be so slight as to be hardly observable I believe that in many cases the punch or the cautery operation has the effect of depleting the parts which serve the purpose of relieving the obstruction If the operation is sufficient to leave a groove the effect is permanent In one case the condition recurred again I believe that edema of the vesical neck as a result of an inflammatory condition of the verumontanum, or as an incident in a general arteriosclerosis or a nephritis, may be a cause

Dr Leland Boogher, St Louis It falls to the lot of all of us to drain the urine in these cases, and it depends on how we can best serve the patient in the drainage A few years ago I read a paper on malarial hematuria, and I was severely criticized because I had drained a bladder of 2,500 c c at one sitting I have lately had several cases, and one that far surpassed that Of course, this drainage was done under observation, the patient being in the care of a nurse or a physician all the time The advantage of this drainage at one time, doing it very slowly and only allowing a very fine needle-stream to flow, is that you will regain the muscular activity of the bladder About a month ago a man entered my office to get relief from an acute retention I examined him, and found he had a watermelon abdomen He was suffering acutely Because of the immense dilatation of the bladder an instrument was easily passed at that time, and was left in situ from 11 30 to 5 30 in the afternoon At that time 3,200 c c had passed from that bladder The man had not been able to urinate and had been using a catheter for four months That night he passed 1,000 c c He has not used a catheter since, and the musculature of the bladder has come back into play You can drain a little bit at a time and you can so weaken the bladder that it will lose its muscular activity But if it is done slowly at one sitting, there is 75 per cent chance of regaining the muscular activity and of overcoming the irritation around the prostatic orifice

Dr A J Crowell, Charlotte, N C I have during the last two or three years had a number of cases of retention of urine in young men that I think undoubtedly was due to enlarged verumontanum At least, the treatment for hypertrophied verumontanum did away with the retention We should keep this in mind in thinking of obstructions at the vesical neck in young men

Dr Paul M Pilcher, Brooklyn We must not draw conclusions as to the pathologic anatomy in these cases from specimens removed postmortem in cases in which there has not been urinary obstruction The surgical pathology existing in the cases in which we have actual obstruction is different from that in which we find anomalies or deformities at the vesical neck in which we do not have obstruction I believe our conclusions should only be drawn from those specimens removed from patients where actual obstruction took place I also feel that we may be overenthusiastic in considering these subcervical and subtrigonal glands as the cause of the obstruction in so many of these cases I feel that there is a close relationship between the tubules described as the subtrigonal and subcervical and the actual tubules which form the various lobules of the prostate I believe there must be some error in concluding that the middle lobe obstruction is so rare I have been a great admirer of Dr Lowsley's work and have followed it very closely and am not criticizing it, but I want to be convinced more fully, and I do not think we are yet in a position to pass final judgment

Dr Edward L Keyes, Jr New York Dr Lowsley has studied the anatomic and pathologic prostrate for many years, and I am glad to testify to the accuracy of his pathologic findings Dr Pilcher will find in the literature several descriptions of the glands of Albarran concurring with Dr Lowsley's I venture however, to call Dr Lowsley's attention to the fact that the Chetwood operation can and has been done by me under local anesthesia Removing the small prostate, notably the small fibrous prostate, is the most difficult surgical problem of prostatectomy The solution of that problem I am coming more and more to think is not the high frequency current or the Young punch or the Chetwood operation, or any other of these devices whereby the obstruction is more or less fully relieved We shave the tip off the prostatic enlargement, with relief for a while, then relapse Having done about fifty Chetwood operations I made a report of twenty-five followed more than a year The mortality was very low In the main the results were good At that time—three or four years ago—I reported a certain number of recurrences Last week I operated on two more patients with recurrences If during a suprapubic operation you put your finger in and feel nothing but a tightly grasping contracture, put your finger through that contracture and remove the little intra-urethral sclerotic lobes

Reflex retention in the male is what the French have called 'prostatisme sans prostate," that is retention of urine without notable prostatic enlargement as felt by rectum The causes may be thus classified First, small carcinomas These may usually be diagnosed by rectal examination on a sound in the urethra Second, tabes, diagnosed by spinal fluid, suggested by absence of the ankle jerk Third, the small hypertrophy which gives a normal prostate as felt by rectum, and is diagnosed by cystoscopy Fourth, diverticula, which also are diagnosed by cystoscopy Fifth, the true reflex A few months ago the general service in Bellevue sent down a case with retention of urine They had pronounced the rectum normal, but we found a linear stricture of the rectum This man had several ounces of residual urine, an inflammation of the bladder and frequent urination We anesthetized him, split his stricture and cured him We had a second patient whose inflamed bladder and retention of urine were due to fissure in ano Operating on his fissure relieved all his urinary symptoms

Dr Arthur B Cecil, Los Angeles When I took up the subject of reflex retention of urine I realized that as a clinical entity chronic reflex retention of urine would be doubted It is true that the large majority of retentions of urine are mechanical in origin, due to obstruction in the urethra or at the neck of the bladder If they are not of mechanical origin we have to consider and keep in mind the great difficulty of diagnosing certain obscure nerve lesions In any questionable case a Wassermann test of the spinal fluid should certainly be made In the cases I reported it is evident that the woman from whom was removed the hydronephrotic kidney and who was cured of her bladder disturbances was suffering from a chronic reflex retention of urine It is also true that the case of marked seminal vesiculitis was cured by massage of the seminal vesicles I might say that this man had previously been operated on suprapubically without relief Chronic reflex retention of urine is not a common condition but it is undoubtedly occasionally responsible for some of the cases of inability to empty the bladder

Dr Oswald S Lowsley, New York I am really very glad to get Dr Pilcher's suggestion and Dr Plaggemeyer's suggestion that we go slow in blaming the subcervical group tubule enlargement for so many things I suppose we are inclined to get overenthusiastic about any proposition that we work on a long time I have dissected so many of these cases and have worked on them so hard that I think I am pretty nearly right about my observations concerning the middle lobe There are surprisingly few middle lobes which project into the region of the neck of the bladder When there is hypertrophy of the lateral lobes, there is always hypertrophy of the middle lobe as well, but it is just a connection between the two Anatomically it seems almost impossible for it to project into the bladder in the usual way because the so called middle lobe which I believe is Albarran's group projecting into the bladder, is within the sphincter The middle lobe cannot, I think, project into the sphincter, because it occurs behind the sphincter It does not go back, turn a corner and go into the sphincter This one enormous specimen sticks right out, and there is no doubt about that, but practically all of these specimens removed at operation—I have studied a very great many of them—usually have more or less the appearance of that specimen which I passed around showing the subcervical group separated from everything else by the sphincter and attached to the upper end of the verumontanum and the middle lobe adjoining, with the two lateral lobes, to form the adenomatous hypertrophy Dr Keyes' point was well made about not shaving the tip off of this little nubbin that sticks out Of course, you do not do that because the whole mass projects directly within the vesical orifice, and in doing the punch operation you take out everything that projects and there is not much left to grow out, because you take away the whole mass but I always tell my older patients who have not had a prostatectomy performed that they may have to have it later on Even if it is only palliative, it gives them good drainage It has the same effect as wearing an indwelling catheter Then if the prostate becomes obstructive, as it is liable to do in these old men, you have already promised him that he might have to have a more serious operation later on, but, in the meantime, this palliative procedure is still worth while in my opinion In the younger men the men around 30 and 40, you do not have to consider that point, because as a rule, the enlargement of the prostate is not considerable

Edema at the vesical orifice is quite prevalent The thing to do is to find the cause of the edema and relieve it, but in finding the cause it is possible to get a temporary relief, in which case some form of cauterization is better, either silver nitrate or the high frequency current or some such procedure I am very glad to know that Dr Chetwood's operation can be performed successfully under local anesthesia In cases of fibrous stricture of the vesical orifice that is the operation that should always be performed if it can be done under local anesthesia The results are always good

---

THE OPERATIVE TREATMENT OF TUBERCULOSIS OF THE SPINE*

NATHANIEL ALLISON MD
AND
HERBERT H HAGAN, MD
ST LOUIS

This report is made in order to give our experience with forty cases of tuberculosis of the spine in which operation has been performed in a manner designed to stiffen their spinal columns by internal splintage Two methods of operation have been used the osteoplastic operation, known as the Hibbs operation, and the bone transplant operation, known as the Albee operation

Of the forty patients operated on, nine had reached adult life before the onset of the disease, and thirty-one were children The oldest patient was 37 years of age and the youngest 19 months of age The diagnosis of tuberculosis of the spine was made positive in each case by roentgenographic study, the exact location and extent of the disease being clearly made out, and by clinical tests for tuberculosis, and, wherever possible, by guinea-pig inoculation

Our first operation was done Oct 5, 1912 Six patients were operated on in 1913, eleven patients in 1914, fourteen patients in 1915 and nine patients of this group in 1916 Of these forty patients, ten were operated on by the method of Hibbs and thirty by the method of Albee

We have divided the cases into three groups in order more briefly to present their clinical characteristics

Group 1 Patients operated on in the early stages of Pott's disease with little or no evidence of deformity and no complications

Under this head fifteen of our forty cases fall Without exception, this group of fifteen patients have stood the operation well, have had rapid convalescence, all symptoms have disappeared, and we feel that they represent complete recovery

Group 2 Patients operated on that presented well marked deformity with persistence of more or less acute symptoms, but no complications

Under this head nine of our forty patients are collected Of these nine, eight have made recovery and are about without supports and are in fairly robust health One patient has shown a return of acute symptoms after three years, and has signs of a developing pressure paralysis

This patient was operated on after the method of Hibbs and did very well up to three months ago She is now being treated as one would treat conservatively a case of Pott's disease with paraplegia

Group 3 Patients who were operated on in the presence of complications to their more or less acute processes of tuberculosis of the spine

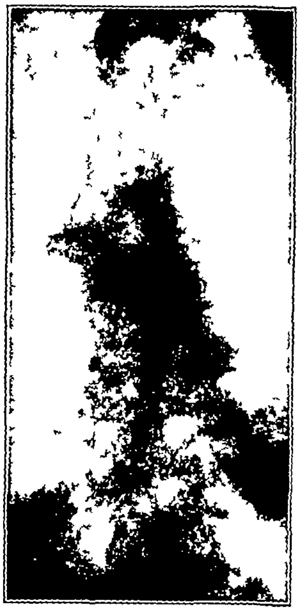

Fig 1 — Roentgenogram of bone graft taken one year after operation showing fracture of graft at seat of disease

These complications were psoas or lumbar abscess, 5 cases, tuberculosis of other joints, 2 cases, pressure paralysis, 5 cases, pregnancy, 1 case, pulmonary tuberculosis, 4 cases

Psoas or Lumbar Abscess—Of the five cases that presented abscess formation as a complication to the Pott's disease, three were treated conservatively as far as the Pott's disease was concerned, and the abscess was opened, its contents cleaned out, and the wound closed In these three cases we had primary union of the incision for the cleaning out of the abscess

The operation on the spine was then undertaken In one of these cases the abscess refilled and discharged through the line of incision In the other two cases the abscess did not refill

These three abscesses were psoas abscesses

In two of the cases, abscesses occurred after the operation on the spine, and they were treated in a similar manner In one case we obtained healing, and in the second case the abscess continued to discharge but finally closed

We are led to believe from this experience that abscess formation is not a contraindication to the operation on the spine

Tuberculosis of Other Joints—In two of our cases, in addition to having Pott's disease the patients had also tuberculosis of the hip joint After the subsidence of acute symptoms the spine was operated on, and the hip has been treated conservatively in the ordinary manner One case has been treated with a jacket spica and the other with a Bradford abduction hip splint Neither of these patients has shown any retardation in their convalescence since the operation

---

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

Paraplegia—Five of our patients have shown symptoms of spinal pressure evidenced by increased reflexes, ankle clonus, and inability to walk or stand

One of these patients, a man of 30, had symptoms of Pott's disease for five years with a gradually increasing deformity About two years ago he noticed a jerking of his legs when bearing heavy weight on his toes, shortly after this his legs became weak, especially the right one, and now the toes drag on the floor when walking, and his gait is very stiff The physical examination showed a sharp line of hyperesthesia extending across the trunk at the level of the sixth dorsal on the right and the fifth dorsal on the left Below this there was definite hypalgesia On this man an Albee operation was done, Sept 16, 1914 After the operation his area of hypalgesia gradually lessened and entirely disappeared, his ankle clonus, spasticity, and plus reflexes have now disappeared, and he is about without symptoms

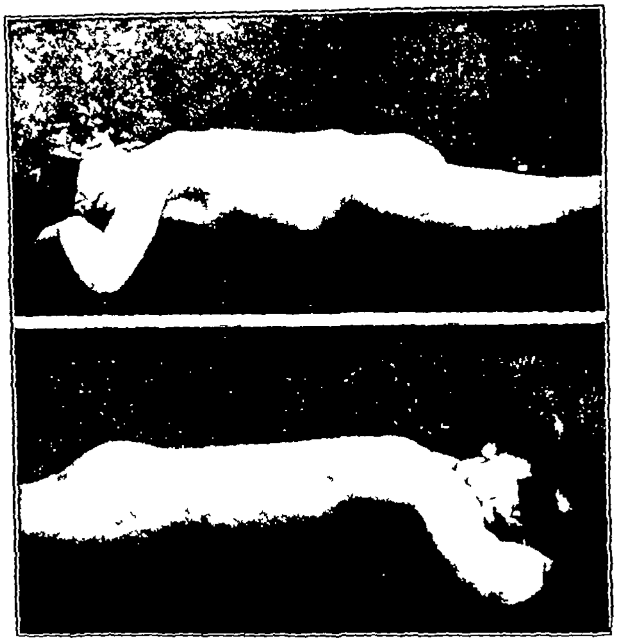

Fig 2—Lessening of deformity after Albee operation

The second patient, 2 years of age, Jan 27, 1915, showed clonus on both sides, Babinski on both sides, and very active knee jerks and no voluntary power of the thigh or legs He was operated on, March 22, 1915, an Albee operation being done from the seventh cervical to the tenth dorsal, being secured by a tibial graft April 5 1915, voluntary power had returned to some extent, in both legs, Babinski was *still* present, and clonus still present. April 28, the child began running a temperature with no assignable cause May 19, patient is able to move his legs very well Babinski has disappeared and also clonus June 26 after a gradual onset the child died of tuberculous meningitis One other child in this group who had complete paraplegia died three weeks after the operation of tuberculous meningitis

The two remaining cases of this group had only slight involvements evidenced by ankle clonus slight spasticity and positive Babinski These two patients after operation rapidly improved The signs of spinal pressure disappeared, and they are now about without symptoms

We have been led to conclude from our experience with paraplegia as a complication in Pott's disease that an operation should immediately be done, as it seems to us to offer the best chance for a speedy recovery from the pressure on the spinal cord

The two patients in this group who died died of tuberculous meningitis, and we have no explanation to offer for the occurrence of this fatal complication

Pregnancy—One of our patients, a woman of 19, had just recovered from her first pregnancy when she began to notice the symptoms of Pott's disease

She had a well marked and rapid destruction of her first lumbar vertebra, and appeared at the hospital with her five months old infant The infant was weaned and the mother was operated on several weeks later, a perfect result being obtained She gained weight and was about without symptoms at the end of ten weeks and was discharged to her home In spite of our advice she returned to the hospital at the end of six months again in a state of pregnancy This pregnancy was allowed to run full term and a normal infant was born The mother made a normal recovery, and since then has had no symptoms of activity in her diseased spine A roentgenogram of her graft illustrates this report This was taken after her second pregnancy and shows the graft in good position but broken through its middle

In passing, it has been our experience in the study of these grafts after they have been placed in the spine that some of them show signs of fracture after a more or less indefinite period without causing any evidence of trouble

Pulmonary Tuberculosis—In our group of forty cases we have had four cases that showed signs of more or less active pulmonary involvement In spite of this complication we have done the operation, doing it as rapidly as possible, so as to cut down the length of time required for the administration of the anesthetic It has been our custom in these cases, and we might add in all cases where the physical condition of the patient was below par, to prepare the patient completely for operation and have everything ready to go ahead before the anesthetic is administered As soon as the patient passes the primary stage of anesthesia, the operation is then started and finished as rapidly as possible In this way considerable time has been saved In none of these four cases has there been any evidence of the operation causing increased activity in the pulmonary involvement

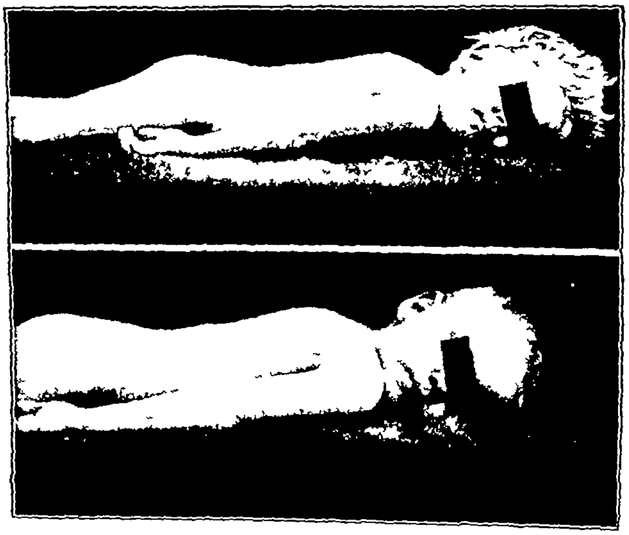

Fig 3—Lessening of deformity and rapid improvement in general condition after Albee operation

Complications from the Operative Procedure—In three of the forty patients operated on there has been infection at the time of operation of the operative wound

One of these patients, a man of 27, developed a severe *Staphylococcus aureus* infection on the third day after operation in both the wound on the shin and in the back After a very serious illness from this infection he gradually recovered and his wounds closed Two pieces of his graft were discharged, one from the upper end of the wound and one from the lower Healing finally took place and his result has been an excellent one

The other two cases were slight infections, one of them involving the lower end of the graft, which was discharged, the other being simply a superficial infection at the site of the skin sutures The other thirty-seven operated cases healed by primary union

We have been struck in this series of cases, especially in children, with the immediate improvement in general health and with the rapid convalescence that these patients have made after operation Almost without exception, the children have gained weight, have become very active when allowed to be up, and presented a marked contrast to the slow improvement seen in cases treated conservatively

We discovered, what seems to us, to be a valuable method of holding these cases fixed immediately after operation It is our custom to reverse the Whitman frame so that it lies concave on the bed, and place the child, face down, on this frame, securely binding it as one would in the reverse position In this way there is no pressure on the operative wound, and the position of hyperextension is more or less perfectly kept up

We feel from our experience that it is highly advisable, and, indeed, in certain cases necessary to continue support for at least one year after the time of operation We are led to this belief by the character of bone regeneration which must take place before the spinal column becomes securely ankylosed, and we feel that the too early removal of supports is likely to result in a return of symptoms and an increase in deformity

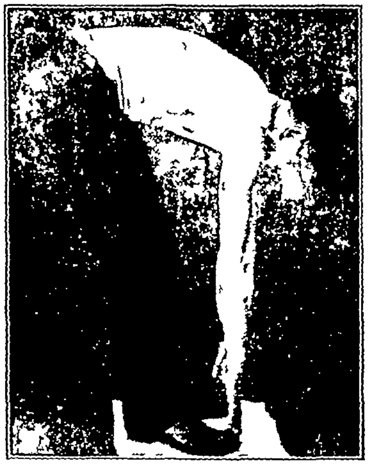

Fig 4 —Ability to flex the spine one year after Albee operation

SUMMARY

Forty patients were operated on

Two deaths were due to tuberculous meningitis

There were three infections at the time of operation without serious consequences

Fifteen patients completely recovered without deformity or complication, and at the present time are far enough along since their operation to be called absolutely well

Eight patients have deformity, but with the disease arrested and no active symptoms

Of the sixteen patients who had complications three with paraplegia have completely recovered, and two have died

Of those with pulmonary tuberculosis (four patients) there is evidence of activity of disease at present, but the disease of the spine is not causing symptoms

Of the patients with tuberculosis of other joints (two) these are still under treatment, but are making slower recoveries

Of the patients with psoas abscess (five) all five have recovered and the abscesses have ceased to discharge

The total of this group would be four cases of pulmonary tuberculosis, and two of tuberculosis of other joints, making six still under observation, leaving ten in which the disease has been arrested

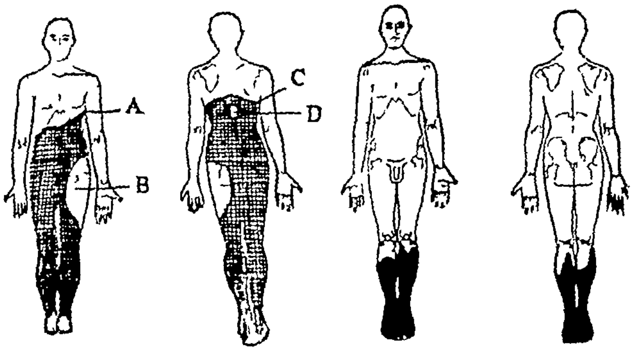

Fig 5 —Rapid improvement in sensory changes in a case of paraplegia after Albee operation three weeks time patient made complete recovery shaded area, hypalgesia *A*, narrow zone to hyperalgesia *B* area of normal to increased response to pin prick *C* hyperalgetic zone *D* gibbous

We are led to believe from this experience with forty cases that an operation for ankylosing the spine should be performed in every case of Pott's disease as early as a diagnosis can be accurately made, and that the presence of complications should not influence the surgeon in delaying the operative procedure, unless the complications are of too grave a nature

We do not feel in a position to discuss the relative merits of the Albee operation and the Hibbs operation We have had equally good results with each procedure We feel, however, that the Albee operation is more simply done and that on this account it is advisable in the majority of instances

Our experience with adults and children has been about the same We feel, however, that the good results obtained are much more conclusive in the case of adults, who respond very slowly to conservative measures

537 North Grand Avenue—600 South Kingshighway

ABSTRACT OF DISCUSSION

Dr J T Rugh, Philadelphia I want to endorse all that Dr Allison said regarding the after-treatment of these patients He has shown clearly the unwisdom of leaving off the support too early in these cases, especially in young children Support must be maintained until bony union takes place, which requires six months to a year or a year and a half I operated in one of these cases by the Albee method, a case of tuberculosis of the atlas and axis The child was struck on the side of the neck with a baseball bat About four hours

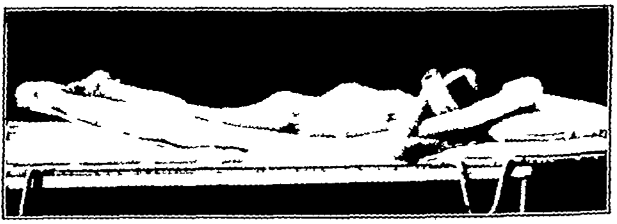

Fig 6 —Reversed Whitman frame used for fixation after operation

later he dropped in the street paralyzed It was thought that the paralysis had come from the injury, but the subsequent history showed that he evidently had a tuberculous lesion there and that this accident had simply precipitated the entire trouble He remained paralyzed for four or five weeks, when an abscess ruptured on the side of his neck and discharged, after which the paralysis cleared up He came under my care a year and a half after the onset of the tuberculous trouble, with slight spasticity in the lower extremities I dug a hole in the occiput, and measured my graft to fit between it and in contact with the third and fourth cervical spines I placed the end of the graft in the lower pocket, tilted the head forward, and inserted the graft into the hole in the occiput Then I tilted the head back and sewed the graft into place There were no complications, and he made a splendid recovery The paralysis has entirely disappeared Before I operated, if his head tilted forward, he would immediately become paralyzed, and it had to be held back from six to eight hours before the paralysis disappeared Since the operation, there has not been this trouble

Dr James T Watkins, San Francisco I want to show you pictures of the spine of a child who died several months after I had performed a Hibbs operation The morbid process involved the bodies of two vertebrae in the middorsal region, and at our operation we synostosed the laminae of six vertebrae, going well above and below the lesion Dr Ely said that his sections showed that the spines had disappeared By that I suppose he meant that they had lost their configuration as spines and had become fused with the laminae One can still differentiate them in the picture

NEW METHODS OF PRECISION IN THE TREATMENT OF FRACTURES *

GEORGE W HAWLEY, M D
BRIDGEPORT, CONN

The treatment of fractures is largely a mechanical problem, and in spite of the fact that this is a mechanical age, little progress has been made in the mechanics of fracture treatment In fact, the assertion has been made that many of the methods and devices in use today might easily be mistaken for implements belonging to the era of the wooden plow Even the method of applying weights to fractures of the femur, as popularized by Gordon Buck as recently as fifty years ago, would have a familiar look to some of the ancients

It is true, of course, that advance has taken place in the care of fractures, but the advance has largely been incidental to the development of roentgenography, and in the direction of technical and instrumental improvements in the operative treatment of fractures

The simple methods have not received the attention which is their due, and even in the operative methods, the development has been in the direction of applied mechanics One thing Lane emphatically demonstrated is the fact that successful fracture operations are impossible without efficient instruments and without a technical dexterity in the handling of exposed tissues hitherto unknown

It is strange in this age of automatic machinery and instruments of precision to see so much dependence placed on the manual treatment of fractures It is strange because hands must vary considerably in strength, skill and performance The tradition "hand made" has lost much of its glamor There would be no such things as automobiles, aeroplanes or submarines if their parts had to be turned out by hand When it comes to precision and uniformity, mechanical methods must supersede the manual in the treatment of fractures, as in any other work in which the intelligent application of force is required Any one who has attempted to exert traction on a broken limb and to hold it in a fixed position appreciates that it is not as simple as it looks Even skilled hands become unsteady and fatigued The element of unreliability is always present and increases with the inexperience of those who assist in the undertaking

The time was when the diagnosis of fractures was made without the mechanical aid of the Roentgen machine, and the time is fast approaching when the treatment will not be undertaken without methods and apparatus of precision It is impossible to apply force accurately by methods which are necessarily inaccurate The opportunity for improvement in the simple methods of fracture treatment is abundant, and as these simple methods are made more efficient the necessity for open reduction will diminish

The time is not far off when fractures will be almost entirely treated in hospitals In fact, it will be difficult, as well as dangerous, to attempt to do so, because the public will be aware that complete scientific equipment for diagnosis and treatment can be found only in such institutions There are few communities in which people are not within reach of a fairly modern hospital Here they can be efficiently and promptly treated and sent home to convalesce In this way, fracture patients become no burden to a hospital

At the same time it will be necessary for the hospitals to devote more attention to the care of fracture cases The public is becoming educated, and it is a public accustomed to "modern improvements" Moreover, the industrial world, which pays the disability bills in occupational fractures, is becoming interested Not only must the apparatus be efficient, but its use must be in the hands of men especially trained for the work It will no longer do to divide the fracture cases into small lots and assign them to men whose chief qualifications are that they are interested and proficient in abdominal surgery

With the introduction of more precise methods, the treatment of fracture cases will become more systematic Much of the unnecessary handling of broken limbs will be eliminated This will save a vast amount of needless suffering and promote the processes of repair One of the noticeable features will be the dispatch with which these cases will be handled

There is no reason why a fracture patient entering a hospital should not be placed on a bed and a spli[illegible] applied which permits physical and roentgenograp[illegible] examination without disturbing the limb in an[illegible] There is no reason why roentgenograms should [illegible] taken at once, so that when the attending [illegible] arrives, the complete record is before him [illegible] permanent treatment can be instituted with[illegible] This simulates the treatment of surgical [illegible] (osteotomies) in which almost no difficul[illegible] enced, because the bones are appro[illegible] immobilized before the muscular co[illegible] become fixed

In the treatment of some 3,000 cases [illegible] during the last seven years, I have prac[illegible] ticed the immediate reduction and [illegible] fractures under ether During this [illegible]

cut or split a cast in anticipation or on account of swelling. In fact, the only cases of extensive swelling or of bleb formation (so commonly associated with fracture) which I have seen are those in which the treatment was delayed. As I have successfully proved to myself that the mortality and suffering in fracture of the hip in old people is directly due to conservative treatment, so I believe that if we are looking for swelling and trouble, then treat fractures expectantly. If we wait until the swelling disappears, it is only necessary to wait for it will not disappoint us.

THE TREATMENT OF FRACTURES OF THE FEMUR *

F. E. PECKHAM, M.D.
PROVIDENCE, R. I.

1. THE MIDDLE THIRD

Fractures of the femur in the middle third have aroused considerable discussion in recent times regarding methods of treatment. Different mechanical methods have been advocated by different surgeons, and finally the open method with the use of Lane plates occupied the center of the stage and caused quite a little excitement.

A fracture is a definite mechanical problem. First of all, a roentgenogram is necessary to see exactly what the condition is, whether transverse, oblique or comminuted. How far the fragments are riding by is also a good thing to know. In these fractures, the result is so easily obtained that, in the great majority of cases, no anesthesia is necessary, and there is no "setting of the bone" in the ordinary acceptation of that expression. Every orthopedic man learned during his early hospital training that an acute tuberculosis of the hip with its muscular rigidity and flexion deformity was overcome by traction. Pain was relieved almost instantly and muscular contraction was overcome by constant, incessant and efficient traction.

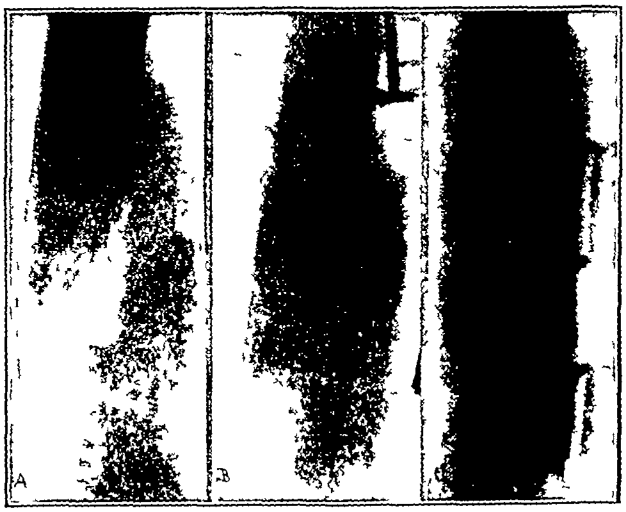

Fig. 1 (Case 1).—Oblique fracture of femur: *A*, fragments pulled down to length; *B*, *C*, result of gradually tightening the coaptation splints.

In a fracture of the middle third of the femur, traction properly and efficiently applied will just as surely overcome the muscular contraction which is the cause of the fragments riding by, thus producing shortening. For traction to be efficiently applied in this particular condition, countertraction must be equally efficient. Here is where the treatment, as usually prescribed in textbooks, fails. Efficient countertraction or counterextension is considered to be accomplished by elevating the foot of the bed. Nothing could be further from the truth. Elevation of the bed is usually (although not always) necessary, but to get really efficient counterextension, a well padded perineal band is placed in the groin, one of the straps going over the front of the body, the other going beneath the body, with a pulley at the head of the bed. Weights are then added to both the foot and the head of the bed, varying according to the necessities in the individual case. In the direct extension, anywhere from 10 to 40 pounds may be necessary. The foot of the bed may be elevated as usual and then about one-half the weight necessary in the direct extension may be added for the counterextension. If 30 or 40 pounds are necessary for the extension, then use 15 pounds for the counterextension. This makes a traction in each direction, thus pulling the fragments apart in the longitudinal direction of the leg.

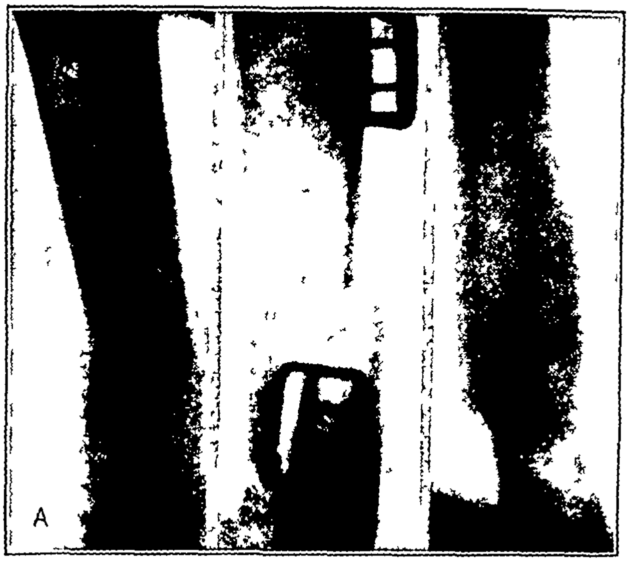

Fig. 2 (Case 2).—Oblique fracture of femur: *A*, fragments pulled too far apart by over an inch; *B*, apposition obtained by lessening the weight; *C*, condition a little less than a year after the injury.

If this "two way" pull is kept up constantly, incessantly and efficiently, there is usually only one thing can happen, and that is the fragments will be pulled down so that, in the middle third, they will almost fall into apposition. Coaptation splints may be placed about the leg, but they do not need to be really adjusted and tightened until the leg is down to length. Now and then, a strand of tissue may be caught in such a way as to hold one end from just going into position. Under such conditions, pressure and counterpressure by pads of sheet cotton beneath the coaptation splints will usually correct. In case there should be a large piece of muscle interposed to prevent apposition, then all that is necessary is to take the patient to the operating room, bed and all, without removing the extension weights. After the usual preparation, make the incision, expose the fragments, remove the obstruction, and the ends will either fall into apposition or can be easily held by the coaptation splints over a light surgical dressing

---

* Read before the Section on Orthopedic Surgery at the Sixty-Seventh Annual Session of the American Medical Association, Detroit, June, 1916.

* Because of lack of space this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

This method would seem to reduce the treatment of fractures in this location to their very simplest terms, and I wish to report some cases treated in this manner

Case 1—Mr A An oblique fracture of the femur with about 2 inches' shortening Extension of about 40 pounds with foot of bed elevated and counterextension of 15 pounds At end of ten days with coaptation splints tightened, the fragments were down and together (Fig 1) Discharged from hospital with no shortening This case was treated about one year ago, and a letter from the man states that he is at work (putting in elevators) and that he walks without a limp

Case 2—Mrs B This was an oblique fracture of the femur with 1½ inches' shortening Extension of 35 pounds with foot of bed elevated, and counterextension of 15 pounds At end of two weeks (Fig 2 *A*) the fragments had been pulled over an inch apart, i e, the leg had been pulled down until it was that much too long Removing 10 pounds from the direct extension, the leg shortened up till the fragments were in apposition, as shown in Figure 2 *B* This was treated a little less than a year ago, and in April, 1916, the patient reported at my office with no shortening, no limp, and the Roentgen ray shows the condition in Figure 2 *C*

Case 3—Boy, aged 4 years Oblique fracture in middle third of femur Extension of 15 pounds with counterextension of 10 pounds easily brought the leg down to length (Fig 3 *A*), but the Roentgen ray showed the fragments "back to back" (Fig 3 *B*) instead of edge to edge Under ether an attempt was made to readjust them, but with *no result* Then the boy was taken to the operating room in his bed, with extension and counterextension in full force (Fig 4) The leg was cleared of adhesive straps from the knee up and prepared for operation in situ An incision was made through the skin, and then the muscle bluntly dissected to the bone, where a piece of muscular tissue was removed from between the fragments The broken ends fell into apposition immediately The skin was sutured and a light surgical dressing applied and boy bed and all returned to the ward Union promptly resulted, with a perfect leg, as shown in Figure 3 *C*

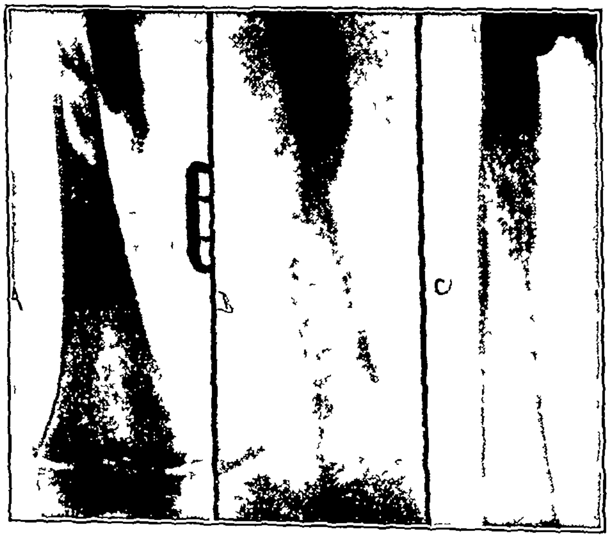

Fig 3 (Case 3)—Oblique fracture in middle third of femur *A* leg pulled down to length *B* fragments back to back instead of in proper apposition *C* union some months afterward

2 FRACTURES OF THE HIP

Appreciating that with extension and counterextension, the leg can hardly help coming down to length, it occurred to me that with proper mechanics, fractures of the hip could be readily treated without the use of the plaster spicas A number of hips at different times having been opened through the anterior incision for the purpose of exploration and freshening of the broken surfaces, it was ascertained in this way ocularly that if the leg was pulled down to length and strongly internally rotated, the broken ends became locked in apposition The getting down to length is easily accomplished by efficient extension and counterextension, as already described The internal rotation is easily accomplished by rotary pulls by means of adhesive plaster straps extending around the leg from the top, over the inside and under the leg, then passing up over a particularly wide T splint In this way the extreme degree of internal rotation may be obtained and held With these mechanics kept perfectly efficient, the fragments are kept locked in apposition as verified by the Roentgen ray

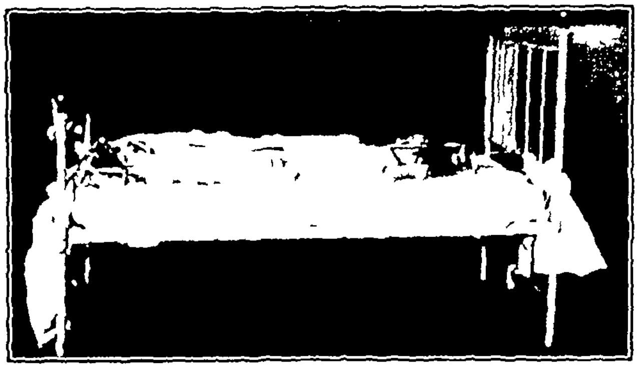

Fig 4—Method of extension and counterextension

I wish to report two cases to demonstrate the efficiency of the mechanics

Case 4—A man sustained a fracture through the great trochanter with shortening of 1¾ inches The leg was pulled down and internally rotated, thus bringing the broken surfaces into accurate apposition The recovery was perfect, with possible flexion

Case 5—A boy sustained a separation of the epiphysis of the right hip, but continued to walk around on it, although lame and painful Three months after the accident, the boy was brought for examination The Roentgen ray showed the condition Efficient extension and counterextension with strong internal rotation brought the hip down into position Union was obtained, however, and scarification of the surfaces became necessary, but the roentgenograms are exhibited to demonstrate the possibilities of the mechanics as described above

The results in these two cases were so encouraging that others have been treated in a similar manner with similar results When treated in this way, the back and whole body is easily reached with alcohol and powder, and the patients are much more comfortable than those I have seen in plaster spicas

266 Benefit Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS HAWLEY AND PECKHAM

Dr Fred H Albee, New York We employ the Hawley table in all cases of fracture in any part of the body where it is difficult to get replacement and hold the fragments firmly in position

Dr J T Rugh, Philadelphia I want to speak of three cases of ununited fracture of the hip, one in a woman past 60 years of age Two of these cases have been entire successes and the third patient is not cured In a case of old fracture of the neck of the femur a graft was placed

That patient, at the end of many months, is walking well, with perfect results A case of twisted fracture was also an excellent result In another case there was some comminution in the head of the bone When the graft was placed it, unfortunately, did not penetrate as far into the innermost piece of the head of the femur as it should It has been a year and a half since the operation, and the patient is not yet walking I could not understand why until I found that the graft did not penetrate all the fragments I think that the secret of success is to get the peg through both or all the fragments Then it does not make any difference whether the peg is round or square If it is through in proper position, the result will be good

Dr John Ridlon, Chicago As to the Hawley leverage device for congenital dislocation of the hip, I would say, in the first place, that it is not necessary to use any leverage device to replace a congenital dislocation of the hip In the second place, it is dangerous to use it, because, with a leverage device like that and the one on the Bartlett apparatus it is possible to fracture the neck of the femur We fractured one with the Bartlett apparatus As to Dr Peckham's fracture work, it is possible to pull down some fractures of the shaft of the femur, and when you have pulled down three or four, you think that you can do this in all cases, but you cannot I have had a case in a man of great muscle development where 58 pounds weight for 8 days did not reduce the displacement at all We have to use traction, in such cases, to an enormous amount to pull the fragments down, and when they have been pulled down they do not always drop into place," and we cannot always manipulate them into place In this case, when the leg was opened and the bones pulled down with a space of half an inch between the ends of the fragments and the traction slowly relaxed, instead of the fragments going end to end, they went just where they were before, and there was no tissue between the ends, muscle or otherwise

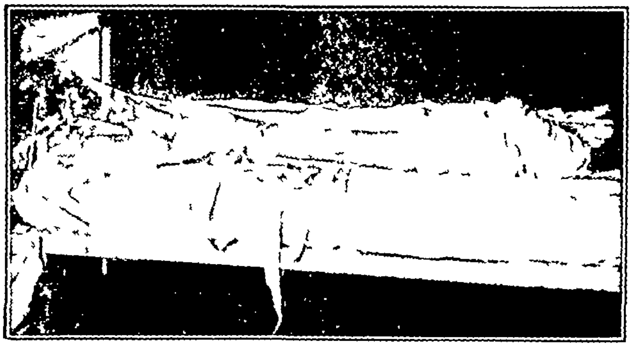

Fig 5—Wound the day the stitches were removed method of operating

Dr. H R Allen, Indianapolis I enjoyed the demonstration of the use of the operating table with all of its fancy attachments and complications and believe it would be very gratifying to a man who feels that the plaster of Paris dressings are essential or scientific Personally, I do not use such dressings for any human condition that I have ever seen I do not like the use of inadjustable splints that conceal the results I prefer splints made of wire and adhesive plaster They are light, cheap, adjustable and sanitary, and permit inspection at all times Such splints do not conceal errors If you choose you can apply the splint before operating then when the operation is through you are through These splints do all that a plaster splint can do and as much more as you desire They are easy to make and easy to apply and they are comfortable and do what is expected of them I agree with Dr Ridlon But Dr Peckham has never found a case that could not be reduced by traction alone Dr Ridlon and I and others have found plenty of this variety Suppose you have a square ended fracture with overriding in a thigh whose ham-strings are tight on simple knee extension, how would you expect the jagged ends of the bone to slip past each other into place? If you unlock the thigh muscles by flexing the knee then the fragments will easily go to place Then, after flexed reduction you lock the broken ends tight together by complete knee extension There is a use for this mechanical tightening of the ham-strings but this use is not absolutely dependable Dr Peckham's method of traction will reduce most of the spinal fractures of the thigh, but what good is reduction by any method unless you follow it up with some guaranteed method of maintaining reduction Really, the maintenance of reduction is all that counts since every bone will unite in the position in which it is held and in no other position

Dr J C A Gerster, New York Dr Howard D Collins has devised a most ingenious and convenient traction bandage-sling for use in connection with Dr Hawley's table Before applying the bandage two pieces of felt ¼ inch thick and 4 inches wide are laid next to the skin One, 6 inches long, is laid in front of the ankle over the dorsum of the tarsus, the other, 4 inches long is laid over the Achilles tendon The bandage is of stout Canton flannel, 3 inches wide and 2 yards long The bandage forms two symmetrical hitches, one in each side of the ankle Each hitch forms a Y, one limb passing in front and one behind the ankle Traction is made by pulling on the stems of the Y's As soon as traction is released, constriction ceases This spontaneous relaxation of the hitches would not take place if they were so applied that they formed T's instead of Y's By appropriate adjustment, varying the site to suit each case, the points where the limbs and stems of the Y's meet can be so placed that the subsequent traction suffices to hold the foot correctly inverted and at right angles to the leg As soon as plaster has set the projecting stems of the Y's, by which traction is maintained, are cut off flush with the cast The blueness of the toes from interference with the venous return, present up to this time, subsides immediately, because constriction ceases on relaxation of traction The advantages of nail extension are many for cases in which, on account of associated trauma to skin, etc or on account of long standing shortening, the customary plaster of paris or traction methods are unsuitable In fractures, properly treated from the very start, nail extension will not be indicated in more than 4 to 5 per cent of the cases

Dr Edwin W Ryerson, Chicago It is perfectly evident that many fractures of the femur can be treated as has been outlined by Dr Peckham, but some cannot, and other treatment must be used Dr Albee said that we need exact doweling to secure union of bone fragments That is desirable without doubt, but I have a perfect case in which I took the bone-spike from the tibia and filed it nearly round with a rasp and file, without using a doweling instrument This was a complete fracture of the neck of the femur, incurred a year previous, a so-called intracapsular fracture Another point I wish to refer to is the use of the motor drill for making holes in the upper end of the femur I do not think you need it I believe that it winds up the soft tissues too much, as Dr Allen said a year or so ago It is better to have the drill point in a plain hand-drill, because the work is then easier and safer, and you can control the drill better in going through the bottom of the trochanter You should not start the drill on the trochanter itself, but just below the trochanter, and go obliquely upward and inward In one of the roentgenograms shown the bone-peg was inserted at a right angle to the shaft of the femur This is not the way I prefer to do I go down under the overhanging border and drill upward and inward, and this is easier with the hand-drill than with the motor-drill I have found the use of the Hawley table very satisfactory I think that it solves many of our problems In a clinic where much fracture work is done, I consider it invaluable

Dr Frank E Peckham, Providence, R I I do not think that any one can succeed every time I selected three pretty bad cases and they resulted very well I think that the less metal we put in the better I would suggest as a good motto, "M M J"—Minimize metallic junk

---

The Partnership of Genius and Labor—Genius begins great works, labor alone finishes them—Joseph Joubert

Therapeutics

TRINITROTOLUENE POISONING

In the ammunition factories of Great Britain, trinitrotoluene, one of the high explosives employed, has been found to be dangerous to the health of a minority of workers coming in contact with it, and has proved fatal from toxic jaundice The matter has become so important that the medical inspector of factories has prepared for the benefit of practitioners a paper on the chemistry of trinitrotoluene (or T N T, as it is designated), its method of absorption, the symptoms produced by it, the precautions to be taken against poisoning, the method of treatment, and the differential diagnosis of trinitrotoluene poisoning from that of dinitrobenzene, tetryl and lyddite, the latter a picric acid derivative[1]

Trinitrotoluene is a high explosive obtained by nitrating toluene, from coal tar, a benzene compound in which one hydrogen atom is replaced by CH_3, and in which during the process of nitrating three other hydrogen atoms are replaced by the nitro radical, NO_2 The product is solid at ordinary temperatures and may be reduced to a fine powder, melts at 80 C, and sublimes when melted

When the skin or hair is exposed to trinitrotoluene by contact, a characteristic yellow or tawny orange stain is produced, which is removable by oils, greases, acetone, ether, benzene and other compounds, but not by water When trinitrotoluene is treated with alcoholic solution of potassium hydroxid, a deep pink color changing to purple and then to brown is produced, and this reaction is employed in testing for trinitrotoluene in urine, after the latter is treated to release the trinitrotoluene from its combinations, a rather complicated procedure

Trinitrotoluene can be absorbed to a dangerous extent by the skin, and as fine dust or as sublimate will reach the mucous membranes of the nose and mouth, or perhaps even the lungs, and may be swallowed with the secretions of the mouth, nose and throat It may be recovered from the feces unchanged in most workers, and in many from the urine, but only in combination Among the symptoms it produces are dermatitis, much like that produced by other irritants, increased by flushing and perspiration and by friction, gastritis, with abdominal pain, vomiting, constipation which is constant, flatulence and distention, and blood changes similar to those of dinitrobenzene poisoning, with the presence of methemoglobin, though cyanosis and breathlessness are less evident Cell degeneration is readily produced by trinitrotoluene, and when the liver is involved toxic jaundice results, though in only a few cases Evidence of gradual absorption is shown by pallor of the face and an ashen gray color of the lips, sometimes the lips and tongue are deeply cyanosed Jaundice may be conjunctival or general, and often appears suddenly during the first four weeks of exposure Liver dulness is variable, ascites is sometimes present, respiratory distress is not noticeable when the patient is in bed, and pyrexia has occasionally been observed in severe cases, but neither bradycardia nor pruritus is common Two deaths from anemia unassociated with jaundice have been reported, with reduction of red cells to one million, of unequal size, but no poikilocytes or nucleated reds Microscopic examination excluded pernicious anemia Death resulted from hemolytic aplastic anemia, the blood-forming marrow having been greatly reduced

Points of differential diagnosis are the characteristic appearance already described, the character and situation of the abdominal pain, and the presence of constipation and abdominal distention It may be confused with other gastric disturbances, and must be distinguished from tetryl and picric acid poisoning, the former staining the skin a yellow or apricot color, the latter a canary yellow or greenish yellow, both set up a dermatitis similar to that of trinitrotoluene, but the constitutional symptoms are not pronounced, and toxic jaundice from them has not been reported

Postmortem, the outstanding feature is atrophy of the liver, which in some cases is reduced to half the normal weight Microscopically, the greater part of the liver tissue is found to have undergone complete destruction, associated with proliferation of fibrous tissue The kidneys are large and icteric, the cortex bulges, the labyrinths are frequently yellow, there is engorgement of the pyramids, and cloudy swelling and fatty degeneration of the tubules

Treatment in the absence of jaundice is simple removal from contact, rest in bed for a day or two, a diet consisting of milk, milk puddings, fruit and green vegetables, demulcent drinks, such as barley water tea and coffee, for the constipation, vegetable laxatives and cascara, with a mixture containing sodium sulphate, potassium citrate and sodium bicarbonate as a routine measure In jaundice cases, absolute rest in bed is essential, milk diet, small in quantity at first, gradually increasing to 4 pints a day, the bowels must be kept loose, preferably by mistura alba (a mixture containing magnesium carbonate, magnesium sulphate and peppermint water) repeatedly given In jaundice with marked toxic symptoms the prognosis is grave Alkali-producing drugs, such as the citrates and bicarbonates, should be given to overcome the tendency to acid intoxication Rectal and intravenous saline injections have a place in the treatment of severe cases

---

DISTURBANCES OF THE KIDNEYS

(*Continued from page 372*)

Nephritis

CLASSIFICATION

Were it possible absolutely to accept Fischer's theory of nephritis, namely, that an overproduction of acid in the body or an accumulation of acid in the kidneys is the usual cause of this condition, many complex problems connected with it would become simple If, as he believes, it were true that the edema is due to too much acid in the system, and that most of the uremic symptoms are due to cerebral edema, our understanding of the pathology and the treatment of these conditions would be clearer, but, unfortunately, the treatment which he sometimes recommends to overcome the supposed excess of acid may be hazardous Water, as he states, is undoubtedly the best diuretic, but it cannot be accepted that no other substances cause diuresis Carbohydrates in diabetics act as diuretics, while a number of drugs will cause diuresis in normal conditions of the kidney

Perhaps the best classification of nephritis is that offered by Oertel[69]

---

[1] Trinitrotoluene Poisoning Med Press and Circular 1916 n s 10~, 534

[69] Oertel Horst The Classification of Nephritis, Arch Int Med June 1913 p 653

1 Simple nephritis
2 Degenerative and exudative nephritis
3 Degenerative and productive nephritis
4 Productive nephritis
  (*a*) Diffuse
  (*b*) Focal and patchy
5 Senile atrophy or nephritis due to arteriosclerosis of the kidney Senile kidney

1 The first class of nephritis is accompanied by all the classic symptoms of inflammation with exudate and with desquamation and proliferation of parenchyma cells in some cases Recovery may be complete

2 The second class shows degeneration and necrosis exudate with hemorrhage, proliferation of parenchyma cells and formation of casts in abundance

3 The third class shows not only degeneration and most of the signs and conditions of the second class, but also a production of fibrous tissue and shrinking of structure, with thickening of the renal arteries

4 The fourth class is identified by the development of new kidney-secreting structure

In the diffuse type of inflammation not only is new tissue formed, but also there is a growth of connective tissue and distortion of the tubules

In the focal form, hyaline swelling and fatty degeneration occur in the intima of the small renal vessels, causing impaired function of the parts of the kidney fed by these blood vessels, or, in extreme cases, actual obliteration, marked by a granular appearance of the kidney

5 The fifth class or arteriosclerotic kidney consists of a noninflammatory degeneration

While the foregoing classification is based on pathologic findings and may be difficult to interpret clinically, it is scientific and recognizes the well known interlocking and overlapping cases of nephritis An exact diagnosis of the pathology of a kidney cannot be made by the urinary or blood findings, we can determine the signs and symptoms and the amount of excretion and retention only at a particular date and hour Frequently we cannot accurately prognose the length of life of the patient, even when he is moribund

The old classification of parenchymatous and interstitial nephritis is not sufficient Most parenchymatous nephritis would probably be more aptly termed diffuse nephritis Probably no interstitial nephritis occurs without more or less parenchymatous degeneration, if not inflammation Possibly the senile sclerotic kidney may be termed more or less purely interstitial We may recognize the factors which tend to produce acute or chronic inflammation of the kidneys, and the factors which are most likely to cause a parenchymatous and diffuse or interstitial type

ETIOLOGY

The facts that albumin and casts are frequently found in the urine in various ailments, and that in incipient and advanced nephritis acute disturbances of the kidneys frequently occur have not been better demonstrated than by the findings of Brown and Cummins[70] in the cases of 7,000 patients admitted to the San Francisco Hospital, the majority of whom were men between the ages of 20 and 60 They found albumin and casts in 594 patients, although only thirty-eight of these were admitted for nephritis They found that venereal infections, the more serious general infections and alcohol played a prominent part in the previous history of chronic nephritis They draw the logical conclusion that a kidney once injured is later more susceptible to irritations

Localized nephritis is known to be caused by bacteria from some acute infection, pyemic in type, as with infarcts, or by a more chronic localization, as in tuberculosis Localized or general nephritis may be caused by some hidden chronic infection, as mouth or nose infections, or a more or less acute nephritis may be the result of an acute general infection, such as scarlet fever, diphtheria, pneumonia, cerebrospinal fever or smallpox All the above mentioned infections ordinarily are the sources of diffuse nephritis, perhaps primarily parenchymatous

Doubtless if the urine should be examined during the first stage of every acute infection, traces of albumin would frequently be found The backache and high fever accompanying these infections is probably due to kidney congestion, caused by toxins of the bacteria, or by the disturbance of metabolism, especially protein Probably, in the more simple general infections, the bacteria rarely reach or disturb the kidneys, but their toxins may affect these organs

In lead poisoning, in syphilis, in prolonged cardiac insufficiency in hypertension, in arteriosclerosis and in gout, although the nephritis may be more or less profuse, the interstitial form usually predominates Prolonged intestinal disturbances, liver insufficiency, repeated strenuous physical labor, and polyglandular (ductless gland) disturbances are apt to cause chronic disturbance and chronic inflammation of the kidneys Prolonged and repeated kidney congestion, due not only to cardiac insufficiency, but also to pressure from some abdominal cause, or to displacement of a kidney, tends to cause one or both kidneys to become infected with chronic inflammation Probably abdominal pressure during pregnancy is a frequent cause of this type of nephritis

The composition of the blood coming to the kidneys represents an important factor in the health of the kidney glands The chief facts to be considered in this respect are whether the blood contains the necessary nutriment, whether it carries elements causing dilatation or contraction of the kidney vessels, whether it carries an extra amount of waste products, drugs or foreign matter difficult of excretion or hard to metabolize or to change chemically into normal excretory products, whether the bulk of the blood coming to the kidneys is too great for the kidney structure to care for properly, or whether the amount of blood is insufficient to cause a proper kidney pressure both for nutrition and for excretion, making the kidney function normal As stated, metabolic, organic or bacterial toxins may irritate or erode the kidney cells and sooner or later cause nephritis

There doubtless is also a nervous control of the kidney circulation and of the kidney activity that at times plays an important part in an acute or chronic disturbance of the kidneys Surgical conditions in the abdomen may reflexly interfere with the kidney function, making kidney tests inaccurate, this is especially true of ureteral, bladder and pelvic disturbances Furthermore, disturbances of many glands, such as the liver, thyroid, suprarenals and pituitary, markedly change the work required of the kidneys

As abnormal, repeated heart strain injures the heart and blood vessels, so repeated overmuscular effort, by increasing the exertion of the kidneys, may injure them

Toxins or irritants absorbed from the intestine or from poisonous foods, cold storage foods, canned foods, or foods containing minute doses of boric acid or sodium borate may, by daily irritation, cause chronic nephritis Chemical irritants such as turpentines, phenols and many aromatic oils or synthetic drugs, under certain conditions, may cause inflammation of the kidney Too great an absorption of silver nitrate may cause acute nephritis, while prolonged use of mercury and arsenic may cause an acute or chronic form of this disease Chloroform and ether may cause temporary kidney irritation

---

[70] Brown P K and Cummins W T A Study of the Etiology of Chronic Nephritis The Journal A M A March 11 1916 p 793

The kidneys generally respond to an increased demand on them by a dilatation of their vessels with an increased general blood pressure Following the ingestion of large amounts of protein or the circulation of irritants in the blood, an increased amount of blood flows through the kidneys in a given time and the excretion of urinary substances is increased, thus the blood is purified The person who is repeatedly poisoned continues for months in apparent health, entirely unaware of the slowly developing chronic changes taking place in his kidneys There comes, however, a day of reckoning, the kidneys, heart and blood vessels gradually work less harmoniously, and the kidney congestions result in chronic nephritis

If the close relation of the kidneys to the skin, relative to excretions is considered, many unexplained albuminurias and attacks of nephritis will be understood The excretion of solids by the skin is increased in this disease, although the total excretion is small

While acute nephritis caused by cold alone is probably very rare, it may be the exciting cause of an already existing subacute or chronic disturbance Chilling of the body at any time increases kidney activity, while warming of the body decreases it

Any disease of the skin which prevents normal perspiration is detrimental to the kidneys, whether caused by burning, erysipelas, scarlet fever, dermatitis exfoliativa, or by any other acute or chronic general inflammation of the skin The larger the area of skin affected, and the greater the inability to excrete water, the greater is the danger which threatens the kidneys The reverse is also true in chronic nephritis the immediate prognosis is more favorable when the skin is soft, moist and healthy, but is less favorable when the skin is dry and harsh

Ether and chloroform anesthesia, especially the latter, which always causes kidney disturbance, by repeated use become a positive menace to the kidneys

Diabetes may be a causative factor in nephritis, as frequently excessive amounts of nitrogenous food are consumed Syphilis may also be an etiologic factor, either per se or through the arsenic or mercury treatment employed to cure it

Chronic alcoholism is perhaps an indirect cause of nephritis since it disturbs the circulation, the liver and the digestion Tobacco, by causing an abnormal blood pressure which finally injures the heart, becomes an indirect cause of nephritis

The recuperative power of the kidneys and the harmless nature of occasional urinary symptoms of nephritis must, however, be recognized Hence, extreme care should be used in diagnosing a case of nephritis When a case is thus diagnosed it should be remembered that if one fourth of the kidney structure is healthy, this is sufficient to prevent serious symptoms Furthermore, diseased parts may recover, or even if hopelessly degenerated, neighboring parts of the kidney may hypertrophy and carry on the extra work

To sum up, heart and blood vessel insufficiency is a common forerunner of inflammation This congestion may be the result of lordosis, or of a floating kidney Prolonged exertion and hard work is a common cause of congestion and albuminuria, as is also profuse sweating, which increases the viscosity of the blood by dilating the kidney vessels [71]

Prolonged low blood pressure and a reclining position associated with serious illnesses, such as typhoid fever and tuberculosis, are detrimental to the kidneys, resulting in extended passive congestion Hence, the patient's position in bed should be changed frequently, just as soon as he is able to endure it

Albuminuria, which frequently follows operations, may be due to the anesthetic, to an abnormal position long retained, such as that in pelvic operations, or to the two combined Hence, anesthesia and abnormal positions on the operating table should be of as short duration as is compatible with efficiency and accuracy of technic

An important fact to bear in mind is that one attack of nephritis apparently breaks down the resistance of the kidneys, and that frequent attacks of albuminuria, which is generally caused by renal congestion, leaves them susceptible to real nephritis

(To be continued)

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies A copy of the rules on which the Council bases its action will be sent on application -W A Puckner, Secretary

TABELLAE DULCES ARISTOCHIN (WESTERN), 1 GR—Each tablet contains aristochin 1 grain, with cocoa, sugar and saccharine as vehicles

(Accepted for inclusion with the appendix to New and Nonofficial Remedies)

Prepared by Western Chemical Company, Inc , Hutchinson Minn

TABELLAE DULCES HEROIN (WESTERN), 1/100 GR—Each tablet contains heroin, 1/100 grain, with cocoa, sugar and saccharine as vehicles

(Accepted for inclusion with the appendix to New and Nonofficial Remedies)

Prepared by Western Chemical Company, Inc , Hutchinson Minn

TABELLAE DULCES NOVASPIRIN (WESTERN), ¼ GR—Each tablet contains *novaspirin*, ¼ grain, with sugar, starch, liquid petrolatum, saccharine, curcuma and oil of lemon as vehicles

(Accepted for inclusion with the appendix to New and Nonofficial Remedies)

Prepared by Western Chemical Company Inc , Hutchinson Minn

TABELLAE DULCES TANNALBIN (WESTERN), 1 GR—Each tablet contains tannalbin, 1 grain, with cocoa, sugar and saccharine as vehicles

(Accepted for inclusion with the appendix to New and Nonofficial Remedies)

Prepared by Western Chemical Company, Inc , Hutchinson Minn

TABELLAE DULCES TERPIN HYDRATE WITH HEROIN (WESTERN), 1/100 GR—Each tablet contains terpin hydrate, ½ grain, and heroin, 1/100 grain, with cocoa, sugar and saccharine as vehicles

(Accepted for inclusion with the appendix to New and Nonofficial Remedies)

Prepared by Western Chemical Company Inc , Hutchinson, Minn

THE EARLY DIAGNOSIS OF WHOOPING COUGH BY CULTURAL METHODS

The statement is frequently made that not enough is being done to control and reduce the spread of whooping cough Thus Morse[1] has recently voiced a strong demand for increasing efforts in this direction, and he urges an educational campaign to convince physicians and the general public of the seriousness of whooping cough and of the necessity of a much stricter enforcement of notification and isolation than is now practiced It is accepted that the disease is caused by a small bacillus discovered by Bordet and Gengou, which is transferred in the sputum from the sick to the well This bacillus is probably present in the respiratory tract from the earliest moment of infection, and it is demonstrable in the sputum long before the diagnosis of whooping cough can be made from the symptoms

In order to reduce the chances for spreading pertussis, the disease must be recognized much earlier than is now the rule, and the patients properly isolated while they are still in the catarrhal stage when, in fact, they are the most infectious In the early stages of the disease there are not available any easy short cuts to diagnosis by way of immunity reactions because the complement-fixing and other immune substances have not yet developed sufficiently The whooping cough bacillus is hardly distinguishable from the influenza bacillus on direct microscopic examination The only remaining method now known by means of which a definite diagnosis can be made in the early stages of whooping cough is the isolation of the bacillus from the sputum by cultural methods Morse apparently recognizes that this is quite true, but dismisses the method as too difficult and complicated for practical purposes, a conclusion from which one might well differ because the technical procedures are certainly no more difficult and no more complicated than many now in daily use for practical ends

Chievitz and Meyer[2] in Copenhagen have been studying the sputum in whooping cough by cultural methods They find the bacillus present in practically all cases when the catarrhal stage is well established In making the cultures it is necessary to fish out mucopurulent flocculi from the last portion of the expectorate, to wash them in sterile salt solutions, and rub them over the surface of the medium (blood-potato-agar) The characteristic colonies resemble minute drops of mercury — polished and glistening — and appear after an incubation of about four days The final step is agglutination of the bacilli in the colonies by the serum of rabbits or horses immunized with *Bacillus pertussis* In very small children or when there is no sputum the Danish workers obtain good results by making the patients cough against plates of culture medium held a few inches away from the mouth This simple way is of value especially at the very beginning of the infection When the attack has lasted about four weeks or so, cultures are usually no longer obtainable, and the Danish regulations now permit release from quarantine after four weeks and two negative cultures

It appears, then, that we have it in our power to secure the benefits which would result from the diagnosis of whooping cough earlier than can be made from the symptoms alone To repeat, the cultural diagnosis of whooping cough in the early stages, when it is most infectious and isolation would accomplish the most, does not appear to be so inherently difficult as to be really impracticable Arrangements should be made for the introduction and use of this early diagnosis by culture because thereby sickness can be prevented and life saved

NOCTURIA

The efficiency of the functions of different parts of the alimentary tract have long been studied experimentally and for purely diagnostic purposes by the use of test meals and test diets It has lately been proposed to investigate somewhat similarly the presence or absence of impairment of renal function, both qualitatively and quantitatively, by the employment of a "nephritic test meal" The application of this idea, the clinical development of which we owe primarily to Hedinger and Schlayer,[1] has recently been carried out extensively by Mosenthal[2] It has been ascertained that the nephritic test meal, when duplicated on the same patient, yields identical results, provided the clinical condition has not changed As selected by Mosenthal, the dietary contains approximately 13 4 gm of nitrogen, 8 5 gm of salt, 1,760 c c of fluid, and a considerable quantity of purin material in the form of meat, soup, tea and coffee

The most important findings in the urine of healthy persons on the nephritic test meal are exemplified in the differences between the day and night urines Whatever the quantity of urine excreted during the day by such normal persons, it is found that the night specimen varies within very narrow limits It is high in specific gravity (1 016, but usually 1 018 or higher), high in its concentration of nitrogen (above 1 per cent), and small in volume (400 c c or less), regardless of the quantity of fluid ingested or the amount of urine secreted during the day period

---

[2] Mosenthal H O Renal Function as Measured by the Elimination of Fluids Salt and Nitrogen and the Specific Gravity of the Urine Arch Int Med November 1915 p 733

Nocturnal polyuria, or nocturia, on the other hand, is one of the earliest symptoms of renal disease, according to Mosenthal By this is not meant a frequent voiding of urine — a "nocturnal pollakiuria" — not accompanied by an increase in the total usual volume of 400 c c, but rather an increased volume of night urine True nocturia may be found when few other signs of nephritis are detectable The specific gravity and the nitrogen concentration of the night urine are lowered as soon as the kidney function becomes involved When the nephritis becomes severe and chronic, an advanced degree of functional inadequacy of the kidney is indicated by a markedly fixed and low specific gravity, a diminished output of both salt and nitrogen, a tendency to polyuria, and a night urine showing an increased volume, low specific gravity and low concentration of nitrogen Such functional pictures, we are told by Mosenthal, are not confined to nephritis Diminished renal function is present, however, and its cause must be sought for in many directions — the urinary passages, the blood, or the kidney itself

The fundamental features of the ominous nocturia also apply to other conditions than those established by this special nephritic test diet Addis and Watanabe[3] have recently collected numerous data in regard to the volume of urine of persons on a constant water intake They find that the volume of urine in normal persons on a constant diet with the same water intake is extremely variable for any single day or part of a day The average volume of the last three days of the diet when the water intake was 2,070 c c varied in twenty individuals from 1,013 to 1,712 c c for a twenty-four hour period, from 684 to 1,195 c c for the first twelve hours of the day, and from 501 to 788 c c for the first eight hours of the day The percentage of the twenty-four hour volume excreted during the twelve hours of the night did not exceed 47 per cent in any subject, when the volumes for the last three days of the diet were averaged When the kidneys are diseased, however, the volume of urine passed at night is often larger than the day urine

These studies are of particular value in furnishing criteria for what constitutes a true nocturia, that is, an abnormally high proportion of night urine With this established by some dependable method, the existence of renal imperfection may be suspected even when other signs more familiar have not made their appearance As in so many other departments of medical practice, here, too, absolute rules applicable to every case cannot be laid down There are too many complicating variables in the human physiologic mechanism to permit the application of hard and fast directions Christian[4] has noted that in patients with pernicious anemia the disease is accompanied by a disturbance of renal function, as measured by renal dietary tests, which is similar to that found in patients with advanced chronic nephritis In these patients there is no evidence of chronic nephritis, and the disturbance appears to be due to the anemia, decreasing with the subsidence of the severity of the anemia unless this is maintained so long that a permanent disturbance of renal function ensues Christian properly points out that caution is required in the interpretation of the results of such tests in patients supposed to have nephritis For, he states, if a patient with moderate nephritis, as indicated by other tests and by symptoms, happened to have a fairly severe anemia, the latter factor might give to the picture of renal excretion a fixation suggestive of advanced nephritis, and lead to a prognostic interpretation which was unjustifiably poor Consequently, it will be well to consider the element of anemia when drawing conclusions from dietary renal tests applied to patients with nephritis, though it is not probable that this will prove a complicating factor in many cases, for usually the degree of anemia in patients with nephritis is slight — much less than their pallor would suggest

THE VENEREAL DISEASE PROBLEM—II

Recommendations of the British Royal Commission on Venereal Diseases

Among the topics considered by the comprehensive report of the Royal Commission on Venereal Diseases[1] are the prevalence and distribution of the venereal diseases, the unreliability of statistics as shown by death registration, the effects of the venereal diseases on those primarily infected and on their offspring, and the economic effects of the venereal diseases On the question of notification the commision reports adversely, saying

> We think it clear that if a case for notification of venereal diseases is to be established it must be based upon the assistance which notification would afford to the treatment of the individual, and the consequent protection of the community, and not on the ground that it would facilitate general preventive measures The main objection which has been urged against notification of venereal diseases is that it would actually do more harm by deterring people from seeking treatment, and by driving them more than ever into the hands of unqualified persons

The commission believes it possible that the situation may change after the general measures for treatment which it has recommended have been for some time in effect, and after the public has been educated in the venereal diseases, but it does not regard notification as now practicable. It thinks that anonymous notification would not be satisfactory. The report lays stress on the need for increased attention to the venereal diseases in the scheme of medical education. It urges the necessity for opportunity for special study of the venereal diseases, and suggests that one of the functions of the clinics for venereal diseases which it recommends shall be the affording of opportunities for study to medical students and practitioners. The commission believes it is important that every effort should be made to enlighten the public as to the seriousness and the contagious dangers of the venereal diseases and their distressing after-effects, and that there should be a franker attitude toward these diseases. It holds that children under 14 are unfitted for this instruction. To older children it recommends such instruction, but points out the difficulties and the objectionable character of many well intentioned books and pamphlets which have been issued on the subject. It considers that no such publications should be countenanced by educational authorities unless they bear authoritative endorsement. In the case of England it recommends that such publications should have the endorsement of the National Council for Combating Venereal Diseases. The commission gives its endorsement to the various organizations which have been formed for promoting the welfare of youth, for teaching sexual morality and for developing character, and adds, "The fact that we recommend that free treatment should be provided for all sufferers makes it in our opinion, all the more necessary that the youth should be taught that to lead a chaste life is the only certain way to avoid infection."

[4] Christian H A Renal Function in Pernicious Anemia as Determined by Dietary Renal Tests Arch Int Med October 1916, p 429

[1] The Venereal Disease Problem—I editorial, The Journal A M A Feb 3 1917 p 375

The main emphasis of the report is placed on the necessity for early and accurate diagnosis and for early and continuous treatment. The commission finds that present opportunities for diagnosis and treatment are entirely unequal to the needs of the situation. In recommending improvement in the facilities for treatment it considers that existing institutions should be utilized as far as possible, that new institutions should be founded only when it is unavoidable, and that the new clinics should be part of general hospitals, and not stigmatized by being devoted to venereal diseases alone. It is convinced that existing hospital facilities, with necessary extensions in certain localities, would furnish all of the institutional needs of the situation, but it believes that no adequate system of treatment is possible unless responsibility for it is assumed by the state. The institutions provided must be available for the whole community. To that end they should be made accessible, and evening clinics should be provided. They should be free from embarrassing restrictions. Patients should be given treatment regardless of their residence, and should be free to go to clinics outside of their own district. Persons able to pay should, if possible, be sent to their physicians, but even they should not be refused treatment in the public institutions if they are unwilling to go to a private physician. It is pointed out that treatment to be effective in controlling the public dangers of the venereal diseases must be continued until a cure, or freedom from infectiousness is attained, and that effective provisions must be made for seeing that treatment is continued through the infectious period. Compulsory treatment is suggested for the delinquent.

The commission believes that any government scheme which is carried into effect must rely largely on the education and the cooperation of the medical profession, and must depend in the end for its success on the general practitioner, who constitutes "the first line of defense in the community." The report emphasizes strongly the great damage which is done in the treatment of venereal diseases by unqualified practitioners, by drug store prescribing, by quacks and, as well, by less vicious but ignorant practitioners of special sects, and strict measures to prevent such treatment are recommended. The commission believes that all advertising of remedies for venereal diseases should be prohibited by law.

Readers who have noted the first steps in this campaign will realize that the commission has done its work well. On many hotly debated questions it has offered a judicial, conservative opinion. Its findings are not purely local, but show a consideration and a broad grasp of human nature, economic conditions and social problems that could be held only by so representatively constituted a body as this commission was.

THE PROBLEM OF KIDNEY FATIGUE

In physiology and medicine, as in other sciences, the introduction of new methods of observation and experiment usually leads to new facts which may necessitate a revision of our older theories. In former days some of the intellectual disciplines advanced almost solely by the single method of accumulating new data. The older natural history thus at first contented itself largely with the description of more and more species. At length however, there came a time when the storehouse of observations had to be inventoried, and its contents arranged in some orderly fashion. The procedure of taking stock of the known always raises questions which carry us into the field of the unknown.

The study of the distribution of the so-called waste products of the body, made possible by improved chemical methods of blood and tissue analysis, has been fruitful in enlarging the horizon of our knowledge. Urea, creatinin, uric acid and other familiar urinary components can now be followed back farther on their path from the threshold of formation in the metabolic transactions of the organism. It is not so long ago since the failure of these substances at times to appear in the urine in expected amounts gave rise to the conclusion that, owing to some renal insufficiency, they were being accumulated in the blood itself Retention and uremia were satisfactory expressions to account for a diversity of pathologic symptoms in which defective kidney function was believed to play a part Today we can advance beyond the stage of mere guesswork in many of these cases Renal function can be tested quite accurately in a number of ways, furthermore, the blood can be examined, without any serious technical obstacles, for the suspected evidences of unexcreted waste products

Apparently unlike responses of the kidneys to tasks of excretion imposed on them experimentally by investigators have led to the assertion of the existence of what might be called "kidney fatigue" [1] This idea is somewhat in harmony with the observed fatigue or temporary exhaustion of other glandular structures, such as the pancreas and salivary glands, in which the outpouring of some specifically accumulated product is assumed to entail time for its replacement by cellular synthesis

It is by no means so certain, however, that an equally active and immediate part in the work of urine formation is played by the kidney cells Without denying their physiologic cooperation, it must be admitted that physical and physicochemical processes serve to promote no small portion of the renal performance So far as such changes are concerned, there is little occasion to expect any signs of fatigue This is in accord with the belief of Ambard that the kidney manifests no intrinsic variability in function He maintains that if the concentration in the blood and in the urine of the substance excreted is known, the action of the normal kidney may always be predicted with mathematical accuracy According to Ambard there exists, for any person, a constant relation between the concentration of urea in the blood and its excretion in the urine A study of Ambard's "constant" under conditions of extreme variation of functional demands may therefore be expected to give evidence for or against the existence of renal fatigue

The work of Schlayer and others on water and chlorid excretion by the kidneys has been interpreted as indicative of a wide variability in kidney action even under the same conditions Addis and Watanabe[2] have approached the debated question by a study of the rate of excretion of urea administered to young healthy adults who were on a constant diet carried through in order to obtain detailed information as to the range of variation in the function of the normal kidney under uniform conditions In a large number of experiments on such persons, they found no evidence of variability in kidney action in the work of excreting preformed urea added to a constant diet Such variation as was found in the amounts of urea excreted could be fully accounted for as arising from extrarenal factors It is concluded, therefore, that the normal kidney under constant conditions is characterized by the possession of a high degree of constancy of function The rate of excretion of the administered urea during successive periods of the twenty-four hours showed that the repetition of large doses of urea did not elicit the condition which has been described as "kidney fatigue" A fraction of the urea which was administered remained in the body after twenty-four hours This urea was not retained because of any failure on the part of the kidneys to eliminate it, for the amount retained was no larger when 40 than when 20 gm of urea were taken

In connection with these experiments it should be recalled that administered urea is not accumulated in the blood alone, but exists, as Marshall and Davis[3] have shown, for the greater part distributed to the tissues, from which it is gradually withdrawn for excretion by the kidneys Indeed, the major part of ingested urea soon enters the tissues, so that its concentration in certain organs is approximately equal to its concentration in the blood The tissue reservoir, so to speak, for the storage of large quantities of urea temporarily present in the body has not been known until quite recently It serves most advantageously as a regulatory factor to avert undue concentration of urea at any moment in any particular locality Retention of this substance may accordingly be possible because it is never brought to the kidneys for excretion But even when exceptionally great loads are imposed on the kidneys, as occurred in the successive increase in urea-eliminating demands over several days in the experiments of Addis and Watanabe, the existence of a condition approximating fatigue of these organs could not be detected

EPIDEMICS OF TYPHOID FROM WATER SUPPLY

A number of typhoid epidemics have been reported in this country which have been due to the contamination of a good public water supply with water drawn privately from an auxiliary source, i e, bad water has been mixed with good in a double system of connected pipes The purpose of the dual system of water piping in its origin was largely economical It has been the policy of fire insurance and underwriter companies to require of their industrial risks the instalment and maintenance of two systems of fire service, one from the public water supply, the other from an independent source The aim of this requirement is to afford additional fire protection by automatic sprinklers and the like in case either system is put temporarily out of commission. In many parts of the United States such a double system of water piping in factories has existed for more than twenty-five years. It is natural, perhaps, that in most instances little attention should be paid to the sanitary quality of the secondary private supply, designed only for emergency use, and that this supply should be obtained as a rule from the most convenient source, often a highly polluted stream on which the factory is situated. The necessity for the separation of the two systems, however, appears to have been generally recognized, but it was for a long time supposed that the mixing of the waters could be prevented by check valves which were placed in the piping system.

---

[2] Addis T and Watanabe C K The Rate of Urea Excretion II The Rate of Excretion of Administered Urea in Young Healthy Adults on a Constant Diet Jour Biol Chem 1916 **27**, 249

[3] Marshall E K Jr and Davis D M Urea Its Distribution in and Elimination from the Body Jour Biol Chem 1914, **18**, 53 The Distribution of Urea in the Body, editorial, THE JOURNAL A M A, Sept 26 1914 p 1115

One of the first events to shatter confidence in the efficiency of the check valves was a typhoid outbreak in Lowell, Mass., in the summer of 1903. What happened at that time is told in the report of the Lowell Water Board:

> On Saturday, July 18, there occurred a fire on the Merrimack Corporation, at which the Locks and Canals reservoir was drawn upon to such an extent that the pressure in their pipes went below the city pressure. Consequently, the check valves between the two system opened, and the city water flowed into the Locks and Canals' pipes until the fire was extinguished. Some time after the Locks and Canals Company started pumping it was found that their reservoir did not fill, and on investigation it was found that a check valve situated on the Massachusetts Corporation near the corner of Canal and Bridge streets had failed to close, and water from the Locks and Canals was flowing into the city mains. Within a few days an epidemic of sickness appeared resembling cholera morbus, and later developed many cases of typhoid fever.

It seems now to be generally admitted by engineers that even modern check valves are not to be depended on. In the Lowell case the check valve was made especially for the Locks and Canals Company, was said to be substantial and well constructed, and had been found in supposedly good working condition one week previous to the fire. The general reliability of check valves is apparently not very high. One water works superintendent expresses his opinion feelingly: "Any one who has ever had much experience with check valves knows that they are an invention of the devil."

Outbreaks of water-borne typhoid caused by the dual water pipe system are far too common. They have been reported among other places at Winnipeg and Toronto, at Omaha, at Circleville, Springfield and Van Wert, Ohio, and have been suspected in many other localities. In Philadelphia, in 1913, numerous typhoid cases developed in a section of the city supplied with the excellent public water from the Torresdale filtration plant, at the same time that other parts of the city supplied from the same source were typhoid free. Bacterial examination of the tap water in the affected district gave evidence of contamination. Inspection of manufacturing establishments along the Delaware River water front disclosed the existence of a number of factories having dual connections with the polluted river water. When complete severance of the filtered water supply from the private source was enforced, typhoid diminution followed.

One of the most recent epidemics attributed to this cause occurred in September, 1916, at Elgin, Ill., where the employees of a large watch factory suffered severely. This disastrous outbreak has had an especially instructive sequel since under the Illinois Compensation Act the death claims — eighteen in number — against the watch company have been settled through the agency of the State Industrial Board. The action of the manufacturing corporation seems to have been exemplary since the very onset of the epidemic; not only have the death settlements been adjudicated with the complete cooperation of the factory officials, but also during the progress of the epidemic the medical and hospital responsibility and expenses were promptly assumed by the watch company. It is estimated that the actual outlay by the manufacturer in behalf of the typhoid sufferers will be approximately $100,000.

There is little doubt that typhoid cases which can be traced directly to the drinking water furnished by an employer come properly within the provisions of such laws as the Illinois Compensation Act. In such cases it can be reasonably maintained that the employee is subjected to a risk "peculiar to the employment and not common to the neighborhood." A significant problem is raised for manufacturers if the drinking of infected water furnished by the employer can be made one of the causes of injury or death for which the employer must pay compensation.

There seems today sufficient reason for demanding that under no circumstances shall a connection be permitted between the pipes of a public water supply and a polluted source. Complete and absolute separation of the private and public pipes must be insisted on. It should not be difficult to solve the problems of adequate fire protection and industrial convenience without jeopardizing the public health. This matter may well receive more consideration from health authorities and other public officials than is given it at present. We are not aware that the sanitary quality of a factory water supply is given adequate attention by factory inspectors. Experience has shown, however, that the private water supply of an industrial establishment is too often the cause of preventable illness and death, and is a health hazard to which searching attention should be given. Health officials and factory inspectors everywhere should ferret out these dual water connections and summarily eliminate them.

A Motto for a Pathologic Amphitheater.—The dissecting room at Toulouse is decorated with an inscription which would be singularly apt for a necropsy theater: *Hic locus est ubi mors gaudet succurrere vitae*. "This is the place where death delights to help life."

Current Comment

THE OUTPUT OF CALCIUM AND MAGNESIUM IN MAN

It can scarcely be doubted that chemical pathology has many chapters in which perversions of the metabolism of the alkali earths, calcium and magnesium, are concerned in some degree The role of these elements in the living body is hardly known in even its most superficial aspects, and whether we happen to have in mind the bones and their development, the blood, the endocrine glands, the nervous tissues, or some other structure, in each case calcium or magnesium are as yet mere incidents in the story of some interesting phenomenon Whether an undue proportion in which they chance to be found is the result or the underlying cause or merely an unrelated incident in the problem under investigation is rarely ascertainable Calcium and magnesium enter the body with the food and leave it with the excreta The paths of excretion are diverse, but we scarcely know the details of even a single feature of the transit of these two important mineral nutrients through the organism A recent writer[1] was well justified, therefore, in saying that it would be fortunate if calcium metabolism would receive as much attention as basal metabolism has lately received It seems axiomatic also that, if we would know more about such diseases as osteomalacia, rickets, osteoporosis and infantilism, we must first have forthcoming sufficient data on the normal behavior of the body with which to compare the findings in these pathologic states It is not always realized to what a large extent calcium leaves the body with the feces The average daily urinary and fecal output of calcium calculated as oxid over periods of five days for five apparently normal persons, ranging in age from 13 to 70 years, was

Urinary excretion	0 175 to 0 619 gm of CaO
Fecal excretion	0 413 to 0 801 gm of CaO
Total daily excretion	0 588 to 1 420 gm of CaO

The predominant belief that the output of calcium exceeds that of magnesium in the urine appears to need revision According to Nelson and Burns,[2] who examined twenty-five apparently healthy persons living on a mixed diet, in seventeen the daily output of calcium was larger than that of magnesium, and in eight, the magnesium predominated over calcium The largest amount of calcium (calculated as oxid) excreted in one day was 0 488 gm , of magnesium (calculated as oxid), 0 416 gm The smallest amount of calcium was 0 099 gm , of magnesium, 0 118 gm Either calcium or magnesium may therefore be excreted in the larger amount in the healthy person The preponderance of one element is as indicative of normal behavior as the other Furthermore, the results indicate that each person exhibits a constant behavior as to whether calcium or magnesium shall be greater in amount in the urine voided In the case of the three persons examined over the five day periods, of nineteen determinations only two showed a daily output of calcium exceeding that of magnesium Such statistical facts are the beginnings of what ought to become in the not too distant future a comprehensive investigation of the metabolism of the mineral nutrients

MEDICAL PREPAREDNESS

While the severance of diplomatic relations with Germany does not necessarily mean war, it unquestionably brings us, as a nation, to a point at which a state of war with a European nation must be considered as a possibility As usual in times of general excitement, many of our newspapers are filled with rumors, as many of our citizens are filled with hysteria In emergencies, physicians, of all men, are expected to keep cool and to be able to act efficiently This is a duty of the profession as a whole, as well as of individuals If war comes, the role of the medical profession will be an important and responsible one That these responsibilities will be assumed without hesitation and borne with credit is beyond question In case of conflict with the Central Powers, it is difficult to see, under present conditions, how land forces could be employed, at least in the near future Service would probably be limited to work on shipboard For this, the Bureau of Medicine and Surgery of the Navy has its regular corps, as well as the Navy Medical Reserve Whatever may be the outcome of the present situation, the medical profession, and especially the younger men, should understand that the Army Medical Corps needs more men and that the navy is anxious to secure additional medical officers Those physicians not needed or adapted to regular military service should at least affiliate themselves definitely with the national Red Cross, through its various local branches, and prepare themselves, either now or for the future, to be of service

THE RESPONSE OF A SINGLE KIDNEY TO EXCRETORY STRAIN

The capacity of one of various paired organs, notably the kidneys, to execute satisfactorily the functions which are ordinarily shared by the two organs has often been demonstrated One eye, one lung or one kidney frequently fills suitably the ordinary needs of the individual deprived of the other organ After ligation of one ureter, or extirpation of one kidney, the remaining kidney occasionally functions even more efficiently than both kidneys before the operation Under extraordinary needs, however, the limit of working capacity most readily manifests itself Addis and Watanabe,[1] taking a somewhat arbitrary index of functional capacity, have demonstrated this ability anew The work the kidney was called on to do in their experiments was represented by the urea in the blood The work it did was evidenced by the urea in the urine Renal capacity was represented by the ratio between the work done and the work to be done This was studied before and after ligation of one ureter whereby one kidney was excluded from participation in the excretory process Extra renal work was supplied by injections of urea into the subject When no urea was given there was no decrease in the renal capacity because of the extirpation The added strain was within the capacity of the remaining kidney When the work to be done was greatly increased by the injection of urea, however, the strain which before operation had stimulated both kidneys to greater efficiency was too much for the remaining kidney, its maximal rate of work was less than the rate of increase in the work to be done, and there was a consequent decrease in the ratio This outcome, they point out, illustrates an important principle in the measurement of kidney function It shows that function may be entirely normal under ordinary conditions, and yet not so under strain The administration of a large quantity of urea before the renal capacity is determined not only has the advantage of tending to equalize the experimental conditions, it may also bring to light latent deficiencies The phenolsulphonephthalein test fails to do this Representing, as it does, the excretion of a minute amount of a foreign substance, no strain is imposed by this test on the capacity of the kidneys Its main value lies in indicating the presence and perhaps the degree of pronounced renal disease Doubtless some other test of a type like the experimental one just reviewed, which will place a strain on the kidney tissue in excreting an unusual amount of some normally present catabolite, such as urea, will better serve for the diagnosis of a latent defect A further search in this direction may therefore seem worth while

THE SARGOL VERDICT — AN INSPIRATION

The Sargol verdict, briefly referred to under New York news last week, is one of the most encouraging incidents in the movement toward truth in advertising Sargol was a nostrum of the get-fat-quick variety, as an alleged "flesh builder" it was advertised extensively and intensively by its exploiters Two facts it had in its favor it was not advertised, directly at least, for the cure of disease and it contained no dangerous or habit-forming drugs The chief, if not the only, objection to the nostrum was the simple fact — now a matter of court record — that its sale was an outrageous and impudent fraud To one not familiar with the curious mental slant of certain advertising managers this last objection might seem all-sufficient to bar advertisements of Sargol from all decent newspapers and magazines Not so! The attitude of some newspaper publishers on the subject of "patent medicine" advertising is this

"Does the preparation contain any habit-forming or dangerous drugs?"

"No!"

"Then take the advertisement"

Other publishers add another question

"Is the product recommended for serious diseases?"

"No!"

"Then the copy is acceptable"

The fact that a nostrum is sold under claims that are obviously or demonstrably false is brushed aside with the sophistry that claims made for "patent medicines" are "matters of opinion!" That Sargol passed muster on the two questions just propounded doubtless explains why many newspapers and magazines sold their space to the exploitation of this medical fake From a legal point of view the Sargol case was remarkable in that the essential question involved was fraud — not danger to the public health, not a violation of some drug law — just simple, elemental fraud! The case, which was a criminal one, lasted thirteen weeks, the defendants, who were shown to have made over half a million a year, had the wealth and the influence of the nostrum fraternity behind them Yet the Government won! Attorney F J Cregg and his associates, on whom fell the burden of protecting the public, can justly feel proud of having performed a notable public service Especially will the ever-growing army of men who believe in honest advertising rejoice in the outcome of this case For it means that we are brought materially nearer the time when the man with a worth-while product and a desire to sell it honestly will not be handicapped by having his goods placed in juxtaposition with confidence-destroying humbugs, medical or otherwise

PIDAN — AN ORIENTAL FOOD

Food conservation is not a novelty which has come into vogue with the introduction of cold storage plants or chemical preservatives All sorts of procedures for desiccating, smoking, pickling and otherwise handling perishable foods have been known almost from time immemorial Edible products are often saved from spoiling by being converted into new forms of food materials, as cheese is prepared from milk, or catsup from tomatoes The Chinese and other Oriental peoples preserve eggs in an analogous manner by making an altered product out of them This food material, known as pidan, has recently received an extensive examination in the laboratory of food chemistry of the Department of Home Economics at the University of Chicago[1] Pidan is made on a factory scale from ducks' eggs The latter are kept in an infusion of black tea, lime, salt and wood ashes — obviously an alkaline solution — for nearly half a year, much as eggs are preserved in solutions of sodium silicate in this country They are then drained and coated with rice hulls, whereupon they are ready for the market The taste of the pidan is characteristic and the odor markedly ammoniacal There is a tendency for uninformed persons to class such products unreservedly with what are commonly termed rotten eggs This may not be justifiable Pidan has no odor of hydrogen sulphid and, we are assured, does not closely resemble so-called decomposed eggs Noteworthy chemical changes do, however, attend the long storage process in the formation of pidan The Chicago investigators state that water in large quantities has been transferred from the white to the yolk, and water has been lost from the white to the outside The ash and the alkalinity of ash have increased in a way similar to that of other eggs preserved in alkali The ether extract has decreased and its acidity is high Both total and lecithin phosphorus have decreased The non-coagulable nitrogen has increased and also the ammoniacal nitrogen, the latter to an extraordinary degree, and the amino nitrogen is high From these changes the conclusion is drawn that decomposition of the egg protein and the phospholipoids has taken place The production of pidan from the fresh eggs is probably brought about through the agency of the alkali, bacteria and enzymes Like cheese, the product is eaten without being cooked

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities new hospitals education public health etc)

CALIFORNIA

Personal—Dr Edwin J Boyes, Oakland, was seriously injured in a collision between a Southern Pacific electric train and his automobile in Oakland

Book Night—The San Diego Medical Library held its annual 'Book Night" January 30 Each member was asked to contribute at least one textbook on medicine

Proposed Consolidation of State Boards—A bill introduced in the senate proposes to abolish the state boards of dental examination medical examination, optometrists and embalmers and to consolidate them with the state board of health This would mean the saving of about $35 000 a year to the state The act also provides for three lay members on the state board of health, who shall receive a salary of $2,400 a year

Psychopathic Hospital Urged—A bill prepared by the state board of health carrying with it an appropriation of $500 000 provides for the establishment of a state psychopathic hospital to be located near the University of California Medical School in San Francisco to be governed by the university regents with the professor of psychiatry as ex officio director The hospital is to provide not only a research laboratory but treatment for all patients requiring special or intensive study for a short period

ILLINOIS

Personal—Dr William L Hanson, Belleville, has left for England where he has received an appointment in the British Hospital Medical Service

Tuberculosis Survey—The Illinois Tuberculosis Association is arranging for a tuberculosis survey of LaSalle Adams, Morgan, McLane, Champaign, Livingston, Ogle and King counties

Proposed Consolidation of Boards—Bills reorganizing the state executive department in accordance with the plans of Governor Lowden have been introduced in the house and senate Under the proposed plan the department of registration and education is to include the bureau of registration, which will have charge of the licensing of physicians, dentists, pharmacists, optometrists, barbers, nurses and all other members of professions and trades for whom state certificates are necessary The bill also transfers the state food commission from the department of health to the department of agriculture

Chicago

Personal—Dr Lowell F Ingersoll was run over by a street car, January 22, and sustained severe injuries of the foot

Heat Stroke Research—The directors of the Fenger Memorial Association have made a grant of $400 for research on heat stroke

Dr Billings Ill—Dr Frank Billings was taken ill with pneumonia on Saturday, February 3 The latest reports are that he is progressing favorably

Internship Examinations—Examinations for internship in Cook County Hospital will be held March 13 to 15 Graduates of medical schools in Cook County are eligible

Free Water for Hospitals—An ordinance fixing the license fee for hospitals at $50 and granting free water to institutions was recommended by the committee on health of the city council, February 1

Municipal Tuberculosis Sanatorium—Dr Charles P Caldwell, president of the board of directors of the Chicago Municipal Tuberculosis Sanatorium, proposes the establishment of a tuberculosis diagnosis station for each side of the city and states that two of these stations can be completed by October if the project is approved

Clinic Week for Women Physicians—The medical women of Chicago announce a clinic week to be held in Chicago, February 12 to 16 Clinics will be held at many of the leading hospitals and special lectures will be given on eugenics and social hygiene A schedule of the clinics may be obtained from Dr Rachel Watkins, secretary of the Medical Women s Club, 25 East Washington Street

INDIANA

Vaccination Ordered—The city board of health of Terre Haute has issued an order that all of the 11,000 pupils of the public schools must be newly vaccinated for smallpox unless they can show certificates of vaccination within seven years About thirty cases have been reported so far in Terre Haute

Personal—Dr Henry O Bruggemann Fort Wayne, president of the local health board sailed from New York for Vienna for Red Cross work, February 3——Dr Arett C Arnett Lafayette, commander of Ambulance Company No 2 Ind N G, gave a talk before the Tippecanoe County Medical Society, January 23 on "Conditions on the Mexican Border' ——Dr Brown S McClintic, Peru, after three years' service with the Russian army is on his way home by way of China——Dr Paul F Martin, Indianapolis, who went abroad last May under the auspices of the American Relief Expeditionary Association, is now in charge of 2,000 beds in the military hospital at Pardubitz Austria——Dr Donald C McClelland Lafayette, M C, Ind N G, has returned from service on the southern border

IOWA

Summer School for Physicians—The University of Iowa announces that it will give a summer course in medicine during June and July next The course will cover four weeks beginning June 18

Hospital Property Purchased—The Buchanan County Hospital Committee has purchased a site for $7,000 More than $60 000 of the $75 000 required for the establishment and equipment of this hospital has already been subscribed

Personal—Dr Will D Runyon, at present superintendent of the Union Printers' Home at Colorado Springs, and formerly assistant superintendent of the State Sanatorium, Oakdale, has been appointed medical director of the Woodbury County Tuberculosis Hospital——Dr Lena A Beach, Carroll, has been appointed head of the Women s Reformatory Rockwell City——Dr Eugene O Koeneman, Eldora, has been appointed physician to the State Industrial School for Boys

KENTUCKY

Hospital Head Retires—Sister Euphrasia for more than forty years superintendent of St Joseph's Hospital, Lexington retired January 28 and will spend the balance of her life at Nazareth

Personal—Dr John G South, Frankfort, was elected president of the Kentucky State Board of Health January 9, for the fourth consecutive term——Dr H H Carter, Shelbyville, has been appointed a member of the state board of health, succeeding Dr O C Robertson, Middlesboro

MARYLAND

Personal—Word has reached Baltimore of the illness of Dr Howard A. Kelly, who is now at Kissimee, Fla His condition is said not to be alarming——Dr George H Hocking Govans, who was shot several times by a demented patient, is recovering and will leave shortly for New York to recuperate.——Dr Irvin M Wertz, Hagerstown, was severely injured recently when a taxicab in which he was riding collided with a delivery truck.

More Room for Insane Needed—As a result of the failure of the last legislature to provide funds for the erection of buildings at the state hospitals for the care of the insane the City Detention Hospital for the Insane at Bay View will be overfilled by the end of 1917 There are now 268 insane patients at the institution, as compared with 139 a year ago The legislature voted in favor of state care of all indigent insane in Maryland, but the last legislature failed to provide for new buildings

MASSACHUSETTS

Physical Training in Public Schools—A committee of leading educators has been formed to secure adoption of a bill, drafted by Dr Dudley A Sargent, Harvard, providing for physical training without military features in the public schools

MONTANA

Personal—Dr James H Drake, Mondak, has been appointed county physician of Bighorn County, and Dr Wilson A Russell, Hardin, county health officer

Physicians and Surgeons Building Incorporated—Articles of incorporation of the Physicians and Surgeons Building Commission, Butte, have been filed The company has a capital stock of $100,000

Society Condemns Contract and Fraternal Practice—The Missoula County Medical Society has gone on record as condemning fraternal or large contract practice, by its endorsement of a report of the committee appointed on that subject, of which Dr George M Jennings, Missoula, was chairman

NEBRASKA

Personal—Dr J S Anderson, Seward has been reappointed state veterinarian, and Dr W T Pritchard, North Platte, has been appointed deputy state veterinarian ——Dr James D Case, Dorchester, has been reappointed state health inspector of the state board of health, and Dr William F Wild, Lincoln state bacteriologist ——Dr Frank S Owen has been elected president and Dr Ernest T Manning vice president of the Omaha University Club ——Dr William L Ross, Omaha, was painfully injured by the overturning of his automobile, January 10

NEW MEXICO

Resigns Commission—Dr Henry A Ingalls, Roswell has resigned his commission in the Medical Corps of the National Guard, and has resumed practice at Roswell

Visiting Nurse for Schoolchildren—As a result of the cooperation between the medical and dental professions, and the school authorities of Albuquerque, a school and visiting nurse has been employed to secure a better standard of health among schoolchildren

NEW YORK

Birth Control Legislation—A bill designed to legalize the dissemination of knowledge regarding the prevention of conception was introduced into the legislature, January 24, by one of the socialist members of that body

New Long Island Hospital—The Mercy Hospital, a small institution conduced by the French Nursing Sisters at Hempstead, L I, is to enlarge its activities A 97-acre site has been purchased and plans are completed for the erection of a group of hospital buildings to cost $100,000, one of which will be a convalescent home costing $30,000

State Death Rate—The state health department reports that for 1916 the death rate for the state was 14 6 per thousand population With the exception of 1915, when the rate was 14 5, this is the lowest annual death rate recorded in the state The infant mortality rate has been cut from 110 per hundred thousand population in 1906 to 51 2 in 1916 Measles alone of the infectious diseases has shown a slightly higher rate of mortality than in preceding years The mortality rate of typhoid fever fell to 5 8 per hundred thousand as compared with 15 in 1910, and 26 7 in 1900

Personal—Dr John H Pryor has been elected president of the Buffalo Association for the Relief and Control of Tuberculosis ——Dr Edgar R McGuire, Buffalo, has been elected to the chair of surgery in the Medical Department of the University of Buffalo, to fill the vacancy caused by the death of Dr Roswell Park ——Dr Samuel M Strong has been elected chief of the surgical staff of the Flushing Hospital, to succeed Dr C B Story ——Dr Anthony F DeGraffenried Bayside, has been elected secretary of the surgical staff of the hospital, succeeding Dr George J J Lawrence, who is with the troops on the Southern border

Chamber of Commerce Opposes Compulsory Health Insurance—The New York State Chamber of Commerce has put itself on record as opposed to the Mills bill for compulsory health insurance which was introduced into the senate, January 15 The committee held that the expenses of sickness, allowance for medical attendance, etc, should be borne by the employer and employee, in equitable proportions and the state should pay only the expense of supervision The chamber, however, favored the creation of a commission by the legislature which should ascertain whether employees are receiving a living wage and investigate the conditions under which they live

New York City

Polk Portrait Presented to Academy—At a stated meeting of the Academy of Medicine February 1, Dr Walter B James announced that the portrait of Dr William M Polk had been presented to the academy and that this completed the full line of portraits of presidents of the academy Dr George D Stewart made the address of acceptance on behalf of the academy The portrait is the work of Miss Belle Isaacs

Wellington Law in Effect—The Wellington law which went into effect, February 1, provides that children must remain in school until they are 15 years of age or if they wish to go to work before reaching that age, that they must be graduates of elementary schools Under this law the state industrial commission supervises the issuing of permits to children by health officers The 50 000 children to whom permits to work have been issued during the past year are not affected by this law It affects only the children who will seek permits from now on

Personal—Dr Douglas Symmers has been appointed assistant director of the pathologic laboratories of Bellevue and Allied hospitals ——Dr Sigismund S Goldwater has been appointed by the board of estimates, consultant on health and hospitals ——Dr Arthur Freeborn Chase has been elected a member of the board of trustees of Bryn Mawr College ——It is announced that on May 1, Dr John S Billings, deputy commissioner of health, will retire after more than twenty years of service Dr Billings expects to continue his work in preventive medicine as health officer for the stock exchange and public library

Death Rate Still High—The hospitals of this city are overcrowded and this condition is reflected by the mortality statistics For the week ending January 27 there were almost 100 more deaths than during the corresponding week of last year, the rate being 17 34 as against 16 46 for the corresponding week of 1916 As during the preceding weeks, respiratory diseases were largely responsible for the increased morbidity and mortality The contagious diseases scarlet fever, measles and diphtheria are not as prevalent as during previous years The city hospitals for contagious diseases are filled to only 25 per cent of their capacity

Public Health Education in the Movies—The state health department's bureau of education find that free shows do not attract any considerable number of spectators, or arouse as much interest as shows for which admission is charged For these reasons the bureau of public health education has arranged to loan health reels free to moving picture theaters which will show them as a part of their regular program The pictures shown have an introductory legend and a "trailer' indicating that they are shown by the department of health The department requests any one interested in this form of public health education to arrange with their neighborhood moving picture theater for the display of health films

Eating Places Must Have Permits—Because of certain legal difficulties encountered by the department of health in dealing with insanitary and dirty restaurants and hotels, the board of health has enacted an ordinance prohibiting the operation of any restaurant in New York City except under a permit from the board of health The term restaurant in this ordinance includes every buffet, lunch room, grill room, lunch counter and every other place where food is prepared, cooked, served, sold and consumed on the premises and every counter in a saloon where food is given away The permit system will go into effect immediately and will be similar to that used so successfully by the department in the control of the milk supply

Council of State Medical Society Reproved—At the last meeting of the New York County Medical Society a resolution was passed disapproving of the action of the council of the state medical society in endorsing the tentative draft of the compulsory health insurance bill While it was acknowledged that the council of the state society had not transcended its powers in taking this action, it was the prevailing opinion that such action should not have been taken until the county societies had had time to discuss the proposed bill and had expressed an opinion on it At this meeting the proposed medical practice act, which would require annual registration, carrying with it a fee of $2, was also discussed and disapproved It was the consensus of opinion that any help that it might lend in the prosecution of illegal practitioners was more than counterbalanced by the inconvenience it would impose on the members of the profession

PENNSYLVANIA

Academy Purchases Building—The Pittsburgh Academy of Medicine has purchased the property of the Bellefield Club, a lot 50 by 140 feet, with a two-story brick building, for the sum of $2,500

Typhoid in Centre County—Up to February 1, there were reported ninety cases of typhoid fever in the south precinct of Rush Township, Centre County with one death The hospital and private sanatorium of Philipsburg are taking care of as many patients as they can accommodate The fever in nearly every case has been found in the homes supplied with water from one source A warning has been given to boil all water and the reservoir and pipe line are to be given a careful investigation

Personal—Dr John B McAlister, Harrisburg has been elected a trustee of Gettysburg College——Dr George B Kalb, Erie, who has retired from practice and removed to California was recently presented a silver loving cup by the Erie Antituberculosis Society——H Lyndley Hosford, who had been secretary to Commissioner of Health Samuel G Dixon for five years has resigned to resume charge of the campaign of a committee of citizens of New York, proposing the enactment of health laws similar to those of Pennsylvania

Philadelphia

Medical Institutions—An elaborate statement was issued, January 27, by the pneumonia commission of the Department of Health and Charities which is actively continuing its study of the causes and conditions responsible for grip and pneumonia This commission is headed by Dr David Riesman

College Endowment—A reunion supper of more than 100 workers for the endowment fund for the Women's Medical College of Pennsylvania was given, February 2, in the college building The purpose of the meeting was to elect new officers, to obtain a charter, and to get on a permanent working basis so that the fund of $70,000 now on hand can be raised to $1,000,000

License Test Case—John A Seibert, a neuropath, was convicted, January 30, before Judge Martin in Quarter Sessions Court for practicing medicine without a license The prosecution was brought by the State Bureau of Medical Education and Licensure, and was a test case to determine whether neuropaths are compelled to be licensed Sentence was deferred until the disposition of a motion for a new trial should be announced

New Officers—Society of Normal and Pathological Physiology president, Dr Paul A Lewis, vice president, Dr Oliver H P Pepper, secretary, Dr A N Richards, and treasurer, Dr Edward B Krumbhaar——Philadelphia Neurological Society, January 26 president, Dr Williams B Cadwalader, vice presidents Drs Max H Bochroch and Samuel D Ingham, secretary, Dr Samuel Leopold, and treasurer, Dr Nathaniel S Yawger——Philadelphia Genito-Urinary Society president, Dr Hiram R Loux, vice president, Thomas R Neilson, and secretary-treasurer, Benjamin A Thomas——Physicians Motor Club president, Dr S Leon Gans vice presidents Drs John J Robrecht, Charles A E Codman and Charles R Haig, Jr, secretary, Dr Howard A Sutton and treasurer, Dr Lewis H Adler

Legislation for Clean Streets—Legislation giving state officials power to compel Philadelphia street cleaning contractors to clean up the streets and to comply with state regulations is being considered by the legislative committee of the Walnut Street Association The 1917 specifications for street cleaning have not been lived up to by the contractors They are not using water or flushing streets and the block men are not obeying the rules, which specify the carrying of sprinkling pots in front of every dust carrier The widespread epidemic of pneumonia, grip and other disorders is probably caused in some degree by the condition of the streets, and unless they are cleaned up it is feared the toll may be heavy in infantile paralysis victims during the coming summer Since January 1 there have been 752 deaths from pneumonia in Philadelphia, as compared with 675 during the same period in 1916

VERMONT

New Members—The governor has made the following appointments on the State Board of Medical Registration Dr W Scott Nay, Underhill, reappointed for six years, Dr Amos Eugene Parlin, Island Pond, a former member of the board eclectic member, for six years, and Dr Edward Kirkland, Bellows Falls, as homeopathic member, to fill out four years of the unexpired term of Dr E B Whittaker

Personal—Dr William R Rowland, East Corinth, is said to have retired from practice and has entered the universalist ministry He will be in charge of parishes at New Madison, Greenville and Palestine, Ohio——Dr Don D Grout, superintendent of the State Hospital, Waterbury, for twelve years, has resigned, and has been succeeded by Dr Watson L Wasson, assistant superintendent

CANADA

The Ontario Medical Commission—Mr Justice Hodgins resumed the sittings of this commission the past week Lieut-Col Irving H Cameron of the University of Toronto urged that a proper diagnosis could only be made except through a complete knowledge and understanding of the human body, and that massage treatment, such as osteopaths and chiropractors used, was not neglected in the medical courses of the universities

Feebleminded Require Institutions—The annual meeting of the Ontario Society for the Care of the Feebleminded was held in Toronto, February 2 Dr Joseph D Page, superintendent of the Immigration Hospital, Quebec City, spoke on feeblemindedness in relation to immigration, stating that, owing to hasty examinations and lack of specially trained examiners, many mentally defective persons were admitted He advocated the inspection of immigrants before their tickets were bought, and also that Canadians should be employed as ship surgeons Dr Gordon Bates, Toronto, outlined the work of the Toronto branch of the society The city council favored using the Industrial Farm and would ask the legislature for permission to raise the money for the erection of suitable buildings

University Men Overseas—Brown, Toronto 1908 is recovering from enteric fever in St George's Hospital, Bombay, India, Little, Toronto 1914, is on sick leave in India following paratyphoid fever, Maclachlan, Queen's, is in Colaba Hospital, Bombay, recovering from fever, Moon, Toronto, 1914, and Ball, Toronto, 1914 are at the front in Mesopotamia, Roy Philips, Toronto 1914, is with No 23 Indian General Hospital at Basra Mesopotamia, Dr Ramsay, McGill University, is at the front in Mesopotamia, Lyons, Dalhousie University (Halifax, N S), is also in Mesopotamia, Lieut Edward Fidlar, R A M C, is in Bombay——Lieut-Col Ethelbert B Hardy, D S O, Toronto, has been appointed commanding officer of the Toronto Base Military Hospital, succeeding Major Camown A A Warren, who returns to the headquarters staff Military District No 2, Toronto——Capt W L C McBeth, Toronto, is to command the Military Hospital at Hamilton, Ont——Capt J S McCallum winner of the Military Cross, is to be assistant to Captain McBeth

Personal—The Victoria Cross has been awarded to Major Roscoe D Arnott, Stratford, Ont, for conspicuous bravery on the field of action——Lieut-Cols Robert Rennie, Toronto and Edward C Hart, Victoria, B C, C A M C, have been made Companions of the Order of St Michael and St George——Capt John Arthur Cullum, Regina, Sask, C A M C, has been awarded the Bar to the Military Cross for evacuation of the wounded under heavy fire——Major Charles Carter, Hamilton Ont C A M C, has been appointed deputy assistant director of medical services in charge of the troops at Hamilton Brantford, St. Catherines and Niagara Falls, Ont.——Capt Malcolm A Carmichael, Strassburg Station, Sask C A M C, medical officer of the Ninety-Sixth Winnipeg Reserves, has been transferred to the medical training school at Shorncliffe, England——Lieut-Col George Clingan, C A M C, Brandon, Man, has been given command of the Canadian Convalescent Hospital at Monks Horton, England Capt John M Eaton, Winnipeg Man, has been appointed second in command——Dr Charles C Tatham, formerly of Cargill, Ont., has been appointed medical superintendent of the Strathcona Hospital, Edmonton, Alta., which was taken over by the Military Hospitals Commission early in December Dr Hobert L Collins has been appointed to the staff of that hospital——Major W W Judd and Capt C H Hudson have resigned their commissions in the Canadian Army Medical Corps

GENERAL

Missouri Valley Physicians to Meet—The annual meeting of the Medical Society of the Missouri Valley will be held in Keokuk, Iowa, March 22 and 23, under the presidency of Dr Charles R Woodson, St Joseph, Mo The society will be the guests of the Physicians Club of Keokuk

Bequests and Donations—The following bequests and donations have recently been announced

Methodist Hospital Philadelphia, $5,000, by the will of A A Stephens Tyron, Pa

The Appui aux Artistes, Blind French Soldiers Hospital, at Parma, Italy, and the Italian Red Cross equal parts of $13 500, the net proceeds of an operatic entertainment, given in Chicago January 21

Fish Hatchery Discontinued—On the recommendation of the commissioner of fisheries, the secretary of commerce has discontinued the fish hatchery located at Havre de Grace, Md, at the mouth of the Susquehanna River for the propagation of shad (*Commerce Reports* Jan 31, 1917) The legislature of Maryland has neglected to provide legislation protecting this fish so that the take of shad roe has fallen in twenty years from about 210 000,000 maximum to a little over 2 000 000 minimum, increasing the cost of propagating the fish at this station to more than twelve times what it formerly was

FOREIGN

French Physicians Raise Their Fees—The syndicate of physicians of the Seine district have agreed to charge 25 per cent more for their services hereafter for clients who have not had to suffer directly from the fact of the war

New Hospital for Women at Munich—The new Universitats-Frauenklinik was recently dedicated at Munich It is said to be the largest of the kind in Germany The building alone cost 3 000 000 marks about $750,000, and the equipment nearly a third as much Doderlein is the chief of the clinic

Embargo on Medicinal Herbs—The French government by decree of Jan 25, 1917, from and after January 27 prohibits the export, etc of fruits for distilling, and roots, herbs, flowers, leaves barks lichens, fruits and seeds of medicinal character, subject to the usual exceptions (*Commerce Reports,* Jan 31, 1917)

Coffee Grounds as Feed for Cattle—A company in Berlin is collecting coffee grounds, and especially the grounds from the various cereal substitutes for coffee and is drying them to use as feed for cattle An official appeal is made to restaurant keepers and others to save and collect the grounds for this purpose

Chair for Welfare Work Founded at the Collège de France, Paris—The city and county authorities of Paris have founded and appropriated funds for a chair of *prevoyance et assistance sociales* at the College de France of the University of Paris The incumbent of the chair has not been selected as yet The salary is to be 12,000 francs, about $2,400

Homage to Gersuny—On the occasion of the fiftieth anniversary of R Gersuny's entering on the practice of his profession, an endowment fund was presented in his name to the training school for nurses connected with the Rudolfinerhaus at Vienna which he was mainly instrumental in founding The fund is for welfare work among the nurses

Institute for Research on Psychiatry—A number of members of the Kaiser Wilhelm Association have planned a German institute for research on psychiatry The funds subscribed as yet do not permit an independent establishment, but it is proposed to organize an institute of the kind as a branch of the Munich psychiatric clinic, after the close of the war

"Treatment of Hernia Without an Operation"—The military authorities in the Berlin district have closed the Colemann establishments at Berlin Colemann is said to be of English birth and advertised to cure hernia without operative measures, working under his own name and as the Dr Colemann's Bandagengesellschaft m b H He had been several times reprimanded by the Berlin Tribunal of Honor, but now the military authorities have put him out of business

The Kraussianum at Munich—Nearly $400 000 was bequeathed in 1910 to the city of Munich by Dr G Krauss to found, as a memorial to his father, an institution for mechanical and other forms of orthopedics, especially those practiced by the elder Krauss The stately building housing it is now completed It stands on the grounds of the University orthopedic clinic with which it is closely affiliated, Prof F Lange being in charge

Deaths in the Profession Abroad—A Chauveau, the biologist and physiologist, at Paris, aged 89——Huguet Pike, an American doctor at Paris, admitted to practice in France in 1869, chevalier of the Legion d'honneur——The former professor of ophthalmology at the Universities of Bern and Rostock, von Zehender, aged 91——C Posselt, professor of diseases of the skin and syphilis, at the University of Munich, aged 79——E Leser, professor of surgery at the University of Halle until 1894, since then he has been living at Frankfurt a M——H Schule, director of the insane asylum at Illenau and coeditor of the *Allgemeine Zeitschrift fur Psychiatrie*, aged 76——W Lublinski, author of numerous works on his specialty, laryngology, aged 64

Centennial of Father of Atomic Notation, Isolator of Several Familiar Drugs—The Chemical Society of France held a memorial meeting, December 9, on the hundredth anniversary of the birth of the French chemist, C F Gerhardt, 1816-1856 His fame rests mainly on his conception of the molecule as a unitary structure, built of atoms, as the basis of all substances Among the chemicals he isolated are said to be acetanilid, acetylsalicylic acid and cinnamic acid With Laurent he founded a school of practical chemistry at Paris the aim of which was to "teach the art of the laboratory to students entering a scientific, medical or pharmaceutic career or industrial chemistry" The school was not commercially a success, and Gerhardt's life was a struggle, sacrificing his position, his fortune and even his life, to the search for truth, dying at 40 He was professor at the University of Strasburg the last year or two of his life

WAR NOTES

Losses in the Profession in Germany—The *Deutsche medizinische Wochenschrift* of Dec 14 1916 gives the number of physicians who have fallen at the front as 395, 214 have died from sickness contracted in the course of their service with the troops, 221 have been severely wounded, and 677 wounded but not severely, while 200 have been taken prisoners and 110 are missing These figures are from the German casualty lists 1 to 700

Virchow's Medals Donated to the Common Cause—Rudolf Virchow's family have donated to the Berlin Goldsammelstelle seven gold medals that had been conferred on the scientist by foreign scientific organizations The medals have a total weight of 1,200 gm and are valued at 2,800 marks in gold, about $650 The heirs of Mommsen have taken a similar step, turning in to the gold reserve the medals that had been awarded to Mommsen in his day

The Interned Sick and Wounded in Switzerland—The *Munchener medizinische Wochenschrift* states that fully 30 000 sick and wounded are now interned in Switzerland and being cared for there This, it adds, is a most comprehensive practical philanthropy which insures the permanent gratitude of all the countries involved There have been 128 cases of insubordination compelling disciplinary measures and twelve of the interned had to be returned to the prison camps whence they came

Effect of War Diet on the Sick—The local sickness insurance societies of Berlin have recently sent out question blanks to the physicians connected with the work to inquire as to the effect of the war diet on different categories of the sick, whether it has a depressing influence on the resisting powers or not Separate reports are asked for those under and over 18, and for men and boys and women and girls Special data are also sought as to the influence of the war diet on the anemic, the nervous, the tuberculous, those with stomach trouble, with acute diseases, and the pregnant

Vacation in Norway for Nurses with the Belligerent Forces—Our German exchanges mention that at the recent annual gathering of the hotel proprietors of Norway, a suggestion was made by the chief of the medical department of the Norwegian army to the effect that the hotel proprietors offer the nurses at the hospitals of the belligerent forces free accommodations to enable them to get a brief rest and respite The plan was cordially taken up and backed by private individuals, and invitations for the purpose have been sent to the headquarters of the forces of each of the belligerent nations An equal number of nurses from each of the forces is planned

Conference to Study Welfare Work for War Cripples—A conference for the study of professional retraining and of other questions affecting the wounded in war is to be held by representatives of the Allies at Paris, March 6, under the initiative of the Belgian government The organizers of the conference are appealing to all experts in any of the questions relating to this subject to report to the secretary, rue du Bocage de Bleville, Havre, or the Office National des Mutiles et Reformes de la Guerre, 97 quai d'Orsay, Paris The five sections are devoted to the physical and the professional training, the placing of the men, and their economic and social interests

Typhus and Smallpox in Poland—The *Berliner klinische Wochenschrift* gives the figures for the incidence of these diseases in the newly acquired portion of Poland, now called the Generalgouvernement Warschau since the occupation by the Germans By three-month periods there have been 704, 5,256, 6 294, and 2,309 cases of typhus, with, respectively, 32, 428, 510, and 140 deaths The corresponding figures for smallpox are 955, 1,029, 918, and 195, with 157, 144, 130 and 23 deaths The figures show that the health authorities are getting the diseases under control, and that smallpox will soon be practically stamped out, while typhus is also declining There have been no cases of cholera in the district for more than a year

The New Law for Patriotic Service in Prussia—Conferences are being held by the university authorities medical societies and groups of all kinds of organizations to discuss ways and means for carrying into effect the provisions of the law for auxiliary patriotic service, *vaterlandische Hilfsdienst* The law went into effect, Dec 5, 1916 and mobilizes the entire population between the ages of 16 and 60, not directly engaged in the war The government authorities and the representatives of the organized physicians have been in prolonged and confidential conference over the working of the law as it affects medical men and medical students The outcome has not been made public as yet.

BERLIN LETTER

(*Received Jan 26 1917*)

Berlin, Dec 4, 1916

Personal

Nov 12, 1916, Professor Bruns, the neurologist, died in Hanover at the age of 58 He had been one of the pupils of Professor Hitzig of Halle His best known published work is the section on tumors of the nervous system in Nothnagel's Special Pathology and Therapy" His contribution to the subject of hysteria in children is also well known His last work of any great size was the 'Handbook on Diseases of the Nervous System of Children" in which he was a collaborator of Ziehen and Cramer He also made many individual contributions to the diseases of the spinal cord tumors of the brain and their treatment, the neuritides of diabetes mellitus, etc

Prof E Gaupp ordinarius in anatomy in Breslau died suddenly, Nov 24 1916 He had succeeded Professor Hasse in this position at the beginning of the present semester

Health of the German Army

A recently published report of a member of the medical division of the army details the morbidity of the troops from the beginning of the war to February, 1916 The figures are made on the basis of a thousand The average monthly morbidity from August, 1914, to January, 1915, was 129 3 from February to July 1915, it was 114 2, from August, 1915, to January, 1916 it was 105 The morbidity rate has not increased since then Particularly noteworthy is the absence of any epidemics The results of the surgical treatment given in the various hospitals were exceptionally good The results are given in percentages, as follows 86 6 per cent recoveries in the field military hospital, and 90 1 per cent in the home hospitals, only 1 5 per cent. of the wounded and sick died. These percentages could have been obtained only by having efficient medical care and a well trained corps of nurses At about the middle of 1916 18,000 physicians were in the field, and 6 000 were attached to the military service at home Four thousand served as volunteer nurses The medical service was aided by 92,000 members of the sanitary division and army nurses 23 000 male and female nurses in the military districts and 72,000 in the home hospitals Nervous diseases occurred less frequently in the troops in active service at the front than among those not so engaged Diseases due to exposure occurred much less frequently than one would suppose The supply of drugs is more than sufficient It is ample to permit of furnishing drugs to the armies of all the central powers The recently adopted steel helmet has proved to be of great value. Without any forehead protection it wards off shrapnel bullets, pieces of shell and other larger explosives, and with the forehead protection it even wards off rifle shots

NEUROSIS AND NATIONALITY

In a recent number of the *Wiener klinische Wochenschrift*, Dr Schneider discussed the predisposition of various nationalities to diseases of the nervous system, basing his remarks on observations made on Austro-Hungarian soldiers He found that the Magyars the Roumanians and the Czechs were particularly predisposed to severe nervous disturbances as the result of their war experience The Poles and German-Austrians occupy the middle ground, whereas the Jew shows a strong predisposition to these diseases From the literature the impression is gained that nationality and race play a considerable role in the etiology of functional nervous disturbances, especially of the hysterical type While Schneider's observations confirm these impressions, the result was not quite what the literature would lead one to expect The Poles, for instance, show a predisposition to severe nervous disturbances of all kinds However, the percentage of persons so affected corresponds with the average of all nations (about 12 per cent) All the remaining Slavs, excepting the Czechs, show a much lower percentage A proper conception of the percentages given by Schneider can be gained by considering only those nationalities which were represented by more than 100 patients These were the German-Austrians the Czechs and the Magyars The Poles were represented by eighty-one cases, too few to permit of drawing definite conclusions All disturbances of the nervous system occurring among the first three nationalities mentioned above were as follows Among 377 Germans there were thirty-three cases (9 per cent), among 194 Czechs there were thirty cases (15 per cent) and among 199 Magyars there were thirteen cases (6 5 per cent) There were seven cases of ambulatory war neuroses, all occurring among the Czechs who, on the whole seem to be particularly predisposed to traumatic hysteria About 40 per cent of the Jews had nervous disturbances, mostly mild in type, with complete recovery and rarely exhibiting hysterical symptoms Of the Roumanians 21 per cent were affected, and of the Germans only 13 per cent, of the Ruthenians and southern Slavs, 11 per cent A strong predisposition to the apathetic depressive nervous diseases was noted among the Roumanian soldiers, such cases occurring even when the troops were on the march

Campaign Against Venereal Diseases

The Prussian medical commission has formulated the following rules of governing the campaign against venereal diseases 1 General rules for combating venereal diseases (*a*) improving the economic status of the population so as to make early marriage possible, and to guard the female population against delinquency, improving housing conditions and instituting official supervision of homes (*b*) instituting instruction on sexual life and especially on the dangers of extramarital sexual relationship and of sexual diseases, (*c*) improving the physical and moral status of youth by means of gymnastics, play and sport, (*d*) instituting a campaign against the misuse of alcohol, (*e*) improving the diagnosis and treatment and preventing the spread of venereal diseases (*f*) improving the means and methods for treating venereal diseases, erecting dispensaries in which such diseases can be treated, with the assurance of absolute secrecy as to the identity of the individual and treating all severe cases in an institution, (*g*) proper instruction by the physician as to the dangers of venereal diseases, their method of spread and especially the precautions which must be taken by one who is under treatment, (*h*) reducing the price of the newer specific drugs, and (*i*) campaign against quackery 2 An amendment of Paragraph 180 of the imperial crime punishment regulations is urged 3 Supervision of prostitution, the burden of which shall hereafter fall on the medical man and not on the police 4 Enforcement of the law of Oct 28, 1905 and the ministerial edict of Dec. 11 1907 5 Keeping the prostitutes off the streets and out of public places, and segregating them for moral as well as police reasons

LONDON LETTER

London, Jan 15, 1917

The War

NEW FOOD REGULATIONS

Lord Devonport, the food controller, has issued six orders regulating the use of bread, sugar and other staple foods It is the duty of the food controller to regulate the supply and consumption of food in such manner as he thinks best for maintaining a proper supply of food, and to take such steps as he thinks best for encouraging the production of food The first of the orders makes an important extension of the two existing flour and bread orders, under which millers are now required to extract from wheat a percentage of flour averaging 76 (as stated in a previous letter to The Journal) Under the new order, every miller will be required to add to the prescribed percentage a further percentage of not less than 5, either by a further milling of wheat or by the addition, at his option, of flour derived from barley, maize, rice or oats He may add yet another voluntary 5 per cent (making 10 per cent in all) in addition to the compulsory 5 per cent With regard to the milling of grain other than wheat, it is stated that barley and rye present no difficulties Existing machinery, however, will not mill maize or oats at the same time as it mills wheat, and the admixture of maize or oats with wheat will probably have to be made in the form of flour A wheat (restriction) order prohibits the use of wheat for any purpose except that of seed or of making flour, and thus makes illegal the feeding of wheat to animals The object is, of course, to reserve wheat for human consumption A good deal at present is being dissipated in other directions, particularly in the feeding of stock, and it is necessary to check this waste An exception is made to the order in respect of "tailings, screenings and damaged wheat unsalable for milling" The food controller now prohibits entirely the use of any grains required for food or feeding-stuffs, or any of their products, for the purpose of food for game birds It is felt that with the present emergency the rearing of pheasants and indulgences of this kind cannot be continued The manufacture of extravagant sweets is stopped A maximum retail price of 6 cents an ounce for chocolates and 4 cents an ounce for other sweetmeats is fixed The price in each case includes the price of any covering in which the sweets are sold The use of sugar or chocolate for the external covering of cakes, pastry or similar articles is prohibited During 1917 no manufacturer will be allowed to use for sugar confectionery or chocolate more than 50 per cent of the amount so used by him in 1915 The use of winter milk in the manufacture of chocolate is prohibited The export of oats from Ireland is prohibited except under license The price to be paid to growers for potatoes is $40 a ton for the first quality in January and February, with a rising scale attaining a maximum of $45 for later months The maximum price for the best seed potatoes is to be $60 a ton

ACCUMULATED FATIGUE IN WARFARE

The second interim report of the British association committee, of which Prof J H Muirhead is chairman, to investigate fatigue from the economic standpoint contains an interesting section by Dr T G Maitland on accumulated fatigue in warfare The breakdown resulting from long-continued trench strain, while soon recovered from after a period of rest, leaves the quality of the soldier's work on his return to activity impaired, his aim is less good, his decision less prompt The hope of obtaining an ideal working day for each unit is incapable of realization, as the strain in the field varies with the occasion and depends on such mutable factors as sleep, food, noise and nervous strain With the present greater ability to supply reinforcements, strain can be diminished as well as the actual fighting units more often replaced, and in this way an opportunity is given for what Dr Maitland calls a "growing delicacy of perception in the anticipation of the breaking point" From a military standpoint the most important item is the large class of combatants who do not collapse in the field but return from the lines with extreme pallor, a low blood pressure, and a *faiblesse irritable* shown by the restlessness of hands and feet In these cases fatigue has gone slightly beyond the possibility of sound physiologic recuperation To reduce the incidence of such cases, which are an encumbrance, the hours in the fighting line have been lately diminished The ultimate sequel of such long-continued fighting strain has been seen by Dr Maitland in Serbian soldiers who have lived through six years of nearly continuous Balkan War and many of whom show marked arteriosclerosis He was able in most cases to exclude the action of mineral poisons, alcohol and acute specific toxins, and to establish the production of fibrosis in the arteries from hard work alone

Another Death from a Salvarsan Substitute

Some weeks ago in describing a death due to kharsivan (The Journal, Sept 30 1916, p 1030) I stated that the coroner of southeastern London, who held the inquest, said that he had had in his district three deaths from salvarsan or its substitutes within a short period After a brief interval the following case, again in the same district, has occurred at Guy's Hospital A man, aged 33, a tram conductor, was admitted with syphilitic meningitis of the spinal cord He was given an intravenous injection of arsenobenzol, the French substitute for salvarsan He had been carefully prepared and the operation lasted three quarters of an hour A rather small dose, 0 04 gm, was injected intravenously, and the patient died suddenly two hours later Dr Spilsbury, pathologist, who made a postmortem examination, said he found a large tumor in the front part of the brain, and extensive softening of the brain Death was due to coma from disease of the brain, accelerated by the administration of arsenobenzol The patient was really in a very serious condition, but the exact nature and extent of the disease of the brain could not be easily diagnosed The dose of arsenobenzol given was the usual dose, but, if anything rather small The witness was afraid there was a danger of fatal results occasionally, but more often when there was disease of the brain He thought every care was exercised in the administration of the drug, which was one of the best known remedies It was similar to kharsivan, the English substitute, and was being used with most beneficial results in a large proportion of cases The jury returned a verdict of death by misadventure

The War and Public Health

In his report for 1915-1916, Dr Arthur Newsholme, health officer of the Local Government Board, states that the war has directed attention to means for improving the health of mothers and of their children during the first five years of life During 1915, work with this object was largely augmented The need for greater effort to save child life is shown by the markedly lower natural increase of population in 1915 than in 1914 In the former year there were 362,354 more births than deaths in England and Wales Last year this excess of births over deaths was only 252,201 There were 64,569 fewer births and 45,584 more deaths in 1915 than in 1914 In 1915 as many as 98,477 infants died in their first year after birth, and 55,607 died at ages of from 1 to 5 Dr Newsholme says that there is no insuperable difficulty in reducing the total deaths in childhood to half the present number At the end of last March about 1,000 health visitors had been appointed by local authorities This means one health visitor approximately to 800 births annually A steady approach is being made to the standard of one health visitor to 500 births, which was laid down as desirable in his memorandum of November, 1915 So far as infectious diseases are concerned, with the single exception of measles, the record of 1915, like that of 1914, remained favorable Smallpox heretofore has failed to gain more than a temporary footing in any district Dysentery, notwithstanding the return to this country of many soldiers recovering from this contagious and relapsing disease, has not spread In both the civil and the military population typhus has failed to spread, and the amount of typhoid fever has been so small as to inspire fresh hope that this disease, like typhus, will soon be counted among the almost extinct diseases of this country There have been no cases of plague or cholera Cerebrospinal fever showed much activity, and special work was undertaken, both military and civil, to control its spread and to investigate its natural history Acute anterior poliomyelitis occurred sporadically in this country during 1915 Tuberculosis work has been greatly restricted by the war

Reference is made to the national scheme for the diagnosis and treatment of venereal diseases, which promises to be among the most successful public health work of the early future As the nonrecommendation of compulsory notification by the royal commission has been criticized, Dr Newsholme recalls that in the memorandum which he presented to that body he emphasizes the following considerations, to which further inquiries have led him to attach increased importance Even if compulsory notification of these diseases could be enforced—a very doubtful point—the consideration of its enforcement should be postponed until after these conditions have been fulfilled (*a*) Adequate arrangements must be available for the gratuitous treatment of all applicants suffering from venereal diseases in every administrative area (*b*) There must be legal prohibition of treatment by unqualified persons so that all cases of early venereal disease receiving treatment will come under the observation of physicians When these conditions have been fulfilled, patients will generally avail themselves of the facilities for treatment officially provided or will be treated by their own physician, and the question may legitimately arise whether the public safety is then adequately protected, or whether notification is necessary to insure that every patient continues treatment as long as this is needed in the public interest Attempts to secure the notification of venereal disease in adults under any of the forms in which it has been recently suggested would only diminish recourse to the treatment shortly to be provided in all our chief centers of population

The heavy demands of the army for physicians has led to an extensive employment of women as health officers, assistant health officers, tuberculosis officers and resident medical officers in sanatoriums and fever hospitals In this great national emergency their services have proved invaluable

Selected Parents

A paper on "The Principle of Eugenics" was read to the Insurance Institute of London by Major Darwin son of Charles Darwin and president of the Eugenics Education Society Major Darwin compared the inborn qualities of a man to be a fixed anchor to which he is tied by an elastic cord Everything that is possible should be done for the environment of the living—that is, in order to stretch these elastic cords, but it is foolish not to try to insure that the anchors of our successors on earth shall be cast on better ground This is the aim of the eugenist, and, as this science is in its infancy, it cannot be expected yet to have accomplished great things Few persons really care what happens to the nation long after they are dead, yet we must make an effort to insure that the innate qualities of our race shall continue to improve The eugenist aims at substituting for the apparently blind selection of nature in the matter of parentage a conscious and rational selection

The fact that offspring often differ from their parents is frequently held to tell against all eugenic reform, but modern science endorses the belief of every breeder of animals in the advantages of breeding only from the best stock In regard to the methods of the stock yard, it must, however, be remembered that in the case of man his religion must be taken into account, whereas in the case of animals it need not. It is the lessons and not the methods of the stock yard which must be held in view Another objection raised against all eugenic reform is the difficulty of deciding who had better and who had better not become a parent, but if attention be confined to the unquestionably fit and unfit there will be ample work to do As to increasing the birth rate among the fit we must rely largely on awakening the moral sense of our fellow countrymen and appealing to their spirit of patriotism It is immoral and unpatriotic to limit the size of the family when both parents are fairly healthy, except to insure that there shall be an adequate interval between births, and that the family shall be brought up in comfort, but not in luxury, without external aid Reforms in taxation might aid and reinforce this moral precept As to diminishing the fertility of the unfit, the mental deficiency act, if properly administered, would be an example of what might be done, and somewhat similar measures are possible with regard to criminals, drunkards and paupers What is mainly desirable is an investigation to ascertain if the danger to the nation from the present rapid multiplication of inferior stocks is as great as it appears to eugenists If it be so, it must be dealt with with a fearless hand But that is not yet If the nation could see that its future is largely in its own hands, the battle would be half won It is not the creation of the superman which eugenists are now aiming at, for that ideal receives but little support from science The endeavor should be to increase the proportion of the existing higher types, and it is now doubly necessary thus to act in view of the slaughter of our fittest in battle

PARIS LETTER

PARIS, Jan 11, 1917

Death of Professor Chauveau

French science has just suffered a great loss in the death of Prof Jean Baptiste Auguste Chauveau, aged 89 years He was born, Nov 23, 1827, at Villeneuve-la-Guyard (department of Yonne) Chauveau entered l Ecole veterinaire d'Alfort at 17, leaving it at 20 to become chef de service at l'Ecole veterinaire de Lyon A considerable part of his professional life was spent there, first as professor of anatomy and physiology, then as director, to which position he was appointed in 1875 Two years later, i e, at the age of 50, he secured his degree of doctor of medicine Afterward he occupied the chair of general pathology at the Museum of Natural History of Paris, he also was general inspector of veterinary services

It was as a physiologist that Chauveau became known In collaboration with Marey, he invented and put into practical use the method of registration of physiologic movements and especially that of the cardiac rhythm In pathology, tuberculosis was one of the subjects of chief interest to him He was the founder and director of the *Revue de la Tuberculose* He also directed the *Journal de Physiologie et de Pathologie Générales* A member of l'Academie des Sciences since 1886, Chauveau entered l'Academie de Medecine in 1891 and became its president in 1913

The War

MEDICAL EXAMINATION OF CANDIDATES FOR MILITARY AERONAUTIC SERVICE

By reason of the disadvantages presented by candidatures for this service not justified by sufficient physical aptitude, the undersecretary of state of the military health service has warned physicians in charge of the aviation depots to comply rigorously in the examinations with instructions concerning the physical aptitude of the aviator who is to enter the service Moreover, on the arrival of officers at the aviation school, or of soldier aviators at the aviation depots, they must undergo examinations by two physicians At the second examination, which shall be thorough, the attention of the specialists shall be drawn particularly to the necessity of ascertaining the absolute integrity of the respiratory, circulatory and renal functions Careful attention shall be given to discerning organic from inorganic cardiac murmurs Aspirants who present arrhythmia or permanently slow pulse (Stokes-Adams syndrome), tachycardia, Basedowan tachycardia, or extrasystolic arrhythmia will be excluded from service only when connected with an organic lesion of the heart. By way of compensation, the following disorders of cardiac rhythm will not constitute contraindications, when applications are made for positions as student pilots total bradycardia, emotive tachycardia tachycardia due to physical exercise or respiratory arrhythmia All cases presenting emotivity with nervous instability, however, shall be excluded Physicians are to study the health of the students in training by means of repeated examinations, and they are especially urged to study the arterial pressure of the aviators with the sphygmomanometer This practice may be of much value in the course of training, as well as in obviating the dangers of overtraining In a general way, aviation tends to produce a lowering of the highest arterial pressure even when the minimum pressure remains normal, as when the aviator is not in flight This lowering of pressure is especially appreciable in subjects little or moderately trained Overtraining may cause a marked lowering of pressure even in aviators inured to the service

LARGE ABDOMENS (PAUNCHES) AMONG THE SOLDIERS

Drs Desire Denecheau and Henri Mattrais have observed disorders characterized by enormous abdomens without any trace of organic trouble save a slight colitis readily relieved by simple flexion of the thighs The origin of this disorder is traced back to a peculiar action of the diaphragm noticed in patients thus affected It appears like a phenomenon of the motor order which can be produced, as well as relieved, at will In the estimation of Denecheau and Mattrais it is brought about by digestive troubles common in colitis, aerophagia also contributes to the condition, although it is not believed to be the only cause Briefly, this trouble is analogous to the nervous abdomen frequently observed in those whose nerves are overwrought by fright It should not, however, be the cause of discharge from duty, much less, invalidation at half pay

---

Marriages

BERNARD SAMUEL STRAIT, M D, Penn Yan, N Y, to **BARBARA FANNIE KUNTZ**, M D, of South Williamsport, Pa, January 15

GEORGE LOUIS STEELE, M D, West Springfield, Mass, to Miss Vera Gertrude Colburn of Bangor, Me, Nov 30, 1916

PAUL THEODOSIUS FERRER, M D, to Miss Minnie Elizabeth Hoehl, both of Port Chester, N Y, Dec 31, 1916

PAUL E BETHARDS M D, to Miss Florence Freeman, both of Toledo, Ohio, at Brockton, Mass, January 17

CLAUDE GRIFFIN, M D, to Miss Caroline Claire Stewart, both of Carrollton, Ga, Dec 23, 1916

GEORGE CERIO M D, Rome, Italy, to Miss Mabel Norman of Newport, R I, January 20

Deaths

Henry Theodore Bahnson, M D, Winston-Salem, N C, University of Pennsylvania, Philadelphia, 1867, aged 71, a Fellow of the American Medical Association, a Confederate veteran, local surgeon of the Southern Railway System, president of the board of surgeons, chief surgeon of the Winston-Salem Southbound Railway Company, once president of the Medical Society of the State of North Carolina, a member of the American Public Health Association, president of the state board of health, secretary of the state board of medical examiners, a member of the board of directors of the Morganton State Hospital, died at his home, January 16, from angina pectoris

Pearce Kintzing, M D, Baltimore, University of Pennsylvania, Philadelphia, 1887, aged 55, a Fellow of the American Medical Association, chief physician to the Franklin Square Hospital, Baltimore, professor of anatomy and surgery in the Women's Medical College, Baltimore, from 1890 to 1897, professor of practice of medicine and diseases of the heart, and clinical medicine in Maryland Medical College from 1899 to 1901, and since 1904 a director and trustee of the Maryland Medical College, died at his home in Baltimore, about January 31

Frank Sidney Fielder, M D, New York, College of Physicians and Surgeons in the City of New York, 1892, aged 50, a Fellow of the American Medical Association and New York Academy of Medicine, demonstrator of anatomy in Cornell University Medical Department, attending pediatrist to Bellevue Hospital, outpatient department, assistant surgeon United States Navy, during the Spanish-American War, author of several textbooks on diseases of children, died at his home, January 24, from pneumonia

Dexter Boylston Farnsworth, M D, Springfield, Mo, Rush Medical College, 1877, aged 67, formerly a Fellow of the American Medical Association, a member of the Missouri State Medical Association, a specialist on diseases of the eye, ear, nose and throat, died at his home, January 22 At a special meeting of the Greene County Medical Society January 23, it was decided to postpone the annual banquet of the association on account of the death of Dr Farnsworth

Francis A Smith, M D, Rock Island, Ill, Pulte Medical College, Cincinnati, 1891, aged 64, formerly of Zanesville, Ohio, local surgeon for the Baltimore and Ohio Railroad and a member of the Zanesville Board of Education, for six years head physician for Ohio of the Modern Woodmen of America, and since 1903 chairman of the board of supreme medical directors of that organization, died at his home, January 21, from cerebral hemorrhage

James R Barnett, M D, Neenah, Wis, Rush Medical College, 1868, aged 74, a Fellow of the American Medical Association, and at one time president of the State Medical Society of Wisconsin, for four years a member of the state legislature, a veteran of the Civil War, supreme medical examiner of the Equitable Fraternal Union, died at his home, January 30, from senile debility

William A Young, M D., Newport, Ky, Medical College of Ohio Cincinnati 1893, aged 46, formerly a member of the Kentucky State Medical Association, local surgeon for the Chicago, New Orleans and Texas Pacific Railroad, surgeon to the Speer's Memorial Hospital, Dayon, Ky, health officer of Campbell County for eight years, died in the Speer's Memorial Hospital, December 21, from multiple sclerosis

Frederick W Schmidt, M D, Riverdale, Chicago, Northwestern University Medical School, 1885, aged 55, formerly a Fellow of the American Medical Association and a member of the American Association of Railway Surgeons, local surgeon for the Illinois Central System, died at his home, January 31, from septicemia, after an illness of one year

Thomas Jackson Thompson, M D, San Diego, Calif, College of Physicians and Surgeons in the City of New York, 1872, aged 73, for seven years deputy health officer of the port of New York, and later for eight years an officer of the U S Public Health Service in Japan, died at his home in Kensington Park, San Diego, January 10

Jacob S Newcomer, M D, Chicago, College of Physicians and Surgeons Chicago, 1893, aged 54, for many years a practitioner of South Dakota and an officer of the United States Indian Service, senior consulting physician of the Contagious Diseases Hospital of Chicago, died at his home, January 27, from nephritis

Melanchthon C Porter, M D, Topeka, Kan, College of Physicians and Surgeons, Chicago, 1890, aged 54, a Fellow of the American Medical Association, professor of surgery in the University of Kansas, formerly surgeon to the Union Pacific Railway, and health officer of Clay Center, died at his home, January 30

William H Winterbotham, M D, Salina, Kan, College of Physicians and Surgeons, Keokuk, Iowa, 1872, College of Physicians and Surgeons, Chicago, 1884, aged 70, formerly a Fellow of the American Medical Association, a member of the Kansas Medical Society, died at his home, January 21, from influenza

George Wilbur Crawhall, M D, Seattle, Rush Medical College, 1890, University of Pennsylvania, Philadelphia, 1896, aged 54, formerly a Fellow of the American Medical Association, a member of the Washington State Medical Association, died at his home, January 8, from myocarditis

Benjamin F Farley, M D, York, Neb, Rush Medical College, 1870, aged 73, formerly a Fellow of the American Medical Association, and once vice president of the Nebraska State Medical Association, a veteran of the Civil War, died at his home, January 17, from pneumonia

Matthew O Ricketts, M D, St Joseph, Mo, University of Nebraska, Omaha, 1884, aged 60, a colored practitioner of St Joseph, a member of the Nebraska State Legislature from 1893 to 1895, died in St Joseph's Hospital, St Joseph, January 15, from disease of the intestines

Frank Beegle Statler, M D, Johnstown, Pa, Jefferson Medical College, 1889, aged 52, a Fellow of the American Medical Association, died in the Memorial Hospital, Johnstown, January 16, from abscess of the liver, ten days after an operation for appendicitis and cholecystotomy

Arthur Alonzo Vibbard, M D, Albany, N Y, New York Homeopathic Medical College, New York, 1894, aged 48, a member of the Medical Society of the State of New York, a specialist on diseases of the eye, ear and nose, died at his home, January 19, from pneumonia

Horace B Erb, M D, Allentown, Pa, Medico-Chirurgical College of Philadelphia 1888, aged 58, a member of the Medical Society of the State of Pennsylvania, a specialist in diseases of the eye, ear, nose and throat, died at his home, January 24, from pneumonia

Albert W Sharp, M D, Kettle, Ky, University of Louisville, Ky, 1888, aged 59, a member of the Kentucky State Medical Association, a member of the legislature from the Adair-Cumberland District in 1914, died at his home, about January 2, from pneumonia

Leon L Moye, M D, Vidalia Ga, Atlanta (Ga) College of Physicians and Surgeons, 1902, aged 38, a member of the Medical Association of Georgia, formerly a member of the faculty of the Atlanta School of Medicine, died at San Antonio, Texas, January 14

Stacy B Collins, M D, Seaford, Del, Jefferson Medical College 1876, aged 81, a member of the board of education and president of the board of health of Seaford, at one time a member of the state board of health, died at his home January 17, from paralysis

William Henry McLaughlin, M D, Hedrick Iowa, State University of Iowa, Iowa City, 1887, aged 53, formerly a Fellow of the American Medical Association, formerly a practitioner and druggist of Wester, Iowa, died at Springdale, Ark, January 13

Sidney Smith Pruitt, M D, Holland, Ky, University of Tennessee, Nashville, 1886 Barnes Medical College, St. Louis, 1899, aged 55, formerly a member of the Kentucky State Medical Association, died at his home, January 10, from pneumonia

Peter Alois Pfeffer, M D, St Louis, Barnes Medical College, St Louis, 1908, aged 40, formerly a member of the Missouri State Medical Association, died in St Anthony's Hospital, St Louis, January 4, from septicemia, due to the bite of a dog

Frederick Pollock Lane, M D, New Haven, Conn, Yale University, New Haven 1904, aged 36, a Fellow of the American Medical Association, a member of the staff of the Hospital of St. Raphael, died at his home, January 14, from pneumonia

Samuel J Covert, M D, Perrysville, Ohio, College of Physicians and Surgeons, Baltimore 1882, aged 65, formerly a member of the Ohio State Medical Association, died at his home, November 8, from cerebral hemorrhage

John M Cooke, M D, Colorado Springs, Colo, Rush Medical College, 1887, aged 63, a Fellow of the American Medical Association, died at his home, January 14, from cardiorenal disease

Arvid Anderson, M D, New Britain, Conn, University of Michigan, Ann Arbor, 1892, aged 54, a Fellow of the American Medical Association, died at his home, January 10, from pneumonia

Otto Appley, M D, Damascus, Pa, University of Buffalo, N Y, 1880, aged 65, died in the Deer Park Sanitarium, Port Jervis, N Y, recently, after an operation for disease of the intestines

Jacob Bell Cornell, M D, Somerville, N J, College of Physicians and Surgeons in the City of New York, 1878, aged 65, died at his home, January 20, from cerebral hemorrhage

S R Wakefield, M D, Eugene, Ore, Willoughby (Ohio) Medical College 1846 aged 95, died at the home of his son in Creswell, Ore, December 13 from senile debility

Augustus W Harrington, Esther La (license, Louisiana), aged 76, formerly a druggist and practitioner of New Orleans and Rayne, La, died at his home, December 31

Wilfred Cumbermede Hummell, M D, Marysville, Ida, State University of Iowa, Iowa City, 1895, aged 44, died at his home, December 3, from heart disease

Herman F Klemp, M D, Topeka, Kan, Hahnemann Medical College, Chicago 1867, aged 79, died in a hospital in Topeka, January 16, from senile debility

George Carleton Hale, M D, New Bedford, Mass, Vermont Medical College, Rutland, 1891, aged 74, died at the home of his son in Providence, January 13

James Amos Fechtig, M D, Baltimore, Hahnemann Medical College, Philadelphia, 1871, aged 68, died at his home, January 18, from pneumonia

William Daniel Turvill, M D, Madison, Wis, Rush Medical College, 1882, aged 63, died at his home, October 15, from cerebral hemorrhage

Walter John Colgan, M D, Bridgeport, Conn, University of Georgetown, Washington, D C, 1913, aged 27, died at his home, December 1

Relief B Leeds Harding, M D, Long Beach, Calif, University of Michigan, Ann Arbor, 1884, died at her home, December 13

Achibald Mitchell Galbraith, M D, Hayward, Calif, Cooper Medical College, San Francisco, 1889, died at his home, December 30

John O Aldrich, M D, Bath, N Y, Eclectic Medical Institute, Cincinnati, 1883, aged 68, died at his home, January 18

Duncan S Allen, M D, Seneca, N Y, Albany (N Y) Medical College, 1865, was found dead in bed, December 23

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

THE WILLARD PYORRHEA TREATMENT

Oren Oneal's New Brand of Quackery Is Barred from the United States Mails

After defrauding the public of amounts estimated by federal investigators at $75,000 a year by means of a fake "cure" for pyorrhea, F W Willard, M D, D D S, has been denied the use of the United States mails Willard himself seems to have been merely a hireling, for the official report of the government declares that the owner of the business was Dr Oren Oneal Some of our readers will remember Samuel Hopkins Adams' characterization of Oneal in his "Great American Fraud" series At that time Mr Adams said

"If I were organizing an American Institute of Quack Specialists I should select Dr Oren Oneal of Chicago as the first president The artful plausibility of his advertising, his ingenuity in 'jollying along' the patient for his reluctant dollars the widespread familiarity of his features through the magazine advertising pages, and, above all, his sleek and polished personality, make him the natural candidate"

And more to the same effect Mr Adams went further He investigated Oneal's methods with some degree of thoroughness and when he brought to the quack's attention concrete examples of the disreputable methods employed, Oneal insisted that all Mr Adams had against him were "a few technicalities" To this Mr Adams responded

'Dr Oneal is proceeding on a false premise I have nothing against him, I found him a singularly agreeable and frank specimen of the genus Quack But every man, woman and child who reads his advertisements has this against him and against the magazines that print his stuff, that he is a maker of lying promises, a deliberate swindler, and a tamperer with blindness at the peril of others, for a fifty-dollar fee"

This was over ten years ago Eye-quackery stock having, apparently, taken a slump, Oneal has turned to tooth-quackery and the blatant advertisements of the Willard concern have for some time been an offense against decency and honesty

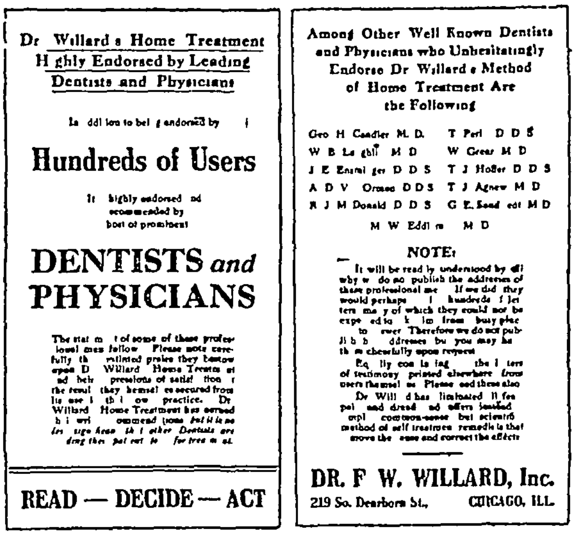
The company seems to have been incorporated under the Illinois law in 1912 At that time its president was one M L Katz who, it seems, had been engaged in the advertising business in a small way Willard was at first vice president and secretary, while Oneal was the third member of the corporate body In 1915, Oneal acquired Katz's interest and Willard became president with Oneal as general manager It was brought out in the government investigation that Willard received a salary for his services as "president and medical advisor" and claimed to have nothing to do with the business management of the fakery which he stated was under the sole direction of Oneal

In July, 1916, Willard was called on by the government to show cause on or before Sept 26, 1916, why a fraud order should not be issued against him and the company On the date set, Willard and Oneal presented themselves at the office of the solicitor of the Postoffice Department having as their legal representative one W M Ketcham of Chicago Ketcham apparently operates a business having the somewhat imposing name 'Federal Advisory Association" Ketcham was a postoffice inspector for a number of years but in 1910 went into business for himself The apparent object of the "Federal Advisory Association" is to furnish information, to those willing to pay for it, on the question of how they may use the United States mails without technically violating the law From other material in our files, it seems that the "Federal Advisory Association" also essays to offer suggestions on the wording of "patent medicine" labels and cartons

Francis W Willard was graduated by Marion Sims College of Medicine, St Louis, in 1891 This fact, verified by the records, is admitted in one of the Willard booklets which states further "After practicing medicine for some time he began the study of dentistry and was graduated from the dental department of the Washington University" Curiously enough, however, another piece of advertising sent out by the Willard concern is a photographic reproduction of Willard's alleged diploma from the dental college This diploma gives the date of his dental graduation as 1890—one year *before* he was graduated in medicine! According to our records, Willard was a dentist at Anna, Ill, for a number of years before coming to Chicago

PYORRHEA CURED BY MAIL!

The business of the Willard concern was the sale on the mail-order plan of a so-called home treatment for pyorrhea or Riggs' disease The treatment" consisted of five remedies, three to be taken internally and two to be used in the mouth The price asked was $5 for an amount sufficient to last thirty days if used in accordance with directions Advertisements placed in such newspapers and magazines as were not above participating in the profits of this fraud were the mediums by which Willard-Oneal got in touch with their victims The advertisements urged the reader to send for the free illustrated book and full information regarding the alleged treatment Those that sent for it received a small booklet with circular matter and an order blank The following quotations from the booklet indicate the character of the claims made for the treatment



Dr Willard s Home Treatment
Highly Endorsed by Leading
Dentists and Physicians

Hundreds of Users

DENTISTS *and* PHYSICIANS

Among Other Well Known Dentists
and Physicians who Unhesitatingly
Endorse Dr Willard s Method
of Home Treatment Are
the Following

NOTE:

DR. F W. WILLARD, Inc.
219 So. Dearborn St., CHICAGO, ILL.

One of the circulars sent out by Willard professed to contain testimonials from leading dentists and physicians' together with the names of such physicians who had unhesitatingly endorsed' Willard's treatment Here are two pages of this circular reproduced in miniature

> I have originated and perfected my two fold treatment—a treatment which is both local and constitutional—which has had and is having such remarkable success I may claim in all modesty that I probably have treated more cases of Pyorrhea than any other dentist in this country and the fact that I have been so universally successful proves that my treatment is correct This is why you should pay close attention to one who knows the real and underlying cause of this trouble and who knows how and why it may be relieved by a simple, inexpensive home treatment
>
> Dr Willard's treatment is a two fold or combination treatment Dr Willard s treatment consists of remedies for relieving and counteracting the local conditions *in the mouth The first essential is absolute clean* liness and this is secured by ingredients carefully and scientifically compounded for this special purpose that kill the surface germs and render the mouth tissues antiseptically clean It was necessary to spend a great deal of time in experimentation before it was possible to produce a remedy that was at the same time very powerful as a germicide and cleanser and non irritating to the delicate mucous membrane of the mouth In addition to these qualities it contains the wonderful remedy Emetine, which is claimed by many noted authorities to be an absolute specific for Pyorrhea There is no alcohol or any harmful substance in it
>
> The next step after antiseptically cleansing the mouth and gums is to combat the diseased condition existing in the gums themselves This is accomplished by means of a medicated cream—extremely penetrating —that is gently rubbed into the gums with the finger Its effects are apparent almost at once and great relief may be confidently expected from the very start"

PLAYING ON FEAR

In all his "literature' Willard emphasized and kept ever before the mind of the reader the fact that some dental operations are accompanied by pain while his mail-order treatment was painless For instance

> Painful Operations and Treatment may Be Avoided'
>
> With Dr Willard s treatment there is absolutely no suffering of *any kind'*
>
> Loose and diseased teeth may be restored to their normal health and firmness without the least discomfort"
>
> The gums may be healed without the slightest pain'

The entire scheme is well set forth by Judge W H Lamar, solicitor for the Postoffice Department, in his memorandum to the postmaster-general recommending the issuance of a fraud order We quote freely from the memorandum

"The booklet contains a number of testimonials from persons who are alleged to have used Dr Willard's home treatment with success Nearly all of the testimonials relate to cases of pyorrhea which were in advanced stages, and a careful reading of the entire booklet unquestionably leads the reader to believe that the treatment in question will cure practically all stages of the disease In the booklet Dr Willard gives the customer certain alleged symptoms of pyorrhea, and by the use of these symptoms and the symptom blank already referred to the patient diagnoses' his own case Dr Willard states

> SYMPTOMS OF PYORRHEA OR RIGGS DISEASE
>
> It may be that you who read this are already in the clutch of this awful disease of Pyorrhea, sometimes called Riggs Disease and that you now know it If you are in doubt read the following pages whereon the symptoms are enumerated and make sure To conclude that Pyorrhea is not present when it is and to neglect immediate treatment on that account would indeed be a grave mistake and one which you might very well repent for the balance of your life Therefore, make sure Then act AT ONCE
>
> Read the following and determine how far the disease has advanced in your case

"Testimony of the experts at the hearing clearly shows that it is impossible for a patient to diagnose his own case for the reason that a diagnosis of pyorrhea requires considerable clinical experience, and further that it is impossible for a dentist to diagnose pyorrhea without examination of the patient Even when a personal examination is made it is possible for a dentist who is a beginner to mistake other mouth lesions for pyorrhea or vice versa It appears that gingivitis, caused by lack of care in the mouth, and certain catarrhal conditions will often simulate pyorrhea

"Reading of the booklet gives the impression not only that Dr Willard's home treatment will cure practically all cases of pyorrhea, even in advanced stages, eliminate all pain in connection therewith, and save the patient large sums of money which he would otherwise have paid to dentists but instills in the minds of patients who are in fact not suffering from pyorrhea in any form, fear of the disease

THE "TREATMENT"

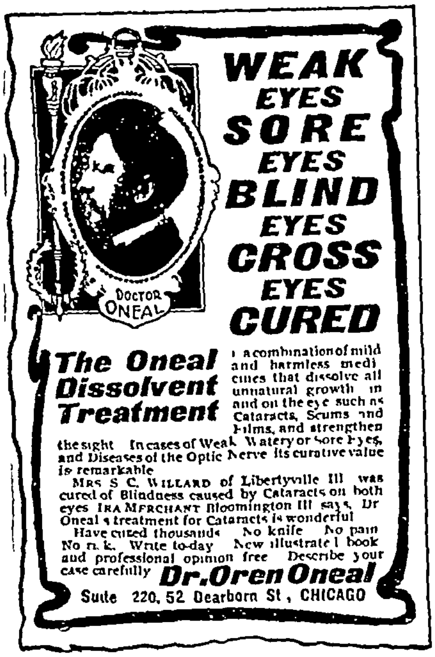
The ingredients in the Willard treatment were analyzed by the Bureau of Chemistry Department of Agriculture, and the government's report gives a detailed analysis of the preparations The findings of the government chemists can be summarized as follows

DR WILLARD S K-3 TABLETS—These were sugar coated tablets with a menthol flavor consisting essentially of the sulphocarbolates of zinc and calcium and a small quantity of the bismuth salt Practically half of the tablet was made up of a mixture of starch, sugar and talc

DR WILLARD'S L-2 TABLETS—These were light tan in color and contained washing soda baking soda Glauber salts and resins with a trace of colchicin Over 38 per cent of the tablets was a mixture of starch and talc

LAXATIVE LIVER TONIC TABLETS—These contained some laxative drug such as cascara aloes or podophyllin Over 70 per cent of the tablet was made up of a mixture of chalk, gypsum, talc and sugar

DR WILLARD'S DENTOL—These were tablets that the purchaser was told to dissolve in water and use the solution as a mouth wash Great stress was laid on the fact that the tablets contained emetin The federal chemists found that over 96 per cent of the tablets was made up of milk sugar and boric acid, while there were small quantities of menthol, thymol and eucalyptol The total ipecac alkaloids (emetin) found by the chemists was only fifteen-hundredths of 1 per cent The Willard concern claimed that paraform was also present in these tablets but it was not found



The Oneal Dissolvent Treatment is a combination of mild and harmless medicines that dissolve all unnatural growth in and on the eye such as Cataracts, Scums and Films, and strengthen the sight In cases of Weak Watery or Sore Eyes, and Diseases of the Optic Nerve its curative value is remarkable

Mrs S C. Willard of Libertyville Ill was cured of Blindness caused by Cataracts on both eyes Ira Merchant Bloomington Ill says, Dr Oneal s treatment for Cataracts is wonderful

Have cured thousands No knife No pain No risk Write to-day New illustrated book and professional opinion free Describe your case carefully **Dr. Oren Oneal**

Suite 220, 52 Dearborn St , CHICAGO

Photographic reproduction reduced of an old time advertisement of Oren Oneal in the heyday of his eye quackery

Dentifirm —This, Willard claimed was "something absolutely new to the dental profession—a massage preparation for the gums of rare medicinal, as well as unusual cleansing qualities' The federal chemists found that it was a mixture of glycerin, starch, borax chalk and soap flavored with oil of cloves and colored with a red dye!

Quoting from the solicitor's memorandum

'The treatment contains a small amount of emetin, one of the constituents of ipecac which in recent years has been brought forward as efficacious in the treatment of pyorrhea A difference of opinion exists among the profession as to the value of emetin applied subcutaneously by injection into the arm or by the use of a blunt needle forcing the solution into the pus pockets which are found about pyorrheal teeth The Willard treatment does not contemplate the use of emetin in either of these ways Instead, a small amount of emetin is put in the dentifirm paste with which the patient massages his gums The expert witnesses agreed that even were emetin possessed of value its administration in such small doses as are contained in the Willard treatment and in the manner prescribed would have no effect '

The government called oral surgeons, pathologists and dentists, all of whom agreed that Willard's home treatment administered by the patient himself at his home would be ineffective to cure or relieve pyorrhea An interesting feature of the government's investigation was the documentary evidence collected by Inspector D F Angier of the Chicago division, who as readers of The Journal will remember, has done particularly valuable work in investigating other medical mail-order frauds In the course of his investigations of the Willard concern Inspector Angier wrote to Willard, under various names, describing various mouth disorders, none of which indicated pyorrhea in any form In reply to all of his inquiries, the inspector received in every case the booklet 'How to Save Your Teeth, A Home Treatment for Pyorrhea" which has already been quoted from He also received the customary form letters and circular matter soliciting orders for the Willard treatment

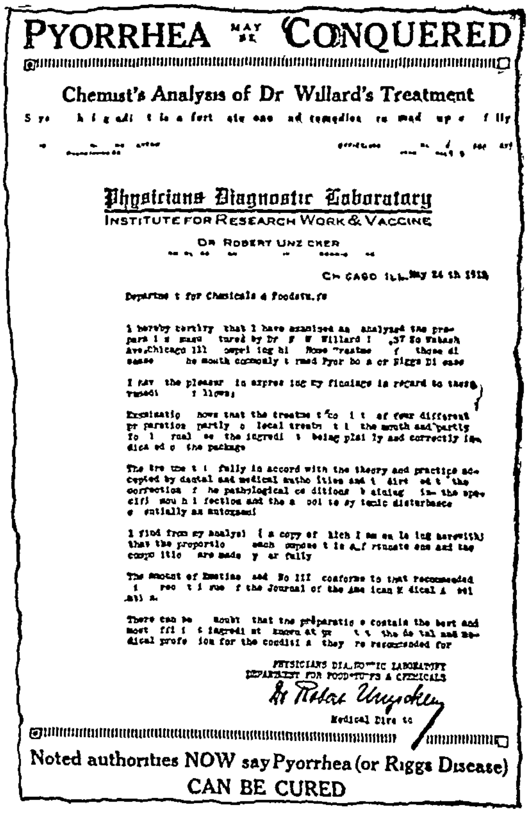
In one instance the inspector sent $1 for a "trial order" of the "treatment" The treatment was sent and thereafter Mr Angier received a series of form letters urging him to purchase the full treatment which was offered at $4, instead of the usual $5 In the particular instance in which this "trial treatment" had been sent, Willard had already acknowledged in a letter to Inspector Angier that the case described was not one of pyorrhea but a condition which the Willard treatment was not claimed to benefit To quote further from the solicitor's memorandum

"All of the letters received by the inspector in the course of the correspondence were signed 'F W Willard, M D D D S,' and even the form-letters have a decidedly personal tone calculated to lead the patient to believe that they were written by Dr Willard Dr Willard on cross-examination stated that he had no knowledge of the letter in which a case was diagnosed as a mild case of pyorrhea and it appeared as a matter of fact that a rubber stamp signature was used The rubber stamp was so excellent an imitation of Dr Willard's signature that he himself on cross-examination was unable to state whether letters had been actually signed by him or stamped There is no doubt that in all cases the patient thought he was receiving a personal letter from Dr Willard, and further that it was the intention of both the owners of the concern and Dr Willard to create the impression that the patient was receiving his personal attention and professional advice

SUMMARY

The whole scheme is well described toward the end of the solicitor's memorandum thus

"In summary, it may be said that the respondents are selling through the mails a worthless home treatment for pyorrhea to any one who will buy it, irrespective of whether or not he has pyorrhea, or, if he has pyorrhea, irrespective of whether or not it has reached that incurable stage which they admit exists, that in order to increase their business



PYORRHEA MAY BE CONQUERED

Medical Director

Noted authorities NOW say Pyorrhea (or Riggs Disease)
CAN BE CURED

One of the traditions of mail order quackery is that some sort of an analytical report should be published endorsing the treatment advertised The Willard Oneal concern held to the tradition Here is a reproduction greatly reduced of a self styled analysis of the Willard treatment issued by one Dr Robert Unzicker who did business under the imposing title Physicians Diagnostic Laboratory So far as our records show Unzicker is not a physician they are leading persons suffering from minor mouth disorders to believe themselves to be afflicted with pyorrhea, claiming it to be a 'loose term' whereas in fact it has a *definite medical significance that the public has already been* defrauded of several hundred thousand dollars through the operations of the respondents, and finally that if prompt steps are not taken to prevent further use of the mails by the respondents the public will not only be further defrauded, but those suffering from pyorrhea will be discouraged from securing proper treatment which might save the teeth if taken in time '

From the memorandum it seems that Willard and Oneal made a strenuous effort to continue taking in the $75,000 annually and submitted to the postoffice department a new set of advertising urging that they had completely modified the claims previously made They stipulated that if permitted to continue in business they would not advertise their treatment as for pyorrhea or Riggs' disease nor use the mails to solicit money for the sale of a pyorrhea treatment The solicitor of the Postoffice Department called attention to the fact that under the stipulations suggested, the Willard treatment could still be advertised and sold through the mails provided no mention was made of pyorrhea or Riggs' disease As Willard-Oneal had claimed throughout the hearing that the "Willard Treatment" was specially designed for the relief of pyorrhea, the suggested stipulation was a virtual admission that its sale for such a purpose was fraudulent The solicitor pointed out that it was difficult to understand why it should be deemed valuable for any other purpose than the one for which it was claimed to be specially prepared The memorandum closed with the following recommendation

"After a careful consideration of all of the circumstances of this case I am convinced that it is one in which the protection of the public demands the issuance of a fraud order I find that this is a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises and therefore recommend that a fraud order be issued against the names appearing in the caption of this memorandum'

The fraud order was issued, Dec 28 1916

Compulsory Health Insurance Unnecessary as a Public Health Measure

To the Editor —In view of the fact that the propaganda for compulsory health insurance is made to rest largely on the assumption, which, however, is quite erroneous, that the health progress of countries under social insurance has been more pronounced or effective than the corresponding health progress of countries which have not established at least compulsory health insurance, such as the United States, Canada and Australia, or any one of the great South American republics, it may interest your readers to know that during the last twenty years the sanitary progress of the cities of New York and Berlin has been as follows

Comparing the period 1888 1892 with the period 1908-1912, since there are no trustworthy data of a later date for the city of Berlin, it appears that the general death rate of New York decreased from 25 8 per thousand to 15 5, or 10 3 per thousand, equivalent to 39 9 per cent The death rate of Berlin during the same period decreased from 20 9 per thousand to 15 1, or 5 8 per thousand, equivalent to 27 8 per cent The average death rate of both cities during the period 1908-1912 was practically the same It would therefore seem entirely erroneous to claim that the sanitary progress of the largest city of Germany was to a measurable extent affected by compulsory health insurance

The mortality from pulmonary tuberculosis in the city of New York decreased from 32 4 per 10 000 during the first five years of the twenty-year period to 18 1, or 14 3 per 10 000, equivalent to 44 1 per cent The corresponding decrease in the pulmonary tuberculosis death rate of Berlin was from 28 3 per 10,000 to 17 9, or 10 4 per 10 000, equivalent to 36 7 per cent The actual as well as the relative decrease in the pulmonary tuberculosis death rate was therefore more pronounced in the city of New York, *without* compulsory health insurance, than in the city of Berlin, where practically the entire wage-earning population is subject not only to the provisions of the compulsory health insurance law, but also to the even more drastic provisions of a compulsory invalidity insurance law It may be said in this connection that very little, indeed, has been done by sickness insurance societies in the direction of the prevention and cure of tuberculosis among wage earners What has been done in this direction has been almost exclusively in connection with invalidity insurance for the obvious reason that the comparatively short period during which medical attendance is provided would be of little, if any, real value in connection with the treatment of chronic or prolonged diseases

The mortality from typhoid fever, which is perhaps the most sensitive index of sanitary progress, decreased in New York City from 2 5 per 10,000 to 1 1, or 1 4 per 10,000 equivalent to 56 per cent The corresponding decrease in the typhoid fever death rate of the city of Berlin was from 1 4 per 10,000 to 0 3, or 1 1 per 10 000, equivalent to 78 6 per cent The actual reduction in the typhoid fever death rate of the city of New York was therefore greater than the corresponding reduction in the typhoid fever death rate of Berlin, which, however, has now been reduced so low that the mortality is practically negligible However, it requires to be considered that the city of New York has had to assimilate an enormous immigrant population aside from the fact that large numbers annually go on vacation and contract typhoid fever in unsanitary resorts etc It is a safe assumption that a large portion of deaths from typhoid fever in the city of New York at the present time are cases contracted outside of the city

An equally sensitive index of effective sanitary progress and control is the mortality from diphtheria and croup The *death rate from these diseases in the city of New York* decreased from 13 3 per 10,000 to 3 2, or 10 1 per 10,000, equivalent to 75 9 per cent The corresponding decrease in the death rate of Berlin was from 8 3 per 10,000 to 3 3, or 5 0 per 10,000, or 60 2 per cent The mortality from diphtheria and croup is now almost exactly the same in the two cities, and it may safely be asserted that the reduction has been achieved in both cities without any reference whatever to compulsory health insurance

A large amount of additional statistical and other evidence can be brought forward to prove that the sanitary or public health progress of the German Empire has not been in advance of corresponding progress made in this country or Canada or Australia Since the death rate is practically proportionate to serious sickness rate, it is a safe conclusion that the general health conditions of this country, with particular reference to wage earners, are, broadly speaking, more satisfactory at the present time than at any time in the past, and that therefore the establishment of compulsory health insurance as a public health measure is wholly unnecessary

Blood Transfusion

To the Editor —In your answer to the inquiry of M Y D regarding blood transfusion in The Journal Nov 25 1916, it was stated that 'in November, 1666, according to the diary of Samuel Pepys, blood transfusion from one dog to another was performed" I should like to amplify your perfectly correct quotation for the benefit of M Y D and others interested in the subject

It was in February, 1665, that Richard Lower, while working in Thomas Willis' laboratory at Oxford, transfused blood from one animal to another Lower was "that expert anatomist" who had assisted Willis in his dissections of the brain and had drawn, with Christopher Wren, the later famous architect, some of the remarkable plates for Willis' celebrated book "Cerebri Anatome" It is thought that Wren first suggested the transfusion experiments following some infusion experiments which he had done in the Oxford laboratory

Lower's demonstrations were carried out before several of the Oxford doctors and a few months later before the Royal Society in London An account of Wren's early experiments with the help of Robert Boyle, the physicist, is found in No 7 of the *Philosophical Transactions of the Royal Society* for Dec 4, 1665, and Lower's transfusion before the Royal Society in No 20 Dec 17, 1666 Lower transfused first from vein to vein and later from carotid to jugular by the aid of a quill, using sheep for demonstration purposes During that same year M Denis and M Gayant performed similar experiments in France A letter from M Denis is published in No 25, May 6, 1667, of the *Transactions*

Interesting discussions on the dispute which arose at the time as to the priority of transfusion are also found in the *Transactions* for May 6 and Oct 21, 1667 It seems certain that as early as 1660 Wren, Lower and Boyle had carried out, at Oxford, experiments on infusion and later on transfusion of blood Boyle injected opium (through a quill into a vein), stupefying an animal It was not, however, until May 17, 1665, that a public demonstration of transfusion was held at the Royal Society in London The Royal Society notes that 'a Benedictine Fryer discoursed of it at M de Monmours, ten years ago," but there is no more evidence to strengthen this French claim The report of the Royal Society wisely concludes, "But whoever the Parent be, that is not so material as all that lay claim to this child should joyn together their efforts and cares to breed it up for the service and relief of human life, if it be capable of it, and this is the main thing aimed at and sollicited in this Discourse'

'In accordance with this sound advice transfusion experiments proceeded, and were soon carried out on human subjects For instance on November 23, 1667, transfusion was practiced in a medical case on one Mr Arthur Coga at Arundel House London, in the presence of 'considerable and intelligent persons,' by Dr Lower and Dr King, the blood of the sheep being used Their report states that the man after this operation as well as in it found himself very well, and hath given his own Narrative under his own hand enlarging more upon the benefit he thinks he hath received by it than we think fit to own to as yet " (Gotch, "Two Oxford Physiologists, Lower and Mayon," Oxford, 1908) The carotid of a sheep was connected to a vein in Coga's arm by a silver tube The full report appears in the *Philosophical Transactions* No 30, Dec 9, 1667

Henry Viets, M D, Oxford, England

Lack of Efficient Teaching in Urology

To the Editor —I have read, with interest and approval, Dr Irvine s "Notes on the Teaching and Treatment of Syphilis' (The Journal, Dec 30, 1916, p 1987) I agree with him that medical colleges are not preparing their graduates to combat syphilis effectively, and that a social injustice is thereby perpetuated

In urology, a like condition exists In over ten years' service at the North Hudson Hospital I have not found one intern who was really competent to treat gonorrhea or to use the catheter And most of them came from New York medical schools, which certainly do not lack material for teaching clinical urology

These men are familiar with the cystoscopic appearances of the bladder, and know the indications for and technic of such operations as nephrectomy and prostatectomy They have been taught major procedures which few of them will ever have occasion or desire to perform, but not how to meet the every-day urologic problems of a general practice

Not a few recent graduates, therefore, progressive in everything else, even syphilis, treat urethral disease as their forefathers did For gonorrhea they prescribe the same old balsamics and gastro-irritants and the same astringent injections, spoiling their patients' stomachs and laying the foundations for infiltrations and strictures, but not actually curing the disease

This is not the fancy of an alarmist It is a sober estimate of existing conditions, based on a fair sized urologic practice In the cities, conditions are better than formerly, owing to the great recent development of urology Many city practitioners habitually refer their urethral patients to the urologist, and many patients go to him directly

The safe and proper technic of urethral instrumentation and irrigation are a matter of manual training, to be acquired by plenty of actual work done under expert supervision The genito-urinary clinics of our large medical centers offer more than enough material for practice

The responsibility for this lack of training lies with the colleges C L DeMeritt, M D, Hoboken N J

TREATMENT OF CEREBRAL HEMORRHAGE

To the Editor —One of my patients, a woman aged about 68 has partial paralysis of the left side due, I think to cerebral hemorrhage I should like to know the latest accepted treatment of this condition

G M H, M D, Lancaster Ky

Answer —It is exceedingly difficult to advise regarding the treatment of a person without more complete details of history and physical findings, since each patient presents a special problem Presumably this patient is partially paralyzed from 'cerebral hemorrhage' with no other complications

This is the commonest cause of the condition described by our correspondent Embolism or thrombosis of cerebral arteries may also give a similar result In general the treatment should consist of rest in bed immediately following the attack The bowels should be moved if necessary with a mild cathartic Good nursing care is important and adds to the comfort of the patient In the days immediately following the onset of paralysis, the position of the patient should be changed from side to side at intervals The use of inflated rubber rings and cotton pads will assist in preventing pressure necrosis of the skin of the back, heels, etc Later in the course, massage and passive motion will aid in preventing contractures

Other special features of the individual case may call for changes or additions in treatment Arteriosclerosis is frequently accompanied by cardiac hypertrophy and increased blood pressure, and, in plethoric persons, bleeding has sometimes been advised to reduce blood pressure Cerebral hemorrhage may, however, occur in persons in whom arteriosclerosis is not accompanied by greatly increased pressure The possibility of syphilis as a cause of the arteriosclerosis should be investigated, and when it is found, iodids and later mercury are indicated Small doses of iodids are often advised in nonsyphilitic arteriosclerosis

Other causes of hemiplegia of central origin, such as tumors, in a person over 60, usually give rise to additional symptoms and physical signs which will be discovered in the course of the routine examination which should be made of every patient no matter what the complaint

While cerebral hemorrhage with resultant hemiplegia may often result fatally in the first attack, the patient may recover the use of the extremities to a surprising degree, and by living a quiet life with moderation in all respects, may exist in comfort for years

INCOMPATIBLE DISEASES

To the Editor —Can you give me the title of any books or articles on diseases incompatible to each other *that is* diseases which cannot exist in the human body at the same time?

F W S

Stronger Tests for Drugless Healers

The Illinois State Board of Health has ruled that drugless healers are to be given the same examination as physicians, except in surgery, obstetrics materia medica and therapeutics Drugless healers are not authorized by law to practice operative surgery or obstetrics nor are they to use drugs or medicines internally in their practice Examination papers on "practice" are to be graded by members of the various schools of healing selected by the state board of health for that particular purpose Formerly drugless healers were given a comparatively simple examination in anatomy, chemistry physiology, pathology and histology symptomatology, and hygiene The examination now covers seven groups of subjects anatomy, chemistry, etiology and hygiene, physiology and neurology, pathology and bacteriology, physical diagnosis ophthalmology and otology, and pediatrics, gynecology, laryngology, rhinology and medical jurisprudence, and practice

New Jersey and Chiropractic Colleges

The Department of Public Instruction of New Jersey states that the New York School of Chiropractic, located in New York, and supposedly operating under a New Jersey charter, has not been chartered or registered in New Jersey, and that the New Jersey College of Chiropractic, located at Newark, N J, although chartered in the state was, on May 1, 1915 refused permission by the state board of education to grant degrees

Book Notices

THE TREATMENT OF DIABETES MELLITUS With Observations on the Disease Based on 1 000 Cases By Elliott P Joslin, M D Assistant Professor of Medicine Harvard Medical School Cloth Price, $4 50 net Pp 440, with illustrations Philadelphia Lea & Febiger, 1916

'In writing this book," the author says, "I have tried to record those facts which have proven of service to me in the treatment of diabetes," and it is in this sense that the title gives a true index of the scope of the work, for the writer has by no means limited himself to the discussion of those things which in a narrower sense would be classified under the heading of treatment It represents in reality a summation of the work done by Dr Joslin and his co-workers on the subject of diabetes "For the benefit of my patients," he adds, 'it has seemed worth while to summarize my work with them during the last eighteen years, and I have honestly tried in these pages to let the 400 fatal cases tell their useful lessons to the 600 living"

Whereas in addition to such able and well known foreign treatises as those of Naunyn, Lepine and von Noorden, there have appeared within the last four years three other volumes on diabetes from the pens of American writers, while a fourth is in course of preparation, making in all five American books on diabetes within as many years, one may properly ask what new or special phase of the subject or what improvement in the method of exposition this one is designed to present "I would not have wished to write a book on diabetes three years ago," says Joslin, "today it is a pleasure and an inspiration because the improvement in treatment is beyond question The introduction of fasting and the emphasis on physical exercise by Dr F M Allen, of the Rockefeller Institute for Medical Research, has decidedly changed the outlook for this class of patients It is encouraging to be able to report that during the last year the mortality of my patients was approximately 20 per cent lower than for the previous years" A fresh presentation of the subject of treatment, with particular reference to the use of inanition and exercise, as taught by Allen, is, then, the distinguishing feature of this book

There are seven sections the first (sixty pages) after preliminary definitions and distinctions between diabetic and other forms of glycosuria, in which prominence is given to the views of Allen is devoted to statistics relating to diabetes Conditions relating to diabetes within the United States receive a fuller exposition in this section than they have yet had elsewhere, and some new ground is covered It will be found of value particularly to American readers for reference purposes The second section of the book (seventy-seven pages), entitled "Important Factors in the Treatment of Diabetes" consists of subsections devoted to a variety of subjects, such as "Naunyn's Conception of Diabetes Mellitus", "Allen's Hypothesis Diabetes—A Weakness of the Pancreatic Function' , Is the Tendency of the Diabetic Glycosuria to Increase? , "If the Urine of the Diabetic Patient is Sugar-Free, the Tolerance for Carbohydrates usually Improves", "Hyperglycaemia" (twelve pages), based largely on original observation and recent American literature, "Blood Fat" (five pages), written by Prof W R Bloor of the Harvard Medical School and "Metabolism in Diabetes' (thirty pages), containing a discussion of the total metabolism in diabetes, observations on the respiratory quotient and a consideration of contingent topics based on the studies of Benedict and Joslin on individuals in the fasting and diabetic states This section ends with a chapter on acidosis In the sense that all obtainable knowledge of diabetes may prove of service in the treatment of cases, the material of this section bears on treatment some of it directly But it is of interest more especially from the standpoint of physiology Some features of this section will be referred to again The third section is on methods of examining the urine, blood and respirations The fourth section (twenty-eight pages) is devoted to principles of dietetics with special reference to diabetes The fifth section (130 pages) takes up the treatment proper

The use of inanition and the views of Allen are fully presented with many citations of cases The sixth section, referred to in the preface as a "diabetic's primer," has a content indicated by the following captions "What Every Diabetic Should Know", "Directions for Nurses in Charge of Diabetic Patients", "A Diabetic History Chart for the Use of Institutions and Physicians", "Chart for Dietary and Urinary Records", "Actual Diets Employed to Render Patients Sugar-and-Acid-free", "Hospital Treatment", 'Ambulatory Treatment," etc The last section contains food and diet tables, recipes, menus, methods of recording hospital diets and tables of equivalents

The book as a whole forms a compact, well printed volume written in an intimate, readable style It is interesting to note a transition in the character of the writer's work from the earlier to the later periods, for the first part of the book patterned unmistakably after Naunyn and reflecting a time in the development of American medicine when statistical clinical studies of the Oslerian type prevailed, contrasts noticeably with the latter sections, based largely on the yield of an intensive experimental study If in the past American writers have had just cause to complain of a neglect of their work by foreigners, they will have none here The American literature receives all the credit due it, not to say more That diabetes implies a weakness of the pancreatic function is an idea ascribed to Allen

The discussion of treatment based largely on the extended use of inanition and the emphasis on physical exercises by Allen is full, clear and illumined by many original comments based on a wealth of clinical material, handled with system and scrupulous exactness of detail It is a significant contribution to clinical medicine Noteworthy are the specific directions for the graduated increase of diets without causing recurrence of symptoms in cases of severe diabetes which have been rendered sugar-free by fasting The method of building up first the carbohydrate of the diet, then the protein, then the fat, the emphasis laid on the importance of finding and not exceeding the tolerance for fat, and of keeping the total food allowance within narrow enough limits will doubtless explain to many who have failed to keep patients with severe diabetes free of symptoms why they have failed On the other hand out of 184 cases treated in twenty-four years by fasting, there were thirty-one fatalities, twenty-one of the patients dying in typical coma, the rest with complications such as coma and gangrene 1, uremic coma, 1, appendicitis, 2, carbuncle, 1, pulmonary embolism, cancer, anuria, tuberculosis, each 1, cardiac, 2 Dr Joslin however, does not admit that in any of these the fasting treatment, properly carried out hastened the end In this connection it should be said that fasting practiced by other clinicians, and even by some who are not open to criticism on the score that they have not carried it out intelligently, has nevertheless been observed to shorten life in a certain small fraction of cases It will doubtless continue to be felt by some that human individuals in certain conditions can be injured or killed by withholding food and that if such persons, in addition to their other ailments, should happen to have a deficient pancreatic function besides, they may still be injured by fasting This might be said to apply to some pluriglandular complexes with goiter and to all end-stages of inanition itself It is to be regretted that in this book the writer has not set out with equal clearness, over against the indications for inanition, those situations in which it is no longer of any value or in which it may perhaps prove to be contraindicated

The sections devoted to topics of interest chiefly from scientific points of view are useful especially because they contain many new and valuable clinical data and convenient collections of the recent published work of American writers

This book will enable any physician who has diabetic patients under his care, and who will carry out the directions given, to obtain better results with his cases than are obtained by ninety-nine out of a hundred practitioners at the present time It may be placed in the hands of nurses and patients with the result that the physician will receive intelligent cooperation and execution of his general orders, relieving him and his patients of annoyance and loss of time It will thus perform a high humanitarian service It is, moreover, a storehouse of data for the investigator to draw on when desired, and there will be few persons interested in diabetic metabolism from any standpoint at all who may not learn something of value from reading it through

Social Medicine, Medical Economics and Miscellany

Quackery in Switzerland

In 1914, Dr H Hunziker of Basel sent out a question blank to several hundred physicians in Switzerland asking for data on the quacks in their vicinity—the numbers, names former occupations the diseases they claim to treat in particular, their remedies, whether their clients are natives or tourists, and whether they treat by correspondence He reports in the *Correspondenz-Blatt fur schweizer Aerzte*, Sept 23, 1916 that most of the blanks were returned, and he comments on the data thus obtained They show that in the different cantons there are from 0 08 to 6 04 quacks per 10,000 inhabitants Two of the cantons place practically no restrictions on the practice of medicine, and one has 134 6 quacks to every hundred physicians In the whole country there are 198 known quacks to 2 500 registered physicians, that is, 7 4 professional quacks to every hundred physicians The laws in regard to the practice of medicine and advertising and sale of proprietaries differ widely in the different cantons which renders it particularly difficult to combat evil practices Important progress was realized in 1900, when a central committee was organized to pass on proprietaries To date eleven cantons have joined this organization The central committee consists of a physician a pharmacist and a chemist They are appointed by the public health authorities of the canton of Zurich and have a laboratory at Zurich where they examine all secret medicines and pharmaceuticals sent in for the purpose by the cantonal boards of health They are tested for possible injury to health, suitable composition fraud in advertising in labels and circulars, and selling price as compared with the value The report on each is distributed to each of the cantonal boards of health and also to the national public health service Up to April, 1916, they had thus reported on 921 proprietaries The reports are published in the official weekly bulletin for Switzerland, the *Sanitarisch Demographische Wochenbulletin* Hunziker calls on the medical societies of the cantons to watch for neglect or lax enforcement of existing regulations on these evils unpleasant as the task may be We must bend our efforts further to have the gaps in the existing laws filled up From one canton which puts no restraint on these practices, the whole country is flooded with the quacks' circulars By looking up the past records of the quacks means can often be found to drive them out of the country It is the duty of the state to protect its citizens against fraud"

He outlines further a plan for a propaganda, enlightening the public by lectures, press articles, pamphlets etc 'We must not wait for such opportunities, we must make them We physicians are the leaders of the people in hygienic questions It is our duty to enlighten them in the field of care of the health People long for general information on such matters and they have a right to it, and if we do not supply it the quacks will The hygiene commission of the Swiss *Gemeinnutzige Gesellschaft* has decided to issue a pamphlet on quacks and the fight against them In conclusion Hunziker advocates founding some central office where quacks' advertisements and literature can be collected and used for propaganda purposes, placed at the disposal of physicians Here should be collected data about quacks, their former lives and records in general The medical society in each canton should appoint some member who should collect all data on quack practices and examine newspapers, etc The advertisements of quacks outside the canton should be sent to the central office for further investigation Some quacks advertise in papers outside their own canton, and nothing is known in their home town of their practices The board of health of Basel has offered to serve as the central antiquack office He adds, "A weapon has finally been found against registered physicians who stoop to cooperate with quacks Nothing is so detrimental to the prestige of the profession as this The right to practice medicine was recently withdrawn by the Basel court from a physician who was working with a quack, and the court of appeals has confirmed the decision"

Industrial Pensions in Sweden

Regulations for the inauguration of the largest private pension project in the history of Sweden were promulgated, Nov 19, 1916, at a meeting of the superior board of managers of Swedish industrial associations and various chambers of commerce according to U S Consul B M Rasmussen at Goteborg (*Commerce Reports* Jan 2, 1917)

Men pay 10 per cent of their salaries for their own pensions and 6 per cent for family pension Men from 21 to 34 women from 18 to 30, and new employees under 47 and 42, respectively are required to insure themselves Men are eligible to full pensions at 62, when they are to be paid 60 per cent of the salary received at the age of 47, no pension being computed on a salary higher than 5,000 crowns ($1,340) Those persons joining the association between 34 and 42 may receive the full pension at 63 and 65, respectively, provided they reached their maximum salaries at 42 Irrespective of the age of joining the association or of receiving the maximum salary pensioners may receive the full pension by paying premiums required in excess of the fixed maximum dues All male members whether married or single, are obliged to contribute to the family pension fund A family pension is computed at 25 per cent of the head of the family up to 5 000 crowns Children surviving both parents are entitled to a pension up to 18 A member when he reaches the pension age, unmarried and active, is to be reimbursed for all sums he has contributed to the family pension fund

As women live longer than men, their premium is 12 per cent They are entitled to full pension at 57, provided they reach their highest compensation before 38 Membership is compulsory for all employees of concerns whose owners are members Employees may be exempted if they already carry life insurance and are unable to pay additional dues

Primary Sarcoma of Pancreas

In the *Clinical Journal* Nov 22, 1916, H M Fletcher cites a case of primary round-cell sarcoma of the pancreas with metastases occurring in a boy, aged 17, who was admitted to the hospital with the following history Four months previously he suffered with pains in his chest and thighs, but he had not been away from military duty on that account Three weeks prior to admission he was affected with left facial paralysis, which was preceded by a feeling of numbness on that side of the face A week before admission the pains in the chest and thighs became much worse, the patient was constipated, but there was neither headache nor vomiting His past history was good, he had suffered from no serious illness The diagnosis was pleurisy Fletcher felt that the patient's condition was due to something much more serious than a slight attack of pleurisy coinciding with Bell's palsy He came to the conclusion, wrongly as it proved, that he was suffering from acute general tuberculosis with tuberculous meningitis This diagnosis appeared to explain the general symptoms, such as pyrexia, headache and vomiting, and also the facial paralysis The diagnosis of tuberculous meningitis was apparently confirmed by the examination of the cerebrospinal fluid and by the blood count associated with an increase of lymphocytes The postmortem examination proved it to be a case of primary sarcoma of the pancreas The meningeal symptoms were due to a minute hemorrhagic secondary growth in the dura, involving the bone There were also secondary growths in the kidneys, parietal bone, orbital plate dura mater, glands of the neck and axilla

Medicolegal

What Deemed "Personal Injury" to Employee—Erysipelas After Frostbite

(Larke vs. John Hancock Mut. Life Ins. Co. et al. (Conn.), 97 Atl. R. 320)

The Supreme Court of Errors of Connecticut affirms a judgment sustaining an award under the workmen's compensation act in favor of the claimant whose husband had been in the employ of the company soliciting insurance and collecting insurance premiums. There was a finding that the unusual exposure of the man's employment to the weather caused a frostbite producing lesions of the face, through which the germ of erysipelas entered and that disease developed, from which he died. The Court says that the first question for decision was whether the frostbite was a personal injury "arising in the course of and out of his employment." The conclusion is that it was. The Court thinks that the lesion, whether produced by a frostbite or a blow, must be held to be a personal injury within the workmen's compensation act. In either case the injury would be the result of an untoward mishap. If the term "personal injury" be given its narrowest construction and confined to injuries of accidental origin it must be held to include any form of bodily harm or incapacity, whether arising by direct contact, or lesion caused by external violence or physical force, or untoward mishap. An attempt to frame an all-embracing definition so as to include all injuries arising in the course of one's employment would probably prove its inadequacy under the changing conditions of time. In a general way, sufficient for this case, and perhaps helpful in the consideration of other cases, the Court may say an injury to an employee is said to arise in the course of his employment when it occurs within the period of his employment, at a place where he may reasonably be, and while he is reasonably fulfilling the duties of his employment, or engaged in doing something incidental to it. An injury which occurs in the course of the employment will ordinarily arise out of the employment, but not necessarily so. The term "arising out of" in this act, points to the origin or cause of the injury. Speaking generally, an injury arises out of an employment when it occurs in the course of the employment and as a proximate result of it. If the primary injury arises out of the employment, every consequence which flows from it likewise arises out of the employment. The chain of causation may not be broken. Every injurious consequence flowing from it is a part of this chain. It was immaterial that erysipelas does not ordinarily result from frostbite, it was enough if in this instance it was caused by it. All physical consequences and disease result from an injury when there is a causal connection between them.

Revocation of License for Conviction of Offense Involving Moral Turpitude

(State Board of Medical Examiners vs. Harrison (Wash.), 159 Pac. R. 769)

The Supreme Court of Washington finds no merit in the appeal of the defendant and affirms a judgment of the superior court affirming an order of the state board of medical examiners, which order revoked the license of the defendant to practice medicine as an osteopath within that state. The Court says that it appeared that a complaint was filed with the board charging that the defendant had been convicted of an offense involving moral turpitude in that she had been indicted and convicted in the United States District Court at Seattle for "knowingly by means of the United States mail, giving notice and information" to certain persons named when, how, and by whom and by what means an abortion could and would be done and performed and produced." The statute provides at Section 8397, Rem. & Bal. Code of Washington, that "Whenever any holder of a certificate herein provided for is guilty of unprofessional conduct, as the same is defined in this chapter, and said unprofessional conduct has been brought to the attention of the board granting said certificate, in the manner hereinafter pointed out it shall be their duty to, and they must revoke the same at once, and the holder of said certificate shall not be permitted to practice medicine and surgery, or osteopathy, in this state." Section 8397½ provides that "The words 'unprofessional conduct,' as used in this chapter, are hereby declared to mean First. The procuring, or aiding or abetting in procuring a criminal abortion. Fifth. Conviction of any offense involving moral turpitude, in which case the record of such conviction shall be conclusive evidence." The defendant contended that the provision that a conviction of any offense involving moral turpitude shall be conclusive evidence is void unless it shall be construed to mean that the state board of medical examiners or the courts may inquire into the facts and circumstances attending such former conviction for the purpose of ascertaining if the offense for which the person was so convicted is one involving moral turpitude. The defendant contended that this provision is a rule of evidence, and not of what is termed substantive law, and from this it was argued that it is the duty of the Court to hear the evidence and determine as a question of fact irrespective of the former conviction, whether the accused is really guilty of an offense involving moral turpitude. But whether the statute under consideration is a declaration of substantive law or a rule of evidence the Court holds is of no importance, for the Court is satisfied that the legislature has no power to declare either a rule of law or a rule of evidence in a case of this kind. The Court is satisfied that the legislature had the power and authority to pass the statute under consideration, and that it was the duty of the state board of medical examiners, when the conviction was admitted, to cancel the defendant's certificate. In such a case as this there is no discretion, either in the board or in the Court as to the penalty. The statute provides that it shall be the duty of the board to revoke the license to practice medicine in the state. That is the only penalty. It was also argued that the term "moral turpitude," as used in the statute, is so vague and uncertain as to render the law unreasonable and void, but those words are capable of accurate definition and are well understood, as was determined in re *Hopkins*, 54 Wash. 569, 103 Pac. R. 805.

Death From Accidental Septic Poisoning

(Merrick vs. Travelers Insurance Co. (Mo.), 189 S. W. R. 392)

The Kansas City (Mo.) Court of Appeals affirms a judgment in favor of the plaintiff, the widow of a practicing dentist who died while insured by the defendant under an accident policy which was stated to cover "septic poisoning the result of external inoculation through accidental contact with septic matter." The court says that the evidence of the plaintiff disclosed that the insured was apparently in good health, but had been afflicted for two weeks or more with a slight cold and its attendant inflammation of the nasal mucous membrane, though the cold and inflammation had almost disappeared at the time of his alleged infection. He was working in his office on the teeth of a patient who was suffering from a virulent and advanced attack of *pyorrhea*, when the patient suddenly coughed with explosive violence ejecting a spray of saliva into the insured's face. The next day the insured and the plaintiff attended a matinee, and on leaving the theater he complained of a headache. After returning home, the pain, which was in the forehead just above the nose, seemed to increase and extended around to the ear. He slept little that night. The next day he dressed but reclined all day and suffered from the pain, which did not abate. The next morning, which was Monday, he went to the office to keep an appointment, but returned home at 1 o'clock in a taxicab and was suffering intensely from the pain in his forehead and ear. He went to bed and had the family physician called. Constantly but gradually he grew worse and died about three months after he became bedfast. Epidemic spinal meningitis was prevalent in the city, and the insured exhibited many symptoms of that disease, and the attending physician certified that it was the cause of his death. The symptoms of the insured also were similar to those of certain syphilitic attacks. The plaintiff's evidence, however, dealt with every possible cause of diseases manifested by the symptoms of the one in question, and definitely excluded from the sphere of reasonable inference all other causes than that alleged namely, that virulent germs which were a part of septic matter were accidentally brought into the nasal passage, where by natural processes they thrived multiplied and found their way to the brain producing a condition which resulted in the death of the insured To sustain her burden of proof, the plaintiff was not required to adduce uncontradicted opinion evidence, but only such evidence as would seem reasonable to the common understanding consistent with itself and its basic facts, and which, if accepted would exclude any other conclusion than that the alleged cause of the fatal disease was the actual proximate cause To say that the plaintiff did not sufficiently prove her cause would be to hold in effect, that no liability based on the stipulation quoted could be proved if the experts of the respective parties disagreed The court did not err in sending the case to the jury

2 **Traumatic Separation of Symphysis Pubis**—The obstetric history of Beach's patient was interesting The first labor was dry and instrumental and was followed by three normal deliveries The fifth was dry and instrumental causing a third degree laceration, which was repaired three months later The sixth and seventh labors were normal but the eighth was a forty eight hour labor which was terminated by forceps Following this delivery the patient was in bed for sixteen days, suffered extreme sacral pain on motion and was unable to walk for three months after the delivery This labor was two and one-half years before the ninth or present one After the patient eventually became able to walk, she remained in fair health except for some backache after a hard day's work, or on rotary motion of the thighs During the last pregnancy, before coming to the hospital, she had no unusual symptoms and considered herself normal Admission examination showed a 40 cm fundus with a normal left occipito-anterior position, head at the brim Vaginal examination showed that the ends of the pubic bones were so widely separated that four fingers could be placed in the interval Labor progressed normally terminating at the end of thirteen hours in the spontaneous birth of a 9¼ pound baby Following the delivery the ends of the pubic bones came together to within about 3 cm of each other The puerperium was absolutely uneventful She was up on the thirteenth day, was soon walking without the least discomfort, and went home on the eighteenth day

5 **Rectal vs Vaginal Examination in Labor**—Rectal examination *alone*, or *when combined* merely with abdominal palpation in pregnancy and labor, as a substitute for vaginal examination in parturition, in Moore's opinion, is not compatible with an intelligent management of childbirth But the rectal route with abdominal palpation in pregnancy and parturition and the vaginal examination in pregnancy, subject to the rule, "When in doubt resort to the vaginal route," can be used in the majority of labors without necessitating any vaginal examination during labor Keep out of the vagina in labor except when necessary to do otherwise The author recommends primary vaginal examination in all cases first seen in labor and in all cases of delayed labor, and of course in cases in which operative interferences has been indicated, and to use the rectal route as an adjunct to a primary vaginal examination thus avoiding numerous vaginal examinations, which should always be condemned The vaginal examination should be made before rupture of the membranes the cervix being dilated, as diagnosed per rectum, and get the benefit of the autogenetic douche of liquor amnii Rectal examination and abdominal palpation in pregnancy and labor should be more thoroughly taught in medical schools

9 **Hemangioendothelioblastoma in Pregnancy**—This is a report of a tumor of the upper jaw which repeatedly grew larger during gestation became smaller after parturition and recurred after removal

15 **Dextrose Retention**—When dextrose is injected by way of the portal vein into anesthetized dogs in amounts which are below the tolerance limit (about 0 8 gm per kilogram an hour), there occurs a rapid increase in the percentage of blood sugar This rise continues until a certain level is attained, after which the blood sugar remains practically constant The time at which the constant level is attained varies with the rate of injection When the behavior of the sugar concentration is compared in blood drawn from the portal vein vena cava and iliac veins during moderate dextrose injections, it has usually been found that there is very little difference During the injection of large amounts of dextrose the H-ion concentration of the blood, as determined by the colorimetric method, very commonly becomes increased When alkali (sodium carbonate) is injected intravenously in sufficient amount to lower the H-ion concentration of the blood in animals in which the blood sugar per-

centage is initially high (etherization and operative manipulation in sugar fed dogs), there is a very distinct decrease in blood sugar, but by comparison of the curves which represent this in the portal vein, vena cava and iliac vein, it cannot be shown whether the liver or the muscles are primarily responsible for the increased retention

The injection of sodium carbonate solution or of hydrochloric acid at intervals into the portal vein during the continuous injection into another branch of the same vein of a dextrose solution does not disturb the relationship in sugar concentration normally existing in blood taken from portal vein, vena cava and iliac vein, nor do such injections cause any alteration in the level of the curves, whether these be rising or stationary When dextrose is injected at a rate below the tolerance limit, along with sufficient alkali to cause a distinct increase in p_H of the blood of the portal vein and vena cava, the blood sugar does not rise to such a degree as it does when the dextrose solution is neutral or acid in reaction

18 **Bile Pigment Output and Blood Feeding**—The flow of bile and the secretion of bile pigments in the dog are not influenced by the ingestion of fresh blood, freshly laked red cells, cooked or digested blood

19 **Effect of Feeding Bile on Bile Secretion**—Feeding fresh bile to bile fistula dogs causes an almost constant cholagogue action, with a fall in the output of bile pigments These experiments exclude the possibility of bile pigment absorption from the intestine

20 **Effect of Feeding Bile Constituents**—Taurocholic acid given by the mouth has a strong cholagogue action, but little influence on the secretion of bile pigments in bile fistula dogs Glycocholic acid has a moderate cholagogue action but a strong inhibiting effect on bile pigment secretion Cholic acid has little if any cholagogue action, but may decrease somewhat the bile pigment secretion in the bile fistula dog Bile fat (ether extract) has no cholagogue action, but has a strong inhibiting effect on the secretion of bile pigments

27 **Ischemic Myositis**—The value of the elastic traction method of overcoming the cicatricial contracture in these cases is endorsed by Taylor A brace is made on a plaster-of Paris model of the forearm so as to fit smoothly It is applied without lacing it so tightly as to interfere with the circulation Elastic finger traction is applied up to the point of moderate discomfort The apparatus is left on continuously except for two intervals of an hour each, morning and afternoon During these periods the whole extremity is immersed in hot water for twenty minutes, kept as hot as bearable by constant addition of hot water If nerve involvement is present the heat must be less and the attendant s hand should be used as a guide After the immersion, massage and vigorous passive motion is used and finally, attempts at voluntary motion encouraged When the contractured tissues have been well stretched, so as to permit a good degree of passive extension of fingers and wrist simultaneously, the apparatus is left off during the day so as to encourage active motion and use, and then worn during sleep to avoid recurrence of the contracture As the tendency to recurrence disappears the apparatus is used less and less until it is finally discarded The child is systematically trained to use and develop all the muscles which have survived

29 **Carcinoma of Breast**—An analysis of 100 consecutive cases of carcinoma of the breast was made by Oliver Four patients were under 3 years of age and 14 were under 40, 17 patients were over 60, 67 patients were between 40 and 60 years of age In 56 patients the disease was in the right breast, in 43 in the left breast The actual number of cases which have survived the three-year period, is 41 The known dead are 65, and in 4 the result is unobtainable Of those living, 1 is alive twenty-one years after operation, 3, fourteen years, 3, fifteen years, 1, thirteen years, 1, twelve years, 1 ten years, 3, eight years, 5, seven years, 3, six years, 3, five years, 3, four and a half years, 3, four years, 5, three and a half years, 1, three and a quarter years, 2, three years Twenty-two of the successful patients knew of the existence of the disease for nine months, or less, previous to operation, while 12 gave a history extending over from one to twelve years The recurrences after operation exhibit a wide range In 14 cases the metastases were internal, 7 had secondary deposits in the spine, 2 in the mediastinum, 1 in the brain, 1 in the skull, 1 in the lower jaw and one in the sternum and supraclavicular fossa Nine cases had purely local recurrences, and 8 had local and internal recurrences The other breast was secondarily involved in one patient Oliver recommends systematic postoperative Roentgen-ray treatment

30 **Reconstruction of Bile Duct**—In the case cited by Ginsburg and Speese during the performance of a cholecystectomy the common duct to which the cystic duct was parallel, was caught in the forceps applied to the cystic duct, and both structures were divided Satisfactory healing of the incision took place, except for the establishment of a biliary fistula The patient made a good operative recovery At a second operation it was found that division of this structure had taken place half a centimeter below the junction of the right and left hepatic ducts, with some loss in continuity of the duct wall Since apposition of the two ends of the bile duct was impossible, a T-shaped rubber tube was inserted into the proximal and distal ends of the bile duct and fixed by catgut sutures About 2 inches of the duct needed reconstruction and this was accomplished by enveloping the rubber tube with a section of posterior rectus sheath fascia, including the peritoneum, taken from the region of the wound The fascial surface of the transplant was placed in contact with the rubber tube, and both ends were carefully sutured to and around the proximal and distal ends of the bile duct, and also to the wall of the duodenum After a week the distal end of the T-tube broke away at the junction of the fascial transplant with the distal end of the common duct, and was impinging on the wall of the duodenum, as was determined at a third operation A small thick-walled rubber tube, slightly less in diameter than that of the common duct itself was substituted for the T-tube, and the bile duct reconstructed around this tube, carefully suturing the transplant to the distal portion of the bile duct as well as to the wall of the duodenum Four months since the successful reconstruction of the duct was accomplished, the rubber tube has not been passed, and the patient has not suffered from any symptoms suggestive of biliary colic

33 **Temporary Colostomy**—The technic devised by Shaw and Hunt is as follows Incision exploration etc, are just the same as in any type Choice of dealing with the gut, that is single barrelled, double barrelled or simple attachment of the gut to the peritoneum, is simply a matter of judgment, after such decision, grasp the gut with a crushing clamp Within the bite of the crushing forceps is interposed a piece of dentist's rubber dam, the same width as the proposed stoma and about 4 inches long The parietal peritoneum is carefully circumstitched around the gut Next apply another crushing forceps parallel and distal to the first then cut

between, cauterize with phenol and apply a Kerr basting stitch, the ends of which are brought out through the abdominal wall and tied over gauze This stitch is to be removed when necessity calls for a patent stoma At the end of thirty-six hours union between the parietal and visceral peritoneum is complete and the basting stitch may be cut close to the skin on one end and pulled out at the other The rubber acts as a guide to the stoma, which sometimes remains sealed after the stitch is removed, due to the crushing of the forceps, the introduction of the gloved finger easily overcomes this The subsequent treatment would be that following any type of colostomy, depending on the individual case

55 **Pyloric Stenosis in Infants** —During the past two years sixteen cases of undoubted pyloric stenosis have been treated surgically in the hospital for sick children in Toronto Of these sixteen cases, eleven recovered, a mortality of 31 2 per cent Of the five infants who died, one died of hemorrhage, one died sixty hours after operation with no relief of the symptoms because of incomplete operation, a third patient who died three days after operation was a very desperate case on admission, there having been absolute constipation for five days and vomiting of all the food This patient ceased vomiting after the operation but had evidently passed the possibility of recovery before operation, the fourth case was a prostrated, premature baby which had practically no chance from the beginning It died about twelve hours after operation Necropsy showed hypostatic congestion of the lungs, nephritis and colitis The fifth died three days after operation, in spite of the relief of vomiting, of general weakness Of the eleven patients who recovered, two died subsequently, of other conditions The first died six weeks after the operation of acute enterocolitis All the symptoms of pyloric stenosis were relieved by the operation and the case was a favorable one for complete recovery until the intestinal infection developed The second patient died of pneumonia and empyema about a year after the operation The relief of the pyloric obstruction had been complete and recovery perfect At 14 months of age he appeared to be a normal baby At necropsy the pyloric enlargement was found to persist although the ratio of its size to that of the neighboring intestine was slightly smaller The remaining nine patients are alive and well, apparently suffering no ill effect from their pathologic condition or from the operation

69 Coccidia in Subepithelial Infections of Intestines of Birds P B Hadley Providence, R I —p 73
70 Bacterial Disease of Wragg Cherry W G Sackett Fort Collins Colo —p 79

68 **Influence of Milk on Intestinal Flora** —The most important factor in determining the character of the intestinal flora according to Hull and Rettger is the diet Lactose, milk and mixed grains (wheat, oats, etc) are specific articles of diet which exert such an influence Lactose, when fed in sufficient quantities (2 to 3 gm daily), brings about a complete transformation of the flora of white rats within two to three days, milk requires a longer time, and does not bring about a complete change Milk and lactose together form the most practical and effective diet, at least for man Grain feeds tend to increase the number of aciduric bacteria, but their influence is comparatively small Milk undoubtedly owes its beneficial action to the lactose which constitutes almost half of the solid matter present The explanation of this action must lie in the fact that the lactose is absorbed slowly from the intestine On several occasions it was found by the authors in the feces of rats that had been supplied with it as a part of their diet The raw grains are also probably acted on slowly, or at least some of the intermediate carbohydrate products are not immediately absorbed Bread, on the other hand, which contains cooked starch does not foster the development of the aciduric bacteria, because it is digested quickly, and no available sugar remains in the intestine long enough to be attacked and utilized by this group of bacteria

Meat or other high protein diet increases the indol-producing bacteria and other organisms of the so called putrefactive" type, cornstarch appears to foster the amylolytic group of intestinal organisms, while in a few experiments grain feed seemed to favor the development of what appeared to be fusiform bacilli The reaction of the intestine remained independent of the character of the intestinal flora The acidity was highest in the duodenum, as a rule, and lowest at the ileocecal valve

75 Case of Epidermolysis Bullosa Showing Loss of Elastic Tissue in Apparently Normal Skin R S Weiss, St Louis —p 26
76 Histopathology W J Heimann, New York —p 28

71 **Rare Form of Scleroderma**—The scleroderma in Ravogli's case, he says, was probably due to peripheral neuritis The system was affected by a form of diathesis, which had disturbed the equilibrium of the internal secretions, a sudden change of temperature due to exposure to wet and cold acted as a determining cause

74 **Elephantiasis Nostras**—A large majority of the cases of elephantiasis nostras, Elliott says, are due to the streptococcus of Fehleissen The primary changes are in the blood vessels rather than in the lymphatics The secondary changes are lymph stasis, edema, a marked hypertrophy of collagen with an infiltrate of small round cells and some polynuclear leukocytes Leprosy and acute scleroderma are to be considered in the differential diagnosis The streptococcic origin of the disease suggests that the local measures might well be augmented by antistreptococcic serum in the treatment of the disease

87 Id N E Williamson, Stockton, Calif—p 268

77 **Application of Typhoidin Test.**—A survey of the percentage of positive results obtained by Gay and Lamb in a study of 154 individuals shows that 75 per cent of those individuals that had recovered from typhoid (twelve) gave a positive reaction The negative reactions bear no relation to *the date of the* antecedent disease, since two cases twenty-two years previously were both positive From 75 to 40 per cent of those that had been vaccinated against typhoid (121) also reacted positively and in general in decreasing correspondence with the lapse of time since immunization Of twenty-one presumably normal individuals, three, 14 28 per cent, gave a positive typhoidin reaction Whatever may be the eventual understanding of a positive typhoidin test, the authors point out that use of its absence as an indication for revaccination certainly errs on the side of safety in detecting those individuals who in spite of typhoid vaccination do not show indications of a reaction to the typhoid bacillus, and who are, therefore, presumptively those particular individuals who under ordinary conditions of infection will be found to be the least protected ones

79 **Immature Polynuclear Leukocytes**—The presence of a high percentage of immature polynuclear leukocytes in the circulating blood (Arneth's "shift to the left"), Burgess *states* is evidence of excessive loss of polynuclear leukocytes from the blood stream, and an attempt on the part of the bone marrow to make good the loss It does not indicate toxemia nor is it an index of the patient s resistance to infection Leukocytosis, on the other hand, is evidence of toxemia and of direct stimulation of the bone *marrow* by certain toxins A moderate leukocytosis may exist without causing an appreciable change in the Arneth picture In *pulmonary tuberculosis* the demand for leukocytes indicated by a "shift to the left means necrosis and *extension of* the lesion In early stages of the disease this may be *of considerable* value in immediate prognosis and *even at times, in* diagnosis In advanced disease which is slowly progressing, as the demand for leukocytes apparently varies from time to time, the count appears to be useless in estimating the prognosis *In rapidly* progressing tuberculosis the unmistakable clinical evidence of activity renders the study of the blood picture superfluous In nontuberculous disease the evidence of excessive mobilization of leukocytes may be of value in doubtful cases to determine the presence of large collections of pus

80 **Simple Method of Plotting Charts**—The salient features of the method described by Williams are The printing on standard sheets of cross section paper all the fixed words and characters which will be common to all charts This usually can best be done by having them first drafted, and zinc etchings and plates or electros made therefrom The printing on gummed paper of all the common words and characters which the plotting of a given set of data will require These to be of the proper size and spacing to fit in the chart so as to give uniformity The printing of several types of cross hatching on gummed stock so that it may be similarly used The use of a photographic trimming board to smoothly and correctly cut the words characters and hatching used and the attachment thereto of a scale to facilitate calculations and to *minimize* errors

83 **Blood Pressure in Aged**—There were 100 women and fifty men examined by Bowes in this series The systolic and pulse pressures increased to the age of 85 and then decreased The diastolic pressure did not vary much after the age of *70* The blood pressure was higher in women except after the age of 90 There were a few who had very high blood pressures without symptoms They were going about their everyday duties in apparently perfect health There were some who simply complained of morning headache, slight vertigo, numbness or tingling of the hands and feet A third group presented the more severe symptoms of nephritis, aortic regurgitation, cerebral hemorrhage and arteriosclerosis There were twenty-two who had systolic pressures of 200 mm of mercury or over Thirteen had arteriosclerosis alone, three had cardiac lesions, two had nephritis, two had cerebral hemorrhage and cardiac lesions one cerebral hemorrhage and one nephritis and a cardiac lesion The highest systolic pressure was 270 mm of mercury This was a case of nephritis There were twenty-eight who gave diastolic pressures of 100 or over Sixteen had arteriosclerosis alone Seven had cardiac lesions, two had cerebral hemorrhage and a cardiac lesion, two cardiac *lesions* and nephritis and one had cerebral hemorrhage There were thirty who had pulse pressures of 100 or over The *highest* pulse pressure was 150, observed in a case of aortic regurgitation Sixteen had cardiac lesions, seven arteriosclerosis alone three cerebral hemorrhage, three nephritis and one had nephritis and a cardiac lesion All cases *of nephritis had* very high blood pressures The systolic, diastolic and pulse pressures were high in all cases of cerebral *hemorrhages* A low pulse pressure was associated with myocarditis or a *failing* heart, and a sustained pulse pressure of 100 or over usually resulted in myocarditis or a failing heart In most cases of bronchitis there was a failing heart with lowering blood pressure Obesity did not seem to influence *the blood* pressure

90 **Modified Method in Tuberculin Therapy**—The method described by Meyer consists of the simultaneous *administration* of three *different* tuberculins, namely, Koch's old tuberculin (T O) Koch's *bacillary* emulsion (B E) and Denys' bouillon filtrate (B F)

concludes that unless one knows how serum has been stored the putting on the label of a time expiry limit tells nothing and may lead to a false sense of security Kept under similar conditions, tetanus antitoxin loses its strength at about the same rate as diphtheria antitoxin The loss which occurs on keeping is in the number of units only The quality of the antitoxin remains the same, but the quantity is less This decrease can easily be remedied by giving larger doses

11 **Death After Salvarsan**—Wadia's patient was given 0 5 gm of salvarsan intravenously He died thirteen days afterward After a severe illness the symptoms suggesting acute yellow atrophy or phosphorus poisoning, but both were negatived by the fact of there being enlargement of the liver throughout, and also as to the former by the absence of leucin and tyrosin in the urine Wadia suggests that there must have been a storage of arsenic in the liver giving rise in all probability to acute fatty degenerative changes in the cells

3 **Treatment of Malaria by Tartar Emetic**—An apyrexial case of malaria showing numerous crescents in the blood treated with tartar emetic intravenously is cited by Rogers On the fourth day 4 cg of tartar emetic were given intravenously, 8 cg on the fifth and eighth days, respectively, and 12 cg on the eleventh day A case is cited of acute malignant tertian infection yielding to quinin, with subsequent appearance of numerous crescents, which disappeared after two intravenous injections of 8 cg tartar emetic, one on the second and one on the ninth day Rogers is of the opinion that quinin should be used to check the malarial paroxysms, while tartar emetic should subsequently be given intravenously, in the hope that it may prove of value in destroying the extracorpuscular stages of the malarial parasites, and so prevent relapses, and greatly lessen the infectiveness of the patient to malaria-bearing mosquitoes, by killing the crescent of the malignant tertian variety and the corresponding resisting forms of the other types of malaria Two additional cases are cited

6 **Keeping Qualities of Therapeutic Serums**—The question of the loss of antitoxin which occurred in samples of diphtheria antitoxin which had been in commerce for various periods was investigated by MacConkey The average period during which these serums were on the market was about two and a half years, and the average loss in unitage during that period was about 23 per cent, or about 10 per cent per annum Nothing is known about the conditions under which these serums were stored while in commerce, but it is obvious that the rates of deterioration varied greatly MacConkey

concludes that unless one knows how serum has been stored the putting on the label of a time expiry limit tells nothing and may lead to a false sense of security Kept under similar conditions, tetanus antitoxin loses its strength at about the same rate as diphtheria antitoxin The loss which occurs on keeping is in the number of units only The quality of the antitoxin remains the same, but the quantity is less This decrease can easily be remedied by giving larger doses

11 **Death After Salvarsan**—Wadia's patient was given 0 5 gm of salvarsan intravenously He died thirteen days afterward After a severe illness the symptoms suggesting acute yellow atrophy or phosphorus poisoning but both were negatived by the fact of there being enlargement of the liver throughout and also, as to the former, by the absence of leucin and tyrosin in the urine Wadia suggests that there must have been a storage of arsenic in the liver, giving rise in all probability to acute fatty degenerative changes in the cells

46 Gas Gangrene Statistical Study G Gross—p 586
47 Operative Cure of Cicatricial Stenosis of the Larynx E J Moure—p 591

38 **Chloridimeter**—An instrument for bedside use is described with which the chlorid content of the urine or other fluid can be easily estimated with the usual chemical tests The chloridimeter is a glass tube, graduated in two divisions The tube is filled to the lower mark U with the urine and then to the mark R with the reagent They are mixed by reversing the stoppered tube a few times The tube is graduated from 1 to 20 above the mark R The second reagent (29 075 gm silver nitrate and distilled water Q S for 1,000 gm) is added a little at a time It tints the fluid red but this disappears as the contents are mixed By adding more and more the red tint becomes more pronounced and more durable The figure marked at the point reached by the fluid when the tint has become stable is the index of the chlorid content in grams per liter of the fluid being analyzed The first reagent is a mixture of 2 gm potassium bichromate, 3 gm acetic acid, 10 gm sodium acetate and distilled water Q S for 1 000 gm The same tube is graduated, besides, like the Esbach tube and is used in the same way to determine the albumin content (See abstract 43 below)

39 **Erythematous Lupus**—Gaucher presents evidence to show that this affection may be of purely tuberculous origin, or due solely to inherited *syphilis*, or it may be of tuberculous origin on a soil of inherited syphilis

42 **Welfare Work for Young Children, and Infantile Mortality in Paris District**—Pinard reviews the work that has been done to promote infant welfare during the second year of the war, devoting over forty pages to the various measures enforced and the statistics of the last three years They

show that 50 per cent more children were abandoned in 1916 than in 1914, while the number of births was 50 per cent less The high wages paid in the munitions factories he regards as responsible in large measure for this state of things, and he declares that the only remedy is to forbid factory work for every pregnant woman, every nursing mother, and every woman who has borne a child within six months The infant mortality under 1 year of age is lower than in previous years

43 **Chloridimeter**—Achard describes perhaps the simplest form of chloridimeter and emphasizes the advantages of bedside examination of the urine which he has been preaching, he declares, for fourteen years His chloridimeter is a test tube and he uses always 3 drops of the 20 per cent solution of potassium chromate and 5 c c of the standard solution of silver nitrate The urine is then added until the reddish brown tint veers to a clear yellow The tube is graduated to show the amount of urine required for this color reaction By thus modifying the usual technic, letting the urine be the variable quantity, the test is rendered much simpler and much more convenient, he says, without detracting from its reliability The urine can be diluted if exceptionally concentrated or the nitrate solution can be diluted if the reverse prevails, calculating to allow for this (See abstract 38 above)

44 **Venereal Disease After Two Years of War**—Gaucher and Bizard say that just before the war, in a series of 3 000 patients in their service, 10 per cent were syphilitic In the first sixteen months of the war this proportion had increased to 16⅔ per cent, and in the last eight months to 25 per cent of 2,300 patients This last series of 600 syphilitics includes 219 civilians, thirty-seven under 20 years of age, and fourteen between 50 and 59, with one each of 64 and 66 Among the soldiers those over 25 furnish the largest contingent Among 222 women with recent syphilis during the first eight months of 1916 more than two thirds were married, and in a large proportion of cases the first symptoms were noted soon after the husband's brief visit home A third of these women were over 30 years old, further testimony to the probability of infection having occurred under legitimate conditions

Gaucher emphasizes also the extraordinary prevalence of gonorrhea in both men and women and expatiates on the necessity for enlightening the public as to its dangers and last but not least, on the necessity for teaching physicians to diagnose and treat it properly He has been appalled at the ignorance of the dangers of venereal disease which has been revealed by inquiry among the young men examined A number of instances are cited showing further that syphilitic eruptions and other lesions in both men and women had long been given futile treatment on a mistaken basis, throat lesions, leg ulcers, alopecia which subsided at once under specific measures The negative statements of patients should never be heeded He insists that every physician should take a course of training in some service for syphilography, especially now that there is reason to fear that syphilis is going to be carried into the remotest villages He pleaded with the authorities a dozen years ago to have a course in skin diseases and syphilis included in the fourth year of the medical course All agreed with him as to its advisability, but nothing was done he remarks, "as it is the custom in France to take no steps to prevent evil and to wait until it is done before seeking to remedy it" He adds that the war alone is not responsible for this increase in syphilis, it has only precipitated it

57 Recent Research on the Heart (Neuere Arbeiten uber Herzdiagnostik mit bes Berucksichtigung der praktisch verwendbaren Methoden) F Geppert—p 1298

53 **Ulcerative Colitis**—Ehrmann discovered some connection with dysentery in all but one of his cases of ulcerative colitis Either agglutination tests, the anamnesis or the necropsy findings gave conclusive evidence in this respect In several of the cases blood had long been passed in the stools at certain periods In some of the cases the infection had been mainly with the Flexner or Y bacillus, and yet the suppurating and ulcerating colitis was as grave as in the cases traceable to true dysentery

54 **Making a New Finger**—Neuhauser extols the advantages of a method with which a strip of a rib is transplanted into a fold of abdominal skin, and this in turn is sutured to the stump of the lost finger The hand can thus be fastened to the abdomen with the minimum of discomfort, while the results when the new finger was cut away from the abdominal wall were satisfactory in the case described, with illustrations

55 **Leukocytosis with Internal Hemorrhage**—Dold has confirmed on dogs and rabbits the rise in the numbers of leukocytes when internal hemorrhage has occurred This leukocytosis is manifest even with relatively slight internal hemorrhage It reaches its height in from eight to twenty-four hours, and has entirely subsided by the end of the fourth day He explains this leukocytosis as due to absorption of leukocyte-attracting products from the disintegration of albumin in the extravasated blood He thinks that it is destined to be quite an aid in diagnosis of internal hemorrhage

56 **Treatment of Meningitis**—Muhsam states that the mortality was 56 per cent in his numerous cases of epidemic meningitis in which intraspinal serotherapy was applied by the usual technic On the other hand it was only 5 per cent in the numerous cases in which daily lumbar puncture was done, withdrawing large amounts of fluid, up to 100 c c at a time He never witnessed any serious mishaps from it Mixed infection was quite common He adds that he is not allowed to give his figures, but that the numbers are large enough to warrant decided statements as to the value of thus evacuating the noxious fluid in these cases

58 **Coordinated Reflexes**—Bohme's experience has apparently demonstrated that the motor reflexes in the legs are alike in man and in animals, the coordinated reflexes in particular A particularly instructive case of myelitis is described which left the boy of 8 with complete paralysis of the left leg and also of the right except that it can be flexed a very little at the hip There is also paralysis of the rectum and bladder sphincters This condition has persisted for five years to date The tendon reflexes are exaggerated, and there are occasionally involuntary movements of the legs On stroking the sole, the hip and knee become flexed, with dorsal flexion of foot and toes, and this same coordinated reflex movement of whole sets of muscles can be elicited when the skin of the leg or of the lower abdomen is irritated With gentle stroking the reverse reflex movement is elicited A strong stimulus causes flexion a weak stimulus extension The extension reflex is tonic, the limb remains in the extension position even when it has been passively induced The other leg becomes slightly flexed as the one leg becomes extended, and vice versa Eliciting with strong irritation the flexion reflex in one leg induces extension in the other With the patient lying on his back, both legs fully extended, application of the electric current to the sole of one foot causes flexion of this leg and a trifle later, of the other also With both legs flexed, gently stroking one sole causes rapid and extreme extension of both legs The crossed and double reflex movements and coordinated reflexes observed in this case throw light on the mechanism of crippling contracture, etc They also suggest treatment of paralysis by eliciting coordinate movements instead of merely stimulating the separate muscles Bohme suggests practicing the limb with reflex flexion and contraction Study of the arm reflexes in the animal kingdom has shown that those which are no longer needed for man have been lost In four-footed animals the front legs require the same reflex phenomena as the hind legs, but in man, as he does not use his arms in walking, the arm reflexes differ essentially from the leg reflexes There are no crossed reflexes in the arms, while the leg reflexes in man seem to be identical with those in animals, and their retention indicates some biologic importance

62 **Organ Therapy of Disease of Endocrine Glands**—Nowaczynski investigated in particular the elimination of uric acid in seven cases of exophthalmic goiter, dystrophia adiposogenitalis or Addison s disease, under organ therapy No essential influence on the elimination of uric acid under these conditions could be detected In a few cases there was increased elimination, but the material is too small for conclusions

Medizinische Klinik, Berlin

71 Diagnosis of War Wounds of the Abdomen (Diagnostik der Bauchschusse) K Hanusa —p 1284
72 Optochin in Pneumonia A Stuhmer —p 1286

68 **Diabetes in Children**—In the course of the last three years Kleinschmidt has had fourteen diabetic patients between the ages of 2 and 14 years, nine boys and five girls Only two of the children were from well-to-do families and only one was from a Jewish family In five of the cases the diabetes was kept under control and the children look well, they have been under observation for from three to twenty months In two other cases the diabetes was of a moderately severe type, but in the seven others it was very severe In children the transition from the mild to the severe type occurs more rapidly than in adults In some of the cases the diabetes had not been recognized until after this transition had occurred There was a history of diabetes in the progenitors in two cases and of obesity in one Treatment has to be strictly individualized as the key to success is quantitative regulation of the diet calculating at 70 the calories required for a year old child and 35 calories per kilogram for an adult

For the qualitative regulation he calculates 2 gm albumin per kilogram for older children and 3 gm per kilogram for younger children, giving it in the form of meat, egg and cheese, with abundance of vegetables and fruit and at first 100 gm bread or potatoes or oatmeal, making up the rest of the calories with fat, preferably butter When the child is taking this diet regularly, it is easy to determine its tolerance of carbohydrates by testing the limits of tolerance This is best done in an institution, the limit once established, the treatment of the mild types can be continued at home under regular control of the urine One girl of 6 was able to take, along with the vegetables and fruit 150 gm bread and 100 gm potato, another of 7 takes 30 gm oat flakes, 50 gm bread and 50 gm potato Others have been able to bring the tolerance to a high point There was no glycosuria in one girl of 11 even after test ingestion of 420 gm wheat rolls with 50 gm grape sugar

The children seemed to be thriving after the tolerance had been determined and the level kept below this They attended school part of the time and stood well in their studies Some of them increased in weight by several pounds, but two showed no increase, and the temperature was sometimes inclined to be subnormal But none of the children lost the tendency to glycosuria, it returned on the slightest provocation even after weeks or months, brought back by a fright, disappointment about a journey, or a bad school report but most frequently by some slight intercurrent catarrhal affection, parotitis or diarrhea It was easy to restore the tolerance again, but the accumulation of such disturbances must gradually permanently reduce the level of tolerance Hence a tendency to even slight catarrh of the upper air passages must be regarded as a serious complication for diabetes in children In three of his cases measles had a decidedly unfavorable effect, in one the diabetes was first discovered after measles In a case reported by Naunyn, varicella entailed fatal acidosis, and in Starck's case whooping cough had this effect, but in one of Kleinschmidt's cases the girl of 7 passed through severe hemorrhagic uremic nephritis without return of the glycosuria This child had a suppurating skin affection, besides the diabetes

In the severe forms, vegetable days and oatmeal days sometimes prove of benefit, but the oatmeal failed completely in the case of one child between 2 and 3 He gave sodium bicarbonate or sodium or potassium citrate whenever the urine was found acid The acidity of the urine is a simple and exact gage of the acidosis, and thus of the danger threatening the child In six of his cases it proved impossible to render the urine alkaline, even with 40, 60 or 80 gm of the alkali, and coma soon followed In this stage no influence was apparent even from intravenous injection of a 5 per cent solution of sodium bicarbonate Aside from the alkali, he knows of no effectual drug treatment of diabetes Whether diabetes is liable to develop later in life when children have shown alimentary glycosuria or transient glycosuria during an infectious disease or as a symptom of myxedema, is still a question He has so far seen no tendency of the kind in cases long under observation

74 **Intragluteal Injections of Blood in Secondary Anemia** —Kohler has only two cases to report, but the benefit was so prompt and permanent and the technic so simple that he commends the measure for general adoption No attempt was made to defibrinate the blood The donor was the sister in one case A single injection answered the purpose here, the reds had dropped to 1,188,000 and the hemoglobin to 20 per cent after constant losses of much blood at the first menstruation By the fifth week after the intragluteal injection of blood the figures were 4 320 000 and 65 per cent The other was a maternity case with septic streptococcus endometritis reds 1 100 000 hemoglobin 15 Eight injections were made at four-day intervals to a total of 150 c c of blood In two months the reds ran up to 3 276 000 the hemoglobin to 50, and the improvement progressed afterward

76 **Whooping Cough** —Doernberger remarks that nothwithstanding the recommendations by the manufacturing chemists of dozens of remedies ending in in" on" and ol claimed to be specifics for whooping cough with testimonials as to their efficacy signed by reputable physicians and distributed broadcast still as ever the best means of relief, not cure is pure air free from dust and soot But this is hard to get in the homes of the poor, and health resorts are more and more disinclined to receive whooping cough cases to say nothing of the danger of contagion of others in cars and trains on the way to health resorts He suggests as a useful measure that a certain part of some public park be fenced off for whooping cough children and their attendants Roof gardens have also been proposed He cites the placards in use in Havana to show that certain places regard whooping cough seriously The public health service there posts a notice on the bill boards stating that whooping cough is epidemic in a certain district and warning against it, especially for young children, also giving directions for the children affected The placard on the whooping cough house also gives directions for preventing contagion of others

77 **Necessity for Including Venereal Diseases Among those Requiring Compulsory Notification and Compulsory Treatment** —This communication was translated nearly in full for the Social Medicine and Medical Economics Department January 27, p 306 Zumbusch is professor of skin diseases and syphilis at the University of Munich and Dyroff is professor of state and constitutional law (*Staatsrecht*) there

Zeitschrift fur Tuberkulose, Leipzig

91 Cure of Lupus under Phototherapy (Beitrag zur Lupusbehandlung mit kunstlicher Hohensonne) W Kaufmann —p 370

88 **Detection and Treatment of Tuberculosis in Children** —Hollos emphasizes that the treatment of tuberculosis in children must include prevention of repeated infection as well as measures to strengthen the resisting powers besides systematic specific treatment Every child known to be exposed to tuberculosis can be regarded as already infected The more sensitive to toxic influences the child's organism, the greater the production of antibodies, and hence the tuberculous process does not spread so rapidly, but the various functional disturbances from the toxins are more pronounced Such children are frail but they may live their whole life without the tuberculosis becoming manifest Only when in consequence of unhygienic conditions, alcoholism, measles or pregnancy, the immunity is lowered is the tuberculosis able to get the upper hand Sad examples of this are found in the soldiers with previously latent tuberculosis who return from the front with pulmonary phthisis

Latent tuberculosis in children is often revealed by defects in development The previously normal appearing child begins to grow thin and pale the skin and muscles feel flabby and the bones are inclined to soften and bend The mind often develops precociously and the children are known as good scholars, while others are correspondingly backward Children with latent tuberculosis "catch cold" readily, eczema and pruritus are frequent and there may be periods of some difficulty in breathing with or without bronchial catarrh Pains at different points are also instructive, by simulating appendicitis they have been known to lead to an unnecessary operation Owing to the influence of the tuberculosis toxins on the genital organs the picture of puberty may differ entirely from normal These toxins can act on the glands with an internal secretion either to irritate them to exaggerated functioning or to inhibit their functioning which explains why one child may grow tall and spindling under their influence while another may be short and stout There may be extreme emaciation or there may be obesity, premature or long retarded puberty frequent profuse menstruation or the menses may not commence until the sixteenth or eighteenth year or later and then occur at long and irregular intervals In boys early and repeated pollutions and sexual nervousness at puberty should arouse suspicion of latent tuberculosis

All these disturbances in tissues and functions which are induced by tuberculous infection in the growing child form as a whole the clinical picture of Stiller s universal asthenia' Others call it the lymphatic temperament" All seem to regard it as an inherited congenital predisposition a sub standard constitution when in fact it is merely the sum total of the disturbances induced by tuberculous infection during childhood It is not a congenital anlage and an inherited body frame but it is the results of the insidious sapping of an acquired disease And this, he reiterates is under our control if we recognize and attack it early enough with specific treatment.

89 **Influence of Artificial Pneumothorax on the Blood** —Gutstein gives the minute details of his examination of the blood of twenty tuberculous patients being treated with induced therapeutic pneumothorax In favorable conditions the number of reds rapidly and materially increased and the hemoglobin percentage also increased, but more slowly, while the total white count was reduced but the lymphocytes and eosinophils increased in numbers These were the findings with a successful pneumothorax free from complications When there were complications, these changes were not observed or the reverse was noted the hemoglobin declining while hyperleukocytosis and lymphopenia developed These changes in the blood picture are instructive for the prognosis It should be guarded when the blood shows hyperleukocytosis with lymphopenia and the hemoglobin percentage is dropping

94 *Epidemic of Hemorrhagic Disturbances in the Troops on Active Service (Sindromi emorragiche ad insorgenza epidemica tra le truppe operanti) P D Siccardi —p 1605

December 24 No 103 pp 1617 1632

95 Epidemic Jaundice (Sull'eziologia dell'ittero epidemico) M Ascoli and S Perrier —p 1618

93 **Freezing Injuries**—Silvestri remarks that freezing injuries are the scourge of the troops in winter, and that every effort must be made to relieve at brief intervals the troops exposed to freezing temperatures, and have them move about as keeping still favors freezing Freezing of the first or second degree he has found always heals spontaneously, regardless of what local measures may be applied They may relieve the suffering however This is not always proportionate to the gravity of the injury but depends more on the man's sensitiveness to pain Everything should be avoided —bandages, etc —that tend to have the limb kept still Massage, possibly with some sedative salve, and movements—these are the sovereign means of cure, supplemented when needed by scarification of the blisters, application of an absorbing powder, an extremely light protecting dressing and raising the foot, if there is much edema with early active exercise The men should not be allowed to stay in bed during the day, movement is the best of all measures, and although it may be painful at first, it soon relieves the suffering and hastens the cure It is not enough to advise the men to keep up and about, they must be made to do it With freezing of the third degree, the dressing must also be light permitting ample access of air The limb should be raised but not covered Silvestri has found calcium salts very useful in treatment of severe freezing, with or without strychnin to improve vasomotor tonus Both should be given freely but he warns against giving antitetanus serum in case of freezing of the second and third degrees

94 **Hemorrhagic Affections in the Italian Troops**—Siccardi noticed last summer the epidemic appearance of a transient hemorrhagic diathesis among the troops serving at the highest altitude among the mountains Whatever affection the men might be having, a hemorrhagic character was strikingly evident Hemorrhagic scurvy formed 2 5 per cent of the cases, and a hemorrhagic parascurvy," as he calls it, formed 42 per cent The symptoms were the same as in true scurvy, but the general health was not impaired and in 29 per cent there was no stomatitis In 51 per cent of the cases there was typical exanthematous purpura The course in all the cases was benign Rest and dieting seemed to be all that was necessary Defective ventilation of the underground shelters, the cold and damp, wet feet, wet clothes, and the unbalanced diet easily explain the tendency to these troubles Rest dry warmth and change of diet soon restored normal conditions as a rule Bacteriologic tests were constantly negative except in a small group of 0 5 per cent who presented infectious hemorrhagic skin lesions with typhoid plus paratyphoid B in some cases Of the total number of men with this hemorrhagic tendency, 4 per cent were in the frozen limb group, weak but with no signs of sepsis

Pediatria, Naples

November 1916 XXIV No 11 pp 641 704

96 *Improved Technic for Intubation for Stenosis of the Larynx (Terapia delle stenosi laringea col metodo Bellotti Isonni modificato) L Leto —p 641

97 *Study of the Meningococcus in a Recent Epidemic of Meningitis (Comportamento morfologico e biologico dei meningococchi di Weichselbaum isolati durante l epidemia di meningite cerebro spinale scoppiata in Palermo nell anno 1915 1916) G Rutelli —p 650

98 Multiple Cerebral Tuberculomas A Corica —p 660

99 *The Hemolyzing Power of Certain Preparations of Antimony Used in Therapeutics G Caronia —p 667

96 **Improved Technic for Intubation with Stenosis of the Larynx**—With Leto's modification of the Isonni technic a long curved needle is worked through the thyrohyoid membrane a few millimeters below the margin of the hyoid The forefinger in the pharynx serves as guide to the needle and obviates any injury of the throat As the needle enters the throat it is drawn out through the mouth, and the long silk thread it brings with it is fastened to the laryngeal tube The tube is then easily introduced, aided by pulling on the silk coming out through the thyrohyoid membrane below The silk is then tied over a strip of gauze fastened like a cravat around the throat The tube is thus held firmly in place In one of the four cases of membranous croup described in which intubation was done by this technic, the tube had to be worn for six weeks The silk became macerated during this period but the procedure was easily repeated Nothing was found to suggest injury from the introduction of the needle, not even in the one case that came to necropsy

97 *Epidemic Meningitis*—Rutelli isolated Weichselbaum's meningococcus in thirty-seven of the nearly eighty cases of meningitis in a recent epidemic at Palermo, and he tabulates the morphologic and biologic peculiarities of the coccus and various features of the disease They demonstrate that the meningococci in various epidemics differ biologically in certain respects, showing that antiserums should be made from the special strain involved Only when the antiserum is made from the patients' own meningococci can it be depended on to be actually effectual in a given epidemic

99 **Correction of Hemolyzing Property of Antimony**—Caronia reports experiments which show that the pronounced destruction of the blood corpuscles liable with intravenous injection of preparations of antimony can be prevented by addition of salt He advises using a weak solution of the antimony preparation not over 0 5 or 1 per cent, in a 0 7 or 0 75 solution of sodium chlorid He experimented mostly with antimony and potassium tartrate

Policlinico, Rome

101 **Adiposis Dolorosa**—Alzona reports what he classes as a case of Dercum's disease in a soldier of 26 in the trenches During the last seven months small, very painful bunches have developed at various points under the skin, sparing only the face, upper arms and shoulders The appearance of each of the small swellings is preceded by a period of pain in the region and the pain persists The man tires readily and has pains in the lumbar and heart region His mother and one brother are epileptics and the man himself has had attacks and has passed through typhoid twice Epinephrin and atropin displayed slight if any action, but pilocarpin accelerated the heart beat and induced nausea general malaise and profuse salivation and sweating The metabolic findings under each of these drugs are tabulated and compared with those reported in other cases of the kind Few if any have been studied at such an early stage

102 **Pseudarthrosis of the Tibia**—The bones refused to heal after a fracture of the tibia just above the ankle in a girl of 6, and by the age of 16 the foot swung outward almost at a right angle from the leg The pseudarthrosis prevented any use of this foot The fibula curved but was intact A broad wedge was cut out of it and the tibia was resected above and below the pseudarthrosis With this operation approximately normal conditions were restored and the leg can now be used normally with a high sole He regards the trouble as of congenital origin as nothing else explains the complete lack of consolidation, and the fracture occurred with such slight trauma that it was almost spontaneous

THE RELATION OF THE ACID-BASE EQUILIBRIUM OF THE BODY TO CARBOHYDRATE METABOLISM

AND ITS APPLICATION IN HUMAN DIABETES *

FRANK P UNDERHILL
NEW HAVEN, CONN

A THE RELATION OF THE ACID-BASE EQUILIBRIUM TO CARBOHYDRATE METABOLISM

Under normal conditions the content of blood sugar may be regarded as one of the body's constants Transitory fluctuations may occur incident to ingestion of food, etc, but the variations encountered are confined within rather narrow limits The exact mechanism controlling the constancy of the blood sugar content is unknown It is well recognized, however, that a variety of agencies may temporarily throw out of equilibrium the blood sugar regulating mechanism producing either a state of hyperglycemia, with an accompanying glycosuria, or a condition of hypoglycemia in which sugar may or may not appear in the urine The introduction into the organism of epinephrin may be cited as an example of the type of agents leading to the development of hyperglycemia and glycosuria Phlorizin causes hypoglycemia with glycosuria, whereas hydrazin and phosphorus induce a diminished blood sugar content without the appearance of urinary sugar

The mechanism regulating the level of blood sugar is peculiarly sensitive to disturbances in the acid-base equilibrium of the body These may be manifested in either direction, namely, in conditions in which the equilibrium is overbalanced by excess of acid or deficiency of base (acidosis), or by circumstances leading to an overwhelming preponderance of base or temporary deficiency of acid (alkalosis) To avoid ambiguity it may be explained that the term "acidosis" is intended here to mean a disturbance in the acid-base equilibrium of the body whereby the introduction of, or the excessive production of, acid (ketogenic or otherwise) causes the withdrawal of base from the body The term "alkalosis" is sufficiently clear to need no special definition

Acid introduction or acid production in the body exerts a distinct influence on carbohydrate metabolism This assertion is supported by the observation of Elias[1] that the ingestion of acid by dogs and rabbits leads to hyperglycemia and glycosuria Elias[2] has also concluded that the so-called "hunger diabetes" of young dogs, as described by Hofmeister,[3] is in part, at least, a condition due to acidosis, as indicated by the lowered carbon dioxid content of the blood and of the alveolar air In human diabetes also it is conceded that acidosis arises This brief review of the literature on the subject makes it evident that the introduction of acid or the production of acid in the organism is associated with a disturbance of blood sugar content which is manifested in one direction, namely, blood sugar content is augmented

On the other hand, a state of alkalosis is likewise potent in exerting an influence on carbohydrate metabolism, but this action is contrary to that of acidosis That alkali introduction influences carbohydrate regulation in the body was demonstrated by Pavy and Godden,[4] who found that the glycosuria provoked by ether or chloroform disappears after the intravenous injection of sodium carbonate Given by mouth or intravenously, sodium carbonate will abolish the hyperglycemia of "hunger diabetes", and according to Elias,[2] the glycosuria will either entirely disappear or be greatly diminished After removal of the pancreas, sodium carbonate introduced into the blood stream of the dog causes a diminution of the sugar excretion [5] Murlin and Kramer[6] showed that under the influence of sodium hydroxid the respiratory quotient is increased in depancreatized dogs In agreement with this finding are the results of Kramer and Marker,[7] who have stated that "sugar retained when sodium carbonate is administered to depancreatized dogs is not stored as glycogen nor is it eliminated by way of the saliva or the gastro-intestinal tract" These observations[8] indicate that alkali introduction facilitates sugar combustion in the depancreatized dog

The explanation for the closely agreeing observations just cited probably lies in the effect which sodium carbonate exerts at times on the blood sugar content of normal animals The intravenous injection of sodium carbonate may cause, although not invariably, a marked diminution in the blood sugar content[9] of rabbits When blood sugar content is affected, the diminution is transient, the normal being regained within one or two hours Moreover, the hyperglycemia and glyco-

117 *Fibrositis in the Legs (Fibrositis extremitatum inferiorum) P Lorenzen —p 1193

117 Fibrositis in the Legs—Lorenzen has encountered comparatively frequently a typical clinical picture caused by infiltration of the connective tissue in the feet and also in the legs The tenderness and pain may interfere with the use of the leg The symptoms may resemble those from severe arteriosclerosis in the region The pains are increased by functioning, and they may spread upward even beyond the legs and there may be tonic contractions In children and young people functional disturbances predominate, either as a weakness or altered pose of the foot, with chilliness and sweating of the foot and other motor disturbances The fibrositis may be palpated not only at the point of greatest tenderness but elsewhere on that leg and sometimes on both The almost invariable valgus position of the big toe, or hammer toe, suggests that these deformities are always traceable to some form of this fibrositis The frequent association with flatfoot is also suggestive of a causal connection

The fibrositis may affect persons of all ages, and it is often mistaken for rheumatism, gout, varices, or merely flatfoot disturbance Treatment applied on these mistaken premises is futile, while prompt recovery is the rule under local palpation and exercise of the tendons and muscles involved A history of prolonged exposure of the feet to cold or dampness or overuse alone or in combination, can usually be elicited One of his child patients had been going barefoot during a long period of damp, bleak weather A constitutional predisposition to nervous and joint troubles was more or less manifest in every case Only a few had been relieved by heat and warmth, or by some special attitude of the foot The infiltration can be palpated at various points in the foot, as he describes in detail, mostly along the flexor brevis digitorum or the extensor tendons of the big toe Peritendinitis is the rule, and these changes can be traced for some distance A few times he found a diffuse chronic swelling running around the foot, the ankle and lower part of the leg The fibrositis may extend to the knee, and the veins are often varicose There may be pain on pressure of the veins but it can be traced to the tender muscle below Sometimes distinct nodules can be felt on the sole, below the tuberosity of the calcaneum Fibrositis in the neck shoulders, arms and lumbar regions is more common, but even here it is liable to be erroneously diagnosed and treated

THE RELATION OF THE ACID-BASE EQUILIBRIUM OF THE BODY TO CARBOHYDRATE METABOLISM

AND ITS APPLICATION IN HUMAN DIABETES *

FRANK P UNDERHILL

NEW HAVEN, CONN

A THE RELATION OF THE ACID-BASE EQUILIBRIUM TO CARBOHYDRATE METABOLISM

Under normal conditions the content of blood sugar may be regarded as one of the body's constants Transitory fluctuations may occur incident to ingestion of food, etc, but the variations encountered are confined within rather narrow limits The exact mechanism controlling the constancy of the blood sugar content is unknown It is well recognized, however, that a variety of agencies may temporarily throw out of equilibrium the blood sugar regulating mechanism producing either a state of hyperglycemia, with an accompanying glycosuria, or a condition of hypoglycemia in which sugar may or may not appear in the urine The introduction into the organism of epinephrin may be cited as an example of the type of agents leading to the development of hyperglycemia and glycosuria Phlorizin causes hypoglycemia with glycosuria, whereas hydrazin and phosphorus induce a diminished blood sugar content without the appearance of urinary sugar

The mechanism regulating the level of blood sugar is peculiarly sensitive to disturbances in the acid-base equilibrium of the body These may be manifested in either direction, namely, in conditions in which the equilibrium is overbalanced by excess of acid or deficiency of base (acidosis), or by circumstances leading to an overwhelming preponderance of base or temporary deficiency of acid (alkalosis) To avoid ambiguity it may be explained that the term "acidosis" is intended here to mean a disturbance in the acid-base equilibrium of the body whereby the introduction of, or the excessive production of, acid (ketogenic or otherwise) causes the withdrawal of base from the body The term "alkalosis" is sufficiently clear to need no special definition

Acid introduction or acid production in the body exerts a distinct influence on carbohydrate metabolism This assertion is supported by the observation of Elias[1] that the ingestion of acid by dogs and rabbits leads to hyperglycemia and glycosuria Elias[2] has also concluded that the so-called "hunger diabetes" of young dogs, as described by Hofmeister,[3] is in part, at least, a condition due to acidosis, as indicated by the lowered carbon dioxid content of the blood and of the alveolar air In human diabetes also it is conceded that acidosis arises This brief review of the literature on the subject makes it evident that the introduction of acid or the production of acid in the organism is associated with a disturbance of blood sugar content which is manifested in one direction, namely, blood sugar content is augmented

On the other hand, a state of alkalosis is likewise potent in exerting an influence on carbohydrate metabolism, but this action is contrary to that of acidosis That alkali introduction influences carbohydrate regulation in the body was demonstrated by Pavy and Godden,[4] who found that the glycosuria provoked by ether or chloroform disappears after the intravenous injection of sodium carbonate Given by mouth or intravenously, sodium carbonate will abolish the hyperglycemia of "hunger diabetes", and according to Elias,[2] the glycosuria will either entirely disappear or be greatly diminished After removal of the pancreas, sodium carbonate introduced into the blood stream of the dog causes a diminution of the sugar excretion [5] Murlin and Kramer[6] showed that under the influence of sodium hydroxid the respiratory quotient is increased in depancreatized dogs In agreement with this finding are the results of Kramer and Marker,[7] who have stated that "sugar retained when sodium carbonate is administered to depancreatized dogs is not stored as glycogen nor is it eliminated by way of the saliva or the gastro-intestinal tract" These observations[8] indicate that alkali introduction facilitates sugar combustion in the depancreatized dog

The explanation for the closely agreeing observations just cited probably lies in the effect which sodium carbonate exerts at times on the blood sugar content of normal animals The intravenous injection of sodium carbonate may cause, although not invariably, a marked diminution in the blood sugar content[9] of rabbits When blood sugar content is affected, the diminution is transient, the normal being regained within one or two hours Moreover, the hyperglycemia and glyco-

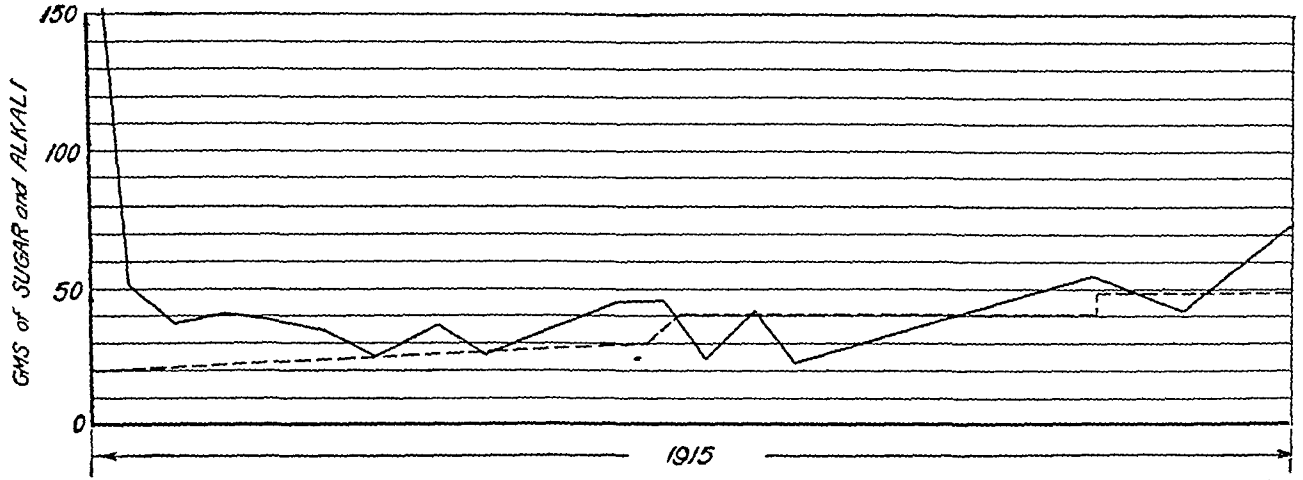
[9] Underhill Jour Biol Chem 1916 **25**, 463

suria provoked in rabbits by epinephrin[10] are both significantly decreased if sodium carbonate has been administered at suitable periods of time previous to epinephrin administration

The regulation of blood sugar content would thus appear to be associated in part at least with the equilibrium between acids and bases in the body Acid tends to increase blood sugar content, acid has an influence in causing sugar elimination On the other hand, base or alkali tends to reduce the blood sugar content These ideas fit in well with facts concerning other conditions associated with carbohydrate metabolism Underhill and Blatherwick[10] have shown that previous to the tetany provoked by removal of the thyroid-parathyroid mechanism, blood sugar content may be greatly diminished Calcium relieves the tetany and restores blood sugar to normal In the disturbance of carbohydrate metabolism induced by epinephrin, calcium[11] causes a distinct change in the character of the curve of hyperglycemia, and markedly increases the amount of sugar appearing in the urine under the stimulus of epinephrin administration In other words, calcium behaves in a manner analogous to hydrochloric acid Wilson[12] and his co-workers had previously found that prior to the onset of tetany after removal of the thyroids and parathyroids a condition of alkalosis develops The introduction of acid relieves the symptoms equally as well as calcium administration The period of alkalosis corresponds fairly well with the interval of low blood sugar observed by Underhill and Blatherwick In view of these facts, it is probable that the condition of alkalosis may be responsible for the accompanying hypoglycemia The resumption of normal blood sugar content is induced by introduction of either calcium or hydrochloric acid, which have a common behavior in increasing blood sugar content under appropriate conditions The introduction into the dog of the diamin, hydrazin, results in a transitory decrease in the percentage of sugar in the blood[13] with an accompanying increase *of the respiratory quotient* [14] At the period of hypoglycemia, the excreted urine exhibits a strongly alkaline[15] reaction, probably owing to carbonates



Influence of sodium bicarbonate ingestion on the glycosuria of a

These observations lead to the conclusion that a condition of acidosis facilitates the elimination of carbohydrate from the body, whereas in alkalosis there is a tendency to conserve carbohydrate

B THE APPLICATION OF THE IDEAS CONCERNING ACID-BASE EQUILIBRIUM TO HUMAN DIABETES

If the ideas reviewed above concerning acid-base equilibrium in its relation to carbohydrate metabolism are applied to human diabetes, one gains the following conception of its chemical pathology Without reference to what may initiate the abnormal condition, a state of acidosis unquestionably develops and must tend to become aggravated, if anything, by the characteristic acid-producing foods of the conventional diabetic dietary In general, meats and cereals are acid-producing foodstuffs, vegetables and fruits, on the other hand, usually yield an excess of base Those foodstuffs which are richest in base-producing substances are forbidden to the diabetic individual because they contain relatively large quantities of carbohydrates The conventional diabetic dietary, consisting largely of meats and other protein foods and fats, would therefore have a decided tendency to aggravate the condition of acidosis induced by the abnormal state From what has been pointed out already, it seems reasonable to conclude that anything which will counteract or neutralize the continuous stream of acid entering the body should benefit the individual One is led to ask, What influence would this have on the excretion of sugar if the organism were once saturated, so to speak, with alkali and enough alkali continually supplied to neutralize the exogenous and endogenous acid? These considerations have been put to the test in a human diabetic, aged 26 years, with a very severe type of diabetes

Case 1—A young university instructor had been aware of his condition for several months, and although he had received medical aid and was on a so-called "diabetic diet," his condition was steadily growing worse He first came under my observation, Jan 4 1915, and at this time was excreting more than 150 gm of glucose per day, although on a 'diabetic diet' The urine contained large quantities of acetone and diacetic acid, and the subject was losing weight rapidly The body weight, Jan 4, 1915, was 146 pounds

Dietetic Treatment—By restriction of the diet to the point at which little or no carbohydrate was consciously ingested *in accordance with the suggestions of Joslin's dietary chart*, the daily output of sugar was reduced to from 25 to 50 gm, acetone and diacetic acid always being present in relatively large quantities Sodium bicarbonate in small amounts was given for the purpose of neutralizing the ketogenic substances in accordance with the usual therapeutic practice After a year's interval, in spite of very stringent dietary restrictions, the sugar excretion suddenly increased to from 70 to 80 gm daily The progress of the subject during the period of a year may be seen from the chart

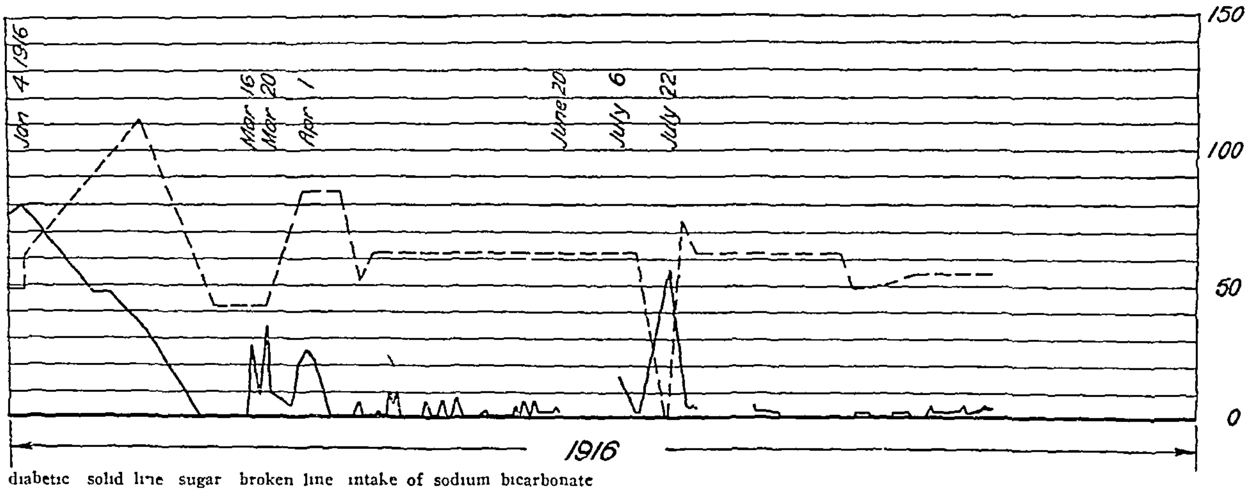
[15] Underhill and Baumann Jour Biol Chem 1916 **27** 151

The Influence of Large Doses of Sodium Bicarbonate on Sugar Excretion—At this period (Jan 4, 1916) of high sugar excretion, gradually increasing doses of sodium bicarbonate were given to a maximum of 120 gm per day This treatment resulted in *a gradual diminution of sugar output until the urine became sugar free* (see chart) The dosage of sodium bicarbonate was thereupon decreased at the rate of 7 gm per day until the intake amounted to 42 gm per day Under these conditions the urine remained sugar-free for a period of seventeen days (see chart), during which interval the food ingested was augmented to the point at which about 10 gm of carbohydrate in addition to that present in the previous strict diet were ingested daily Acetone and diacetic acid were *still present* but in greatly diminished amounts, and the urine was strongly alkaline in reaction The volume of urine voided daily varied between 2 and 3 liters

With the idea of determining the tolerance of the patient toward a large quantity of sugar, a portion of grapefruit was added to the diet The quantity of sugar ingested amounted to 26 gm As is apparent from the chart (March 16) an equivalent quantity of sugar promptly appeared in the urine but quickly fell to less than 10 gm March 20 a second sharp rise may be noted the sugar output being caused by *the patient breaking over his diet and eating* indiscriminately The third sharp rise (see chart, April 1) in the output of sugar is associated with a severe attack of bronchitis The patient was confined to his home for a period of thirty-one days during which it was deemed advisable to increase temporarily the intake of alkali This had as a result a drop in sugar excretion to the zero point From that period until June 20 the sugar output fluctuated from zero to 10 gm per day The break in the sugar curve represents a vacation period In the period just previous to the June vacation, no strenuous attempt was made to keep the urine sugar-free The larger figures represent either indiscretions in diet or are associated with particularly strenuous days in which nervous tension was unduly pronounced On his return from vacation in July (July 6), the sugar excretion was approximately 15 gm which by proper regulation of the diet quickly fell to 2 gm

The Influence of Alkali Withdrawal on Sugar Excretion—In order to determine the influence of the alkali therapy on the sugar excretion from a different point of view, the patient was maintained on a constant diet on which never more than 2 gm of sugar appeared in the urine, and the alkali was then gradually withdrawn As may be seen from the chart, *glycosuria steadily increased as the alkali was decreased, until at the period* (July 22) *when no alkali was ingested nearly 60 gm of sugar were excreted per day* During this interval the patient was obliged to lie down most of the time, owing to great weakness, and on one occasion had a "fainting spell" At the solicitation of the family the experiment was carried no further, *alkali was again administered, the diet remaining unchanged, and, as may be seen from the chart, the sugar excretion fell rapidly to the zero mark* The subject speedily regained his sense of strength and well being, which has been maintained to the present time (November 10)

The Degree of Acidosis of the Patient—During the autumn of 1916 the chart shows a slight upward tendency of sugar excretion This may be explained by the fact that the patient is receiving a relatively small alkali intake, 49 gm per day There is little doubt that with a larger daily ingestion of sodium bicarbonate the urine could be made sugar-free The main reason that the alkali intake has not been increased is that 49 gm of sodium bicarbonate just suffices to keep the urine near the point of neutrality When the alkali was entirely withdrawn a test was made to determine how much alkali was necessary in order to overcome the acidosis of the subject, that is, the amount of alkali sufficient to render the urine alkaline Ingested at seven intervals during the waking hours, 49 gm of sodium bicarbonate just yielded an alkaline urine This is the minimum amount necessary to keep the urine at the point at which it is either faintly alkaline or faintly acid to litmus When it is remembered that in normal man at most 15 gm of sodium bicarbonate are sufficient to render the urine alkaline, it is evident that in the present instance a severe acidosis is present Acetone and diacetic acid are always to be found in the urine, but not in large quantities



diabetic solid line sugar broken line intake of sodium bicarbonate

Body Weight—During the period of alkali administration *body weight of the subject has fluctuated between 124 and 135 pounds The attack of bronchitis referred to above* caused a loss of weight of about 10 pounds At present (November 10) the body weight is 131 pounds

Food Intake—Calculation of the food intake shows the patient to be receiving approximately from 15 to 18 gm of nitrogen and 2,400 calories

Method of Alkali Administration—Sodium bicarbonate dissolved in water is very likely to cause nausea and vomiting If the alkali is dissolved in a little water and ordinary carbonated water is added, the mixture may be drunk with no bad effects So far as can be discovered, the ingestion of large doses of sodium bicarbonate over a long period of time has caused no injury or untoward symptoms of any sort In order to keep a stream of alkali entering the tissues more or less constantly sodium bicarbonate is taken in seven equal doses at approximately equal periods during the waking hours The urine secreted during the night remains alkaline

THE INFLUENCE OF SODIUM BICARBONATE IN A MILD FORM OF DIABETES

The most striking effects of alkali administration in diabetes are encountered in the very severe cases, as might naturally be expected, because of the greater degree of acidosis. In patients with a well defined tolerance to carbohydrate, the influence of alkali treatment may be seen, however, and there is also some evidence of an increased tolerance under the treatment.

Case 2.—A Jewish woman aged 42, with a history of diabetes of several years' standing, for a period of at least two years had had her dietary arranged by me in such a manner that on a typical strict diabetic diet the urine became sugar-free. Acetone and diacetic acid were never present. With the addition of three thin slices of baker's bread (weighing approximately 15 gm each) the urinary sugar increased to between 2 and 3 gm. Four slices of bread during the day caused an output of between 18 and 21 gm of sugar.

Slowly increasing doses of sodium bicarbonate (up to 50 gm) on the strict diet plus three slices of bread maintained this patient sugar free for a period of two days at the end of which four slices of bread were given with an output of 5.4 gm of sugar. With five slices of bread the sugar excreted amounted to 6 gm. Six slices of bread caused a urinary sugar excretion of 6.8 gm—approximately one-third that usually put out on four slices of bread when no alkali was given. It is apparent from these data that the carbonate administration permitted a much greater tolerance than obtained when no alkali was given.

CONCLUSIONS

The ingestion of large doses of sodium bicarbonate has a marked influence in decreasing glycosuria in severe diabetes, and in maintaining the diabetic individual in a state of comparatively good health and vigor. This effect is ascribed to the neutralization of the exogenous and endogenous acid of the organism.

In mild diabetes there is evidence that carbohydrate tolerance may be significantly increased by large doses.

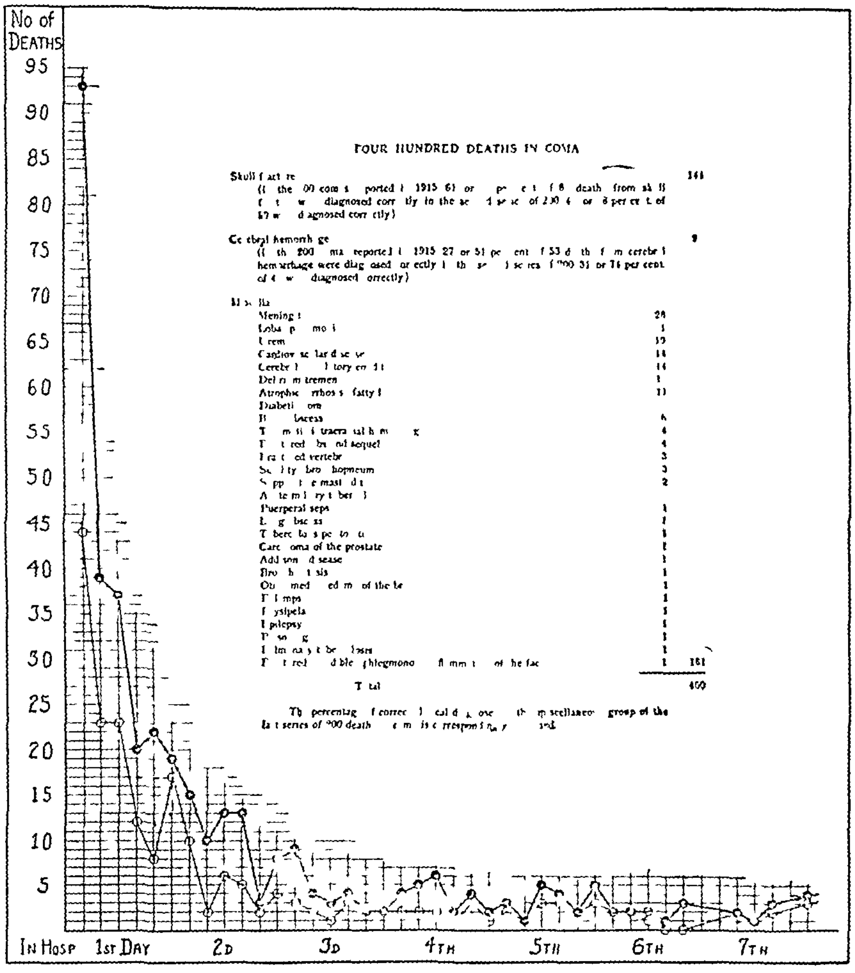
These conclusions are in harmony with experimental facts concerning the relation of acid-base equilibrium of the body to carbohydrate metabolism.

THE RELATIVE FREQUENCY OF THE VARIOUS CAUSES OF COMA*

WAYNE W BISSELL, M D
AND
E R LeCOUNT, M D
Resident Pathologist and Attending Pathologist, Respectively Cook County Hospital
CHICAGO

In 1915 we presented[1] the results of study of 200 deaths in coma, with special reference to the clinical diagnosis of uremia. During the past year we have been able to review the clinical records of an additional 200 persons dying in semiconsciousness or coma and, as in the first series, one of us (E R L) has examined all the bodies. In grouping these 400 deaths in coma, the possibility of aiding diagnosis of the various forms of coma, particularly in the practice of large hospitals receiving a great deal of so-called emergency work, has been kept in mind. We further believe that a presentation of the diagnosis efficiency of clinicians in the Cook County Hospital, and especially the improvement since the first report, will compare favorably with similar statistics from other large hospitals admitting many persons in some degree of coma.

As in our first consideration, we think the conditions are best represented by charts which take into account not only the number of deaths, but also the time allowed for clinical study and the number of correct diagnoses.



FOUR HUNDRED DEATHS IN COMA

Skull fracture		141
(Of the 200 comas reported in 1915 61 or [illegible] per cent of [illegible] deaths from skull fracture were diagnosed correctly; in the second series of 200 [illegible] or 8 per cent of 67 were diagnosed correctly)		
Cerebral hemorrhage		9
(Of the 200 comas reported in 1915 27 or 51 per cent of 53 deaths from cerebral hemorrhage were diagnosed correctly; in the second series of 200 31 or 76 per cent of [illegible] were diagnosed correctly)		
Miscellaneous		
Meningitis	28	
Lobar pneumonia	1	
Uremia	19	
Cardiovascular disease	14	
Cerebral [illegible] tory [illegible]	14	
Delirium tremens	1	
Atrophic cirrhosis, fatty liver	11	
Diabetic coma		
Brain abscess	6	
T[illegible] intracranial hem[illegible]	4	
[illegible] br[illegible] sequel	4	
Fractured vertebra	3	
[illegible] hopneum	3	
Suppurative mastoiditis	2

Puerperal sepsis	1	
Lung abscess	1	
Tuberculous peritonitis	1	
Carcinoma of the prostate	1	
Addison's disease	1	
[illegible] thrombosis	1	
[illegible] of the [illegible]	1	
T[illegible]mps	1	
Erysipelas	1	
Epilepsy	1	
Poisoning	1	
[illegible]	1	
[illegible] phlegmonous inflammation of the face	1	181
Total		400

The percentage of correct clinical diagnoses [illegible] miscellaneous group of the last series of 200 deaths [illegible]

Chart 1.—Correct diagnoses in 400 deaths from coma: heavy line deaths; light line number correctly diagnosed. In this chart twenty one deaths in coma are not plotted; they occurred as follows: 6 on the eighth day, 3 on the ninth, 4 on the tenth, 1 on the eleventh, 1 on the twelfth, 1 on the thirteenth, 1 on the fourteenth, 1 on the seventeenth, 1 on the twenty second, 1 on the twenty eighth, and 1 on the thirty first day. The clinical diagnoses were correct in eleven of these.

In Chart 1, the upper heavy line represents the number of deaths per four hour period, and the lower light line, the number of each of these groups receiving correct clinical diagnoses. Thus, it can be seen, ninety-three died within four hours after entrance into the hospital, and of these, forty-four, or 47 3 per cent, were correctly diagnosed clinically Thirty-nine died between four and eight hours after admission, and twenty-three, or 58 9 per cent, of these received correct clinical diagnoses Similarly, 230 died within twenty-four hours after admission, and of these, 127, or 55 2 per cent, received correct clinical diagnoses Twenty-four died on the third day of observation, and of these thirteen, or 54 16 per cent, received correct clinical diagnoses

---

* From the Cook County Hospital.

* A report made at the regular monthly staff meeting, April 13, 1916.

[1] Bissell, W. W., and LeCount, E. R.: A Consideration of the Relative Frequency of the Various Forms of Coma with Special Reference to Uremia, The Journal A. M. A., March 27, 1915, p. 1041.

The abrupt descent of both curves from the first four hours to the end of the third day is a most graphic expression of the high and rapid mortality of persons entering the Cook County Hospital in coma From the fourth to the thirty-first day, eighty-four died, and of these, forty-nine, or 58 33 per cent, were diagnosed correctly

The various causes of coma as determined by postmortem examination and the number of times each cause was found are tabulated in the center of the chart From analysis of this chart it seems reasonable to conclude that more than half of the persons entering the Cook County Hospital in coma die during the first twenty-four hours after admission, but few live longer than one week, and, in this series at least, the accuracy of the clinical diagnosis is little affected by the element of time

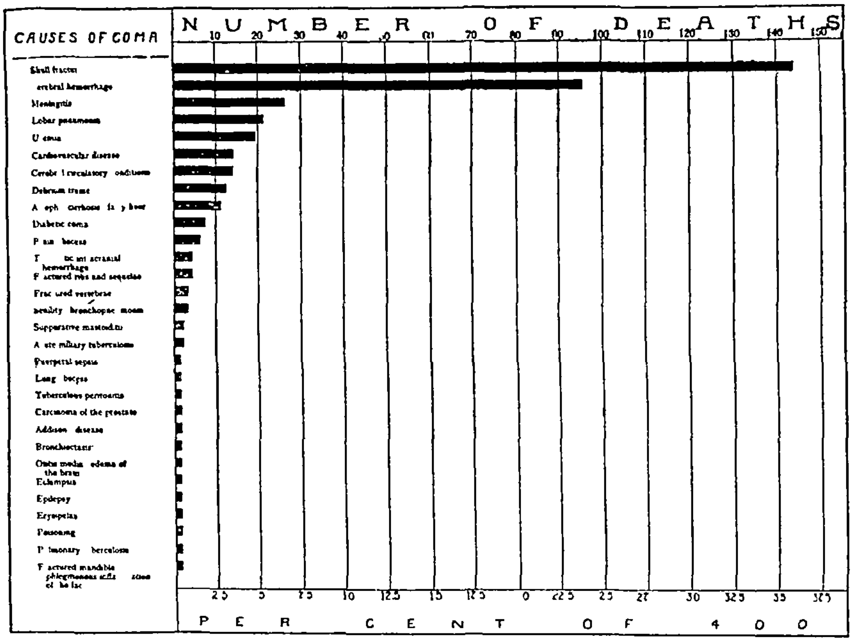

Chart 2 —Various causes of coma as determined by postmortem examination

In reading in Chart 1 the list of causes of coma with conditions which also produced death, it is noticeable that we have listed none of the common poisonings, such as the corrosives, illuminating gas or morphin Because either from history or obvious corrosion the vast majority of such persons enter the hospital with a diagnosis correctly made, we have omitted these instances of coma from consideration, and for like reasons we have not taken into account a rather large number of comas due to extensive and externally obvious injuries

In Chart 2 we have arranged in order of frequency the various causes of coma as determined by postmortem examination Reading from above downward, the lengths of the heavy black bars can be read in numbers, or, reading from below, in percentages of 400 Thus, 144, or 36 per cent, of these 400 persons entering the Cook County Hospital in coma which terminated fatally were comatose from skull fracture, ninety-five, or nearly 24 per cent, of these 400 from cerebral hemorrhage It is most interesting to note that less than 5 per cent of all these instances of coma were due to uremia, and it is similarly interesting to observe that, as a cause of coma, lobar pneumonia takes a position preceding uremia

It is also apparent that 239, or 59 75 per cent, of these deaths in coma were due to skull fracture or cerebral hemorrhage, and of these, 165, or 69 per cent, received correct clinical diagnoses The frequency with which skull fracture is observed with insignificant external injuries, and the common finding of bloody cerebrospinal fluid in persons comatose from spontaneous intracerebral hemorrhage lead us to believe that the diagnosis efficiency for skull fracture and cerebral hemorrhage is clinically very high

We wish to emphasize the value of such reviews as this to stimulate resident and attending members of staffs of large hospitals to make accurate, rapid clinical diagnosis

---

Passing of Tubercle Bacillus —And finally, however large you may make the tuberculous population of a given community if you subtract, as preventable causes those cases born of the preventable contagious diseases, especially those specifically liable to be complicated by tuberculosis, those cases developed because of drug, drink, or other abuses, those developed as the result of unhygienic conditions and unsanitary surroundings, those developed because of food deficiency or irregularity or of faults of metabolism, those developed and spread by wilfulness, carelessness or ignorance of known cases, those spread from unknown cases, those contracted because of the lack of those elements of culture demanded by modern society, those contracted because of the lack of proper quarantine of active cases, and those contracted from infected milk or other food supply your tubercle will have petered out and passed away The few remaining cases for whom one of these preventable causes could not be found will be so small as to be negligible And if the reduction has been accomplished up to this point who is there to say that it cannot be entirely eradicated? Why not? Even more virulent diseases, more sturdy bacteria, have been eradicated

There was a time when such diseases as smallpox, cholera, plague and the like had far larger populations and far greater death rates than tuberculosis—and they are gone Because the tubercle bacilli never attack the robust or unreenforced, every stride in the improvement of hygienic conditions, every improvement in physical condition and physical development, and every stride forward in preventive medicine will limit the range of operation of the tubercle bacillus Who can still say that tuberculosis is not the most preventable, the least contagious, and the most amenable to cure?—H M Friedman, *Journal of the Outdoor Life*, December, 1916.

Medical College 2960

HEREDITARY DEFORMING CHONDRODYSPLASIA—MULTIPLE CARTILAGINOUS EXOSTOSES

A REVIEW OF THE AMERICAN LITERATURE AND REPORT OF TWELVE CASES [*]

ALBERT EHRENFRIED, M D
Fellow of the American College of Surgeons, First Assistant Surgeon
Boston City Hospital Junior Assistant Surgeon, Children s
Hospital Surgeon Boston Consumptives' Hospital
Assistant in Surgery, Harvard Medical School
BOSTON

In the fall of 1914 a case of multiple cartilaginous exostoses, so called, appeared during my service at the Children s Hospital With the permission of Dr Lovett I investigated the case clinically and roentgenologically, and removed a strip of bone from across an affected epiphysis for pathologic study The results of this investigation were presented in an article[1] published in May, 1915

In reviewing the literature, I found that although the disease is generally considered rare, and textbooks in English give little or no place to it, more than 600 cases had been reported from all over the world, and about 350 articles had been written on the subject The American literature I found to be very scanty

As a logical sequence to my previous article, I proposed to discover if possible how frequent the condition really was in this country, and what its clinical and roentgenologic manifestations were Accordingly I present herewith (1) a review of cases hitherto reported in the United States, (2) a report of a series of personal cases, (3) observations as to the character and occurrence of the disease based on these cases, and (4) conclusions

REPORTED CASES

The first case reported in this country was by Gibney[2] In 1875 he showed a boy of 13 who presented the typical picture At 7 years he had been confined in bed for a long while with "acute rheumatism," and at 10 years he had recurring pain in his right hip Gibney[3] presented this patient again in 1879 At this time he showed several new exostoses, and some of those formerly present seemed to have increased in size

In 1876 in an article on the subject, Gibney[4] presented a family consisting of a Prussian of 34 who had many large irregular hyperostoses, with subluxation of one finger and left genu valgum Over some of the hyperostoses the skin was cicatrized, representing ulceration from friction The growths were said to have reached a maximum size at puberty since which time many were said to have decreased in size His father and brother were said to be affected, and his daughter of 11, son of 9, and daughter of 4 were presented as well defined cases This is the first family reported in this country, and it is interesting because in the first generation there is one person affected, in the second two, and in the third three

In 1889 Leidy[5] reported a case in an Irish girl of 25 who presented multiple bony tumors, those about the knee being unusually large, causing pain and interference in walking There is no statement concerning heredity

Wright,[6] in 1887, showed a boy of 11 presenting the typical picture

Davis,[7] in 1905, reported two cases, one a man of 53, no hereditary history ascertained, presenting typical knock knee, curved and shortened forearms with displacement of the carpi, subluxation of a finger, pes valgus, rosary and enlargement of the spines of the *seventh cervical and first and second thoracic* vertebrae He came under observation on account of suppuration of an exostosis of the femur This case is interesting because during a year, under the observation of Dr Davis, a small growth on the ramus of the left pubis diminished noticeably in size The second case was a child of 3, with rosary, knockknee, etc No family history was obtained

In the discussion of this paper, Dr H L Taylor reported a family in which the father was probably affected, a boy of 12, a girl of 10, and a boy of 8, definitely so A H Freiburg described a case in a man of 80, who was operated on for popliteal aneurysm caused by friction of an exostosis In this patient the family history went back three generations Dr D D Ashley reported a girl of 11 and a boy of 9 affected, with a history of the affection reaching back to include the mother, grandmother and great-grandmother

In 1907, Ochsner and Rothstein[8] reported an interesting case of intraspinal exostosis The patient was a man, aged 23, without known hereditary history, in whom the condition was noted at the age of 2, 108 exostoses were counted, including an unusual one on the left superior curved *line of the occiput* The patient stated that these exostoses grew at the same rate as he did until the age of 19, when they stopped At 14 he began to have incoordination of the lower extremities, which condition grew worse so that during the past year the upper extremities were involved and there was pain on the right side of the body on turning the head to the right Rothstein diagnosed an exostosis within the spinal canal on the right side, and at operation his diagnosis was confirmed and an intradural pediculated tumor, which was flattening the cord, was removed from the anterior aspect of the right lamina of the second cervical vertebra The operation was unfortunately followed by quadriplegia with loss of bladder and bowel function, from which condition the patient gradually improved, so that he was walking with crutches at the time of the report

Clark and Atwood,[9] the same year, in a series of interesting neurologic cases, reported one as "a case of multiple enchondroma, one of which is growing from the sella turcica, causing pressure on the pituitary body" The patient was a boy of 17 with spastic quadriplegia, the same one described later by Oberndorf

Withington,[10] in 1907, showed an Italian, aged about 35, who was suffering from acute articular rheumatism, multiple exostoses were found on examination, and were said to have existed since early childhood No history of heredity was made

Oberndorf,[11] in 1910, described in some detail the case already reported by Clark and Atwood The boy was of German parentage, aged 19 years No history of heredity was noted, but the father and mother were second cousins The condition was first noted at 4 years, and the mother said that many growths had appeared and vanished spontaneously One rapidly growing tumor over the precordium was removed at the age of 11 by McBurney, and the pathologic diagnosis of enchondroma was made The boy suffered from acute rheumatism at the age of 12 He had a scoliosis with some apparent kyphosis and forty palpable masses The hands and feet were increased in size and the finger tips were blunt and spadelike, suggesting acromegaly Oberndorf considered this due to a growth in relation to the sella turcica causing pressure on the pituitary body For the past three years the patient had suffered from a marked syringomyelia, and some months after his coming under observation died of inanition, complicated by bedsores

Coon,[12] in 1912, reported the case of a boy of 15 without hereditary history He presented an atypical picture The deformities affected particularly the right leg and arm The left limbs showed mild bony changes on Roentgen examination, but were practically without deformity In the fingers of both hands, roentgenoscopy revealed chondromatous masses involving the metaphyseal ends of the phalanges, in the right forearm the shortening appeared in the radius, rather than in the ulna, where it usually occurs The lower end of the radius showed typical broadening and striation of the metaphyseal extremity with distortion of the epiphyseal line The same was true of the right shoulder, knee and ankle

Boggs,[13] in 1913, reported the case of a man, aged 23, who was said to have been born with bony tumors, and whose father had bony tumors Roentgenoscopy revealed the characteristic clinical picture, with a normal sella turcica The patient had been blind for about a year, and the legs had become weak eight months before he came under observation There was moderate double optic atrophy The thyroid gland was not made out The case was reported as one of multiple congenital osteochondromas with thyroid atrophy, degeneration in the acoustic and optic nerves, and muscular atrophy

In 1913, Vaughan[14] emphasized the hereditary nature of multiple exostoses

Carman and Fisher, in 1915,[15] reported the case of a man, aged 23, in whom no heredity was ascertained It was noticed at birth that the arms were thick at the elbows and wrists The bony tumors were not particularly noticeable until the age of 8, when they began to grow, and continued to increase parallel to skeletal development until about 22, when growth ceased He came under observation on account of an irritation abscess over an exostosis on the clavicle He was 5 feet 9 inches tall, and showed bony growths generally distributed, including the jaw, costochondral junction (rosary), and scapulae He had scoliosis, relative shortening of the left arm and leg, moderate flatfoot, synostosis and clubbing of fingers and toes, and asymmetry of the toes An exostosis within the pelvis was felt by rectal examination The forearms were exceedingly deformed and short, the right showing the typical deformity in moderate degree and the left showing an exceeding degree of hyperostosis at the lower end of the shafts of the radius and ulna, with the hand dislocated inward and the upper end of the radius dislocated outward The ulna being extremely short, the length of the relatively long radius was taken up by a spiral twist of the radius about the ulna

Percy, in 1915,[16] reported a case of a boy of 17 of stocky build, in whom the first tumor was noticed at 4 years, and who presented growths on the upper arms, knees and legs All the joints were enlarged, and the bones of the hands and feet were short, stubby and nodular On the inner aspect of the right arm was a cauliflower chondro-osteoma the size of a cocoanut, which had grown markedly during the past three years This was removed by operation The boy's grandfather, who was born in Holland, was said to have been affected with the disease, and Dr Percy investigated his descendants He found that these numbered 113, of whom 26 were affected, 73 not affected and 14 unknown Of those affected, 22 were males and 4 females Transmission through affected males and females was about in the relative proportion of those affected, but in two cases the disease was transmitted through unaffected females This family tree, which includes four generations, is the first tree worked out in this country, and deserves further serious study

In the discussion of Percy's paper, Bevan stated that there were many cases on record in which multiple ossifying enchondroma had caused a spinal cord lesion Ochsner stated that when animals have these enchondromas, a large proportion of the offspring have the same form of tumors M L Harris described a typical case with generally distributed tumors There was a large growth about the lumbosacral junction with paraplegia Operative removal did not relieve the paralysis Bedsores and gangrene developed, and the patient died

In 1915 I presented a review[1] of the subject based on the study of about 600 cases reported in over 300 articles, and the particular pathologic study of a section removed from an affected epiphysis in a growing child I stated the belief that the disease was a distinct clinical entity, characterized by (1) the occurrence of multiple, more or less symmetric cartilaginous and osteocartilaginous growths within and on the skeletal system, generally benign, and resulting from a disturbance in the proliferation and ossification of the bone-forming cartilage, (2) the occurrence of certain typical distortions and deformities of the skeleton, and (3) the demonstration of inheritance in a large proportion of cases To avoid the confusion which exists at the present time as the result of the multiplicity of terms by which the disease is known, I suggested the descriptive name of hereditary deforming chondrodysplasia The review included a consideration of the terminology, occurrence and distribution, heredity, pathology, etiology, symptoms and complications, and treatment

Ashhurst,[17] in 1916, reported a series of thirteen cases Two had previously been reported by Dr Davis, and two Dr Ashhurst had not seen but reported from hospital records The first patient was a girl, aged 4 years, with typical deformities, including subluxation of the right radial head Case 2 was a man of 20 who presented ulnar deviation of the carpi Case 3 was a negress of 11 who had a short left forearm and double pes valgus Case 4 was a boy of 17, in whom the left knee showed outward bowing and relative increase in length Cases 5 and 6 were two brothers of 15 and 13 years, a younger brother was said to be affected Case 7 was a boy of 14, who had paralysis of the left ulnar nerve evidently due to pressure of the bony mass in the neck In this boy the midpoint was half way between pubis and umbilicus Case 8 was a man of 30, in whom the exostoses were first recognized a year before, following an attack of rheumatism Dr Davis in this case removed an exostosis of the left femur which was pressing on the sciatic nerve Case 9 was a girl of 7, Cases 10 and 11 were the cases reported by Dr Davis, Case 12 was a boy of 16, and Case 13 a man of 34

Marshall,[18] in 1916, reported a case in a young woman This patient will be described later (Case 10) [19]

PERSONAL CASES

Case 1—*History*—Miss B T, white, aged 11, entered the Children's Hospital, Nov 6, 1914 She was born in Beverly, Mass Father a French Canadian Father, mother and six other children living and well Detailed family history not obtained She was an 8 months' baby, fourth child and very diminutive Had breast milk for nine months followed by cow's milk and general table diet She has always been a weak child Began to walk at 19 months Whooping cough the only disease of childhood The deformity of forearm was first noticed at 6 months, it has become more and more prominent with time The flatfoot has been noticed since the child began to walk

Local Patient stands with slight left dorsolumbar scoliosis, with both shoulders thrown forward, a mild degree of knock knee on each side and the feet everted She walks with a rather uncertain gait, throwing her weight on the inner side of the feet, especially on the right The face is symmetrical, and shows no deformities Motions at the right shoulder joint normal The outline of the right elbow is distorted The forearm can pronate, supinate, flex and extend normally, but the head of the radius is subluxed outward and is greatly increased in size over normal Muscle power is good however Joint motions are free and there are no contractures Both bones of the forearm are unusually short and to palpation feel thicker than normal At the wrist, motions are free There are no contractures and muscle power is good The styloid process of the ulna is, however, at least 1 inch above the styloid of the radius and there is a distinct gap below the end of the ulna and the wrist joint The lower ends of both bones are oversize and there is a slight inward bowing of the ulna at about its lower third The left arm shows free motions at the shoulder, good muscle power and no contractures At the elbow the outline of the joint is distorted The head of the radius is subluxed externally and posteriorly, and is greatly increased in size The motions of flexion and extension, pronation and supination are free, and there are no contractures The forearm shows considerable bowing of both bones At the wrist the ulna is short, the styloid process being at least 1 inch above the radial styloid, the lower ends of both ulna and radius are increased in size Muscle power is good in all groups, and there are no contractures The hands are rather small, and the fists cannot be more than half clenched, on account of the obstruction offered by the enlarged extremities of phalanges and metacarpals At both hips the trochanters are on Nelaton's line, joint motions are free and muscle power good At the knees muscle power is good There are no contractures, and joint motions are free At the right ankle the internal malleolus is unduly prominent and the whole foot is held everted, joint motions are free, and muscle power good in all groups There are no contractures The left ankle is held somewhat in the same position as the right The internal malleolus is abnormally prominent There are no contractures and muscle power is good in all groups Reflexes Knee jerks present on both sides No clonus, Babinski, nor Oppenheim Right arm acromion to internal condyle 9⅛ inches Left, 9¼ inches

Left leg length, 28⅛ inches Circumference thigh, 12¾ inches, calf, 8¾ inches

Right leg length, 28¼ inches Circumference thigh, 13 inches, calf 8¾ inches

Roentgenologic Examination Cranium negative, sella turcica of normal size Thorax free, except for slight irregularities in lower ribs Marked lateral curve in lumbar spine Slight irregularities about sacro-iliac articulations Both ilia show a peculiar series of radiating striations about the crests Clavicles and scapulae are free, and the humeral heads show slight thickening The lower third of the shafts of the humeri show some deviation from normal contour The circumference is lessened, and the bone is bent The humeral condyles show mottling The ulnae are relatively short, bowed concave forward, and at the lower end present a large irregular bulbous enlargement, in which the epiphyseal line is lost The radii are straight, with the upper end dislocated outward and upward, so as to form a marked projection at the level of the outer condyle The lower end presents a similar irregular cystic like enlargement, but the epiphysis is present intact, though relatively small The entire carpal articulation is carried on the radius The distal ends of all the metacarpals and the proximal ends of the first two rows of phalanges show the globular striated enlargements referred to The femoral heads are squat and thick with flat epiphyses and prominent trochanters There is mild genu valgum in both legs, and the diaphyseal extremities of tibiae and fibulae are widened and irregularly striated, the fibulae are relatively short, so as to destroy the ankle mortise, and the tarsus is offset outward to create an extreme pes valgus The heads of the metatarsals, and the proximal metaphyseal extremities of the first phalanges show the globular vacuolated enlargements already seen on the fingers On the left foot the first and third digits show comparatively slight involvement, and are accordingly relatively longer than the other digits

The deformities in this case consist in a scoliosis, shortening and bowing of the forearms, ulnar deviation of the hands, dislocation of the heads of the radii, moderate knock knee extreme tarsal valgus, irregularity in length of toes, and shortness of stature There are no exostoses, few hyperostoses and the deformities are symmetrical

The roentgenograms were taken at the Children's Hospital

Case 2—*History*—Miss J W, white, aged 21, bookkeeper, was born in Boston of Jewish parents The father was born in Hungary, a tailor, of ordinary height He died of old age in Boston, at 82 His father died of tuberculosis No knowledge of deformities in family Mother born in Austria, living and well at 46 of ordinary height Her father living, 82 years old Mother died of old age at 75 No knowledge of deformities One brother died of hydrocephalus at 1½ years No other brothers or sisters The patient had measles in childhood, and nervous indigestion for several years Rheu matic pains in joints whenever exposed to a draft, or at a change of weather, for years but never so as to be confined to bed Menstruation at 14

---

[17] Ashhurst A P C Multiple Cartilaginous Exostoses (Hereditary Deforming Chondrodysplasia) with Notes of Nine Hitherto Unpublished Cases, Ann Surg 1915 **63** 167

[18] Marshall H W A Case of Multiple Cartilaginous Exostoses Am Jour Orthop Surg 1916 **14**, 346

[19] Since this paper was written A V Moschcowitz (Ann Surg 1916 **63**, 749) has reported a typical case in a man of 31 in whom an osteochondrome of the left femur of considerable size projected into the popliteal space, producing cyanosis and coldness of the extremity through interference with the blood supply

Physical Examination —I first saw her, May 7, 1915 I found her a bright looking girl of excellent mentality She had, in fact, won some distinction during her high school course She had been working steadily as a bookkeeper during the past three years The nausea had continued, but it was relieved by eating She had had no benefit from treatment and was convinced that it was purely nervous She had occasional twinges of pain in the joints Wrists are weak, particularly the left, so that at times she can hardly lift a sheet of paper She walks only with arch supports

She is short in stature, measuring 4 feet 8½ inches The middle point is half way between pubes and umbilicus The arms are noticeably short, the right reaching a third way down the thigh, and the left being shorter still Measurements from tip of acromion to the tip of middle finger are right 23½, left, 22¼ Musculature is good Both arms hyperextend about 15 degrees at the elbow Both wrists are loose in adduction, the left to a higher degree than the right, and just above the carpus the radius can be palpated on the inner as well as the outer aspect Fists can be clenched tightly with the appearance of one or two small double knuckles Wrists not greatly enlarged Patient says that she formerly had a large mass on the ribs on the right side, but this disappeared four years ago, after she began to wear corsets It is not to be felt now

Moderate degree of knock knee Large rough lumps to be felt above and below both knees There are lumps and irregularities on the lower ends of both tibiae and fibulae Slight degree of flatfoot, but on the whole the ankle mortise is well maintained

Roentgenologic Examination Cranium negative, normal sella turcica Thorax shows a slight caving in of the ribs, especially on the left, enlargement of the costochondral junctions (rosary), and a tear-drop exostosis on the lower border of the fifth left rib, one third of the way around from behind No scoliosis Some irregularity about sacro-iliac articulations Pelvis shows very wide ilia, and unusually thick pubes and ischia, with a relatively small superior strait Clavicles thick, with enlargement at outer ends Scapulae not remarkable Upper ends of humeri show irregular enlargement of diaphyseal extremities, with longitudinal striation About one third of the way down the shaft of the humerus on both arms is a moderate enlargement, from which project rounded stalactite exostoses Elbow joints appear normal The ulnae are relatively short In a plate taken at the age of 6 the lower ends of the ulnae are irregularly enlarged, but do not reach to within an inch of the carpal articulation The epiphysis cannot be distinguished The lower ends of the radii are somewhat enlarged and irregular, particularly the right, the epiphyses are clear cut, but small In the recent plates (taken at 18 years) the irregularities are much less the bones showing a denser structure, with a straighter outline There is no evidence of epiphyseal line The right ulna ends in a point, which articulates laterally with the radius, and on the left it resembles a spear head There is a fine retrodirected exostosis on the outer aspect of the lower end of both radii The metacarpals and phalanges in the 6 year plate show irregular enlargement and vacuolation of the diaphyseal ends most marked in the metacarpals There is a spur on the left forefinger, the right middle finger is disproportionately long and the distal phalanx subluxed inward The later plate shows the same conditions except that the bone is denser and the outlines less irregular, and the epiphyses have disappeared in moderate globular striated enlargements at the ends of the bones At the hips, the femoral necks are short, and very much increased in width, the outlines are irregular and the trochanters prominent The shafts are of normal contour down to the lower ends, which are squared striated longitudinally, and present hooklike exostoses, directed upward The same lengthening and squaring of the diaphyseal extremity is apparent in the upper end of the tibiae but here the pair of stalactite exostoses are directed downward The upper ends of the fibulae show marked irregular globular enlargement, cystic in appearance, much larger on the left There is moderate genu valgum The shafts of fibulae and tibiae are clear Their lower ends are broadened, and there is a long irregular pseudarthrosis between them The fibulae are relatively short, but the axis of motion of the ankle joint is not disturbed In none of the late plates is there evidence of an epiphysis

The deformities in this case consist in disproportionate shortness of stature, deformity of thorax, rosary, shortening and bowing of forearms, ulnar deviation of the hands, subluxation and asymmetry of fingers, moderate genu valgum, moderate pes valgus, enlargement of the diaphyseal extremities at shoulder, knee and ankle, a few exostoses, and a chondromatous enlargement of the upper end of the fibula The occurrence is symmetrical, although the degree varies slightly

The early plate was taken at the Children's Hospital, the later plates at the Boston City Hospital

CASE 3 —*History* —Mr F R J, aged 56, white, janitor, first seen May 11, 1915, in the orthopedic outpatient department of the Massachusetts General Hospital, by courtesy of Drs Brackett and Low, was born in Vermont, of American parents Father died in 1910 at 82, mother died in 1915 at 87 Family short in stature Father and mother both of same height as patient One sister died in infancy One brother living and well, of normal height Grandparents American born No history of deformities or exostoses

The patient had measles and pertussis as a child Denies venereal diseases, does not use alcohol At 7 or 8 years outgrowths and deformities were first noticed Taken to local physician who said that patient had exostoses and would probably be a cripple At 14 an extensive crop appeared growing "as fast as he grew," some being painful or tender at times Went under treatment with a "quack doctor for three years, he stopped the pain and stopped the bunches from increasing in size Since then he has had no new bunches, no increase in size, no disappearances

Had occasional growing pains or rheumatism when young, at 19 inflammatory rheumatism, in bed one week

Has always been able to do heavy work, when younger could run upstairs with a bag of corn over his back No trouble with walking No bunch is large enough to interfere with the free action of any joint

Physical Examination —The patient is a genial, intelligent-looking American Height 5 feet, 2 inches Middle point is 3 inches above pubes Finger tips reach to point short of midthigh

Upper arms not remarkable Lower arm short and curved No dislocation of radial head No club hand, although entire articulation is carried on radius Hand is stubby, no limitation in closure, but both fourth fingers are short, the same length as little fingers

Stands with considerable knok knee, greater on the right, approximating 45 degrees The right knee, probably in part as the result of the injury already noted, allows of lateral mobility of about 20 degrees Both knees very large, with palpable exostoses Lower legs fibulae short, with dislocation valgus, more marked on right No limitation of motion at knee or ankle Good function knees and ankles, except at right knee, as noted

Roentgenologic Examination I have plates only of the arms and legs The shoulders show the characteristic striated elongation of the upper end of the humerus The ulnae are short, curved, and articulate with the inner surface of the radius The lower ends of ulna and radius are irregularly enlarged, and of thinner texture than the shafts The knees show marked valgus, elongation and squaring of the diaphyseal ends, with irregular exostoses at the corners, projecting upward on the femur and downward on the tibia The upper ends of the fibula are enlarged and thinned, and run by direct fusion into the tibiae The lower ends of the tibia and fibula are distorted, on the right there is fusion of the two bones On the left there is a pseudarthrosis The fibulae are short, there is a fair ankle mortise, but the axis of motion of the astragalus is oblique, rather than horizontal

The deformities in this case are disproportionate shortness of stature, shortening and curvation of forearms, mild ulnar deviation of the hands, shortness and asymmetry of fingers, knock knee pes valgus, hyperostoses and exostoses about joints The deformities are symmetrical

The plates were taken at the Boston City Hospital [20]

Case 4—*History*—Mrs E H H, aged 20, white, first seen, May 25, 1915, at her home in Somerville, through the courtesy of Drs Binney and Kimpton was born in Montreal, Canada Father was an Englishman, from Sussex He was about 5 feet 8 inches in height, and is not known to have had any deformity He died in 1910 at 48 Mother was a French Canadian, born in Montreal, of normal height, and is not known to have had any deformity She died in 1915 at the Boston City Hospital The family consisted of eleven children three boys and eight girls, of whom the patient is the fifth One boy and one girl died in infancy The others are living and well, and are said to present no deformity This patient is the only one who is distinctly below normal height

Physical Examination—Patient is 5 feet 5½ inches in height Middle point is just above pubes The right arm is 25 inches and the left arm is 24¾ inches The outer ends of the clavicles are rough, and on the right there is a sharp knob The forearms are short, somewhat curved right, and sharp curve left Wrists enlarged, but no disability Can close fists Middle fingers long

Moderate knock knee, some pes valgus, but feet seem good from point of view of function Ankles enlarged Large knob on the outer side of femur above the left knee

Roentgenologic Examination Cranium negative, sella turcica normal in size Thorax shows a very pronounced caving in of the ribs on both sides There is an irregular enlargement of several of the ribs, particularly the first four on the left and the first two on the right There is a synostosis between the third and fourth, left The spine shows a double scoliosis The sacro-iliac joint and pelvis are clear The clavicles are thick and enlarged at both extremities The scapulae show small irregularities, upper end of humeri show small united epiphyses On the left the contour is normal, but there are several fine exostoses, and on the right the shaft near the upper end shows irregular cystic enlargement with small exostoses The lower halves of the shaft are free and the elbow joint is normal The forearms are short with a very marked relative shortening of the ulnae The radius is curved and its lower end irregularly enlarged There is no epiphyseal line apparent The articular surface of the radius stands at an obliquity of about 45 degrees to the shaft making a potential manus vara, with a very weak wrist The fingers show globular enlargement at the metacarpophalangeal articulations and the first interphalangeal articulations particularly The middle fingers of both hands are relatively long The upper ends of the femur are thick, with short thickened necks The shafts are free down to the lower diaphyseal extremities, which are square, elongated, striated longitudinally and present several exostoses directed upward The upper diaphyseal extremities of the tibia and fibula are similarly squared and elongated and present exostoses directed downward The lower diaphyseal extremities are elongated and present pseudarthroses The ulnae are relatively short, and the tarsi are in valgus

The deformities in this case are disproportionate shortness of stature scoliosis, deformity of thorax and ribs, shortness and curvation of the forearms, ulnar deviation of the hands knock knee pes valgus, asymmetry of fingers and hyperostoses and exostoses about joints The deformities are symmetrical There is no evidence of epiphyseal line, except at the upper ends of the humeri

The plates were taken at the Boston City Hospital

Case 9—*History*—E L, boy, aged 12 white, seen May 22, 1916, at my office, was born in Cambridge, Mass, of Anglo-American parents Father well at the age of 42, height 5 feet 6 inches printer, born in Rockland, Maine He has three brothers and one sister all below medium height except the oldest The oldest has one child His father died of paralysis in the fifties, and his mother is living and well, in the sixties No history of deformity

Mother living and well at the age of 48, born in Rockland, Maine, 5 feet 6 inches in height Her father was a sea captain, above medium height He wore a corset for some "spinal trouble," and died in 1885 of Bright's disease at 53 Her mother was a delicate woman who died at 52 in 1890 of gastric cancer She was above medium height Her one sister is living and well No history of deformity She was married at the age of 17 No miscarriages, has lost no children One other child beside patient, a girl of 15, living and well, without deformity

Roentgenologic Examination—I have plates of the arm and knees of this patient at the age of 8, and plates of the entire skeleton taken at the present age of 12 The thorax shows no abnormality, spine slight scoliosis Pelvis shows marked irregularity about the epiphyses as well as considerable thickening of bone Clavicles show marked thickening of the inner ends, particularly on the right The scapulae show small spurs and irregularities, particularly about the head and neck The humeri are somewhat thickened and dense at the upper ends, with wavy outline, and the epiphyses are partly united Elbows some irregularity in bony structure and in outline about condyle of humerus The epiphyses are distorted in the early plate and show signs of partial union in the more recent picture The ulna on the left is markedly shortened and somewhat curved It ends in a point, which does not take part in the carpal articulation This point is capped by a small triangular epiphysis The radius is curved and thickened at the lower end, and the epiphysis is distorted The right forearm presents a practically straight ulna with slight irregularity in outline at the lower end, and a small epiphysis not united The radius is slightly curved, both epiphyses show partial union The fingers show striation at the metaphyseal ends, with slight disproportionate lengthening of the right middle finger The hips present marked thickening of the neck with irregular contour in the region of the lesser trochanter and partial union of the epiphysis The knees show squaring of the metaphyseal ends with striation and spur formation at the corners a process which is carried further in the more recent plate, the striated portion extending further up on the shaft and the spurs being increased in size There is slight knock knee, and the more recent plates show a partial union of the epiphysis The upper ends of the fibulae are vacuolated and the lower ends are irregular and vacuolated, and in contact with an irregular surface on the outer side of the tibia The shafts of tibiae and fibulae are clean cut The fibulae are relatively short The feet show calcaneal spurs and striation and irregularity of outline at the metaphyseal extremities of metatarsals and to a less degree on the phalanges

The deformities in this case are as follows moderate valgus at the left elbow, shortening and curvation of the forearm greater on the left, ulnar deviation of the wrists, particularly the left small hands with asymmetry in length of fingers on the right, moderate genu valgum, moderate pes valgus, disproportionate shortness in stature, and juxta-epiphyseal hyperostoses and exostoses

The plates were made at the Children's Hospital

GENERAL OBSERVATIONS

I have found in the American literature fourteen articles on this disease and four recorded case reports, the earliest dated 1875 The inevitable deduction seems to be that the condition is a rare one in this country The cases formally reported in these records number twenty-nine, but if the cases mentioned in discussion are added, as well as the relatives stated as being affected, the total is brought up to seventy-one Some of these, however, were not residents of the United States

But in comparison with these figures I can say that in a period of about a year in Boston I have unearthed the series of twelve cases herewith presented, and a few months ago Ashhurst reported a series of thirteen cases from Philadelphia Accordingly, it is easy to believe that with more widespread knowledge of the condition, an interested search will bring to light many cases in other communities, and raise the disease out of the ranks of uninteresting rarities

---

[20] September 26 this patient employed as an elevator man in a Boston hotel suffered a severe crushing injury of his right leg above the ankle I performed an amputation from which he is recovering uneventfully The specimen is being studied at the pathologic laboratory of the Harvard Medical School

As to the sex occurrence, adding my cases to the seventy-one mentioned above, there are seventy-three in which the sex is given Of these fifty-five are male and eighteen female, just about in the proportion of 3 1 This agrees with the figures which I stated in my previous article

The question of nationality is interesting, but it is a complicated one to work out in this country, where so many racial stocks are involved Many authors make no statement whatsoever on this point Dr Percy's family of twenty-six patients were of Dutch birth or descent, five others are given as being of German birth or descent, and there were two of Irish, and one each of Italian, Austrian, English, and French-Canadian birth or race One had an English father and French-Canadian mother The Austrian was a Jewess, and is one of the very few reported The negress reported by Dr Ashhurst is the only one I have found in the literature, although the disease is known to affect others than Caucasians Of the remaining forty-five some are stated as being native-born of Anglo-American stock, and the rest were probably for the most part of the same origin I previously stated that the German cases predominated in the literature (60 per cent), next followed the French (27 per cent) and English (8 per cent) All other countries together showed only 5 per cent This American series is interesting for the predominance of Anglo-Americans, and the occurrence in a negress and a Jewess

Heredity has been a hard matter to study in connection with the disease, because the country is young and the population mixed and to a large degree migratory Many of the case reports have been casual, and make no mention of this subject It happens that we now have several families authoritatively worked out in this country The largest is that of Percy, with twenty-six affected in four generations, then comes Gibney's with four in two generations, mine with three in two generations, Boggs with father and son, and Ashhurst with two, and probably three, brothers In addition there have been reported in discussion a girl with two brothers and probable father (Taylor), a brother and sister, with mother, grandmother, and great-grandmother (Ashley), and three generations (Freiburg) Accepting these, we may say that inheritance or familial occurrence was shown in fifty cases In the remaining thirty-two, it is stated in twelve that no evidence of heredity was obtained

The characteristics of the disease in the cases here reported have agreed well with my previous description of the disease The affection is distinctly one of the period of skeletal growth It has been usually first noticed in infancy or early childhood, the manifestations have increased with skeletal growth, and ceased at skeletal maturity Chondromatous tumors may increase rapidly in size, and regress, either before or after maturity, but the bony spurs, usually capped with cartilage, grow slowly and are undoubtedly fixed at skeletal maturity They may fracture, and the fractured portion absorb, or the bursa which frequently covers them may become inflamed from irritation, and form an abscess or subside, or a spur may become infected and carious It is unlikely that the bony elements regress in adults, although Davis records a case in which this apparently occurred under his observation in a man of 53

Disproportionate shortness of stature was constant in the seven of my cases in which it was measured for, and Ashhurst reports it as a finding in one case I believe that it will be found practically constant in well marked examples of the disease Generally, the cases have shown irregular juxta-epiphyseal hyperostoses, particularly marked at knee, hip, shoulder, ankle and wrist The lower end of the femur and the upper end of the tibia have shown a characteristic squaring-off, with spurs at the corners, running upward from the femur, and downward from the tibia These spurs should not be confused with the developmental exostoses about the knee, which are similar, but are purely local, and bear no definite relationship to this disease These spurs may increase in size and change their shape in the period of growth The enlargements at the metaphyseal ends increase in length with skeletal growth, in the younger patients they are thin in density, and striated or mottled in appearance, the older cases are striated longitudinally, and are dense in structure, with heavy more or less wavy outline

The lower end of the ulna, occasionally of the radius, and both ends of the fibula characteristically show a thin bubble-like vacuolation, suggesting cysts The bone becomes denser and the outline more regular in the older patients In the majority of cases the ulna and fibula are disproportionately short in relation to the radius or tibia The ulna is likely to end in a point articulating with the radius on its mesial aspect, but not partaking in the carpal articulation This gives rise to a club hand, or a weak wrist with ulnar deviation (potential manu vara) The relatively excessive length of the radius is also taken up in a bowing of the shaft, sometimes with a dislocation upward of its head, and rarely in a spiral twist about the ulna (case of Carman and Fisher) The relative shortening of the fibula disturbs the mortise at the ankle joint, and causes a structural valgus The tibia is a strong bone, with its ends firmly set into joints, and it does not become distorted from the shortness of its companion, as does the radius The fibula frequently becomes structurally united with the tibia at one or both extremities, sometimes, instead, there is a long irregular pseudarthrosis, particularly at the lower end

The fingers and toes show the same type of bulbous juxta-epiphyseal enlargement, vacuolated in the younger patients, becoming denser and more regular in outline later In marked cases these form double knuckles, and prevent complete closure of the fist Frequently fingers or toes are irregular as to length, one being longer or shorter than it should proportionately be There seems to be demonstrable correspondence between the amount of bony involvement and the extent of retardation in growth Generally, the hands are small and chubby Fingers may be crooked or a phalanx subluxed, from an irregular growth

The cranium is generally not involved, although in one case a spur on the left superior curved line of the occiput is cited (Ochsner and Rothstein) There may be growths on the jaw, or the mastoids and other prominences may be roughened and enlarged One case in this series was diagnosed as exostosis in the sella turcica, and Virchow found at necropsy that the occu rence of small spurs on the basilar process at the spheno-occipital junction was common The spine frequently shows a lateral curve, and occasionally spurs on the bodies or spinous process are demonstrable by roentgenoscopy Clavicles and scapulae frequently show spurs, thickening, or irregularities in outline, which, if subcutaneous, may cause ulceration of the skin The ribs often show enlargement at the costochondral junction (rosary), occasionally a spur, or a broadening of and synostosis between ribs There may be irregularities about the head and neck of the ribs, and occasionally the thorax shows a marked caving in of both sides

Growths at the lumbosacral junction and about the sacro-iliac joint are frequently demonstrable The pelvic bones are likely to be thickened, lessening the diameter of the superior strait, the crest may show striation, or there may be spurs on or within the crest The upper end of the femur is enlarged and irregular, and the neck is short and thick This may rarely interfere with function Knock knee in mild degree is common, and in excessive degree not unusual

Pediculated osteochondroma may arise from any affected portion of the skeleton, particularly from the juxta-epiphyseal hyperostoses They may grow rapidly in size, even after the cessation of skeletal growth The shafts of the long bones are likely to be free from irregularities or spurs, these grouping themselves at the metaphyseal ends It may be said categorically that the bony irregularities mark the progress of a disturbed or pathologic ossification at the epiphyseal line The epiphyses of the bones most affected usually show some distortion in the roentgenogram, and at the wrist this may be very marked The union of the epiphysis with the shaft occurs abnormally early, as a rule

The skeletal disturbances and malformations are generally speaking symmetrical for the two sides of the body Usually minor differences may be apparent, in degree of distortion, but it is rare to have any one side suffer a great deal and the other be only slightly affected This occurred, however, in one case, that described by Coon This patient resembles those of the small series discussed by Ollier, Wittek and Frangenheim, and in several other ways he departs from the rule I consider this case, however, to come within my definition of the disease

This series has brought out several cases representing the rarer complications of the affection Freiburg, in the discussion of Davis' paper, reported a case of popliteal aneurysm caused by friction of a bony spur against the artery There are only seven other cases of this sort on record

Nerve complications have been unusually frequent These include a case with syringomyelia and acromegalic symptoms, probably from a spur in the sella turcica (Oberndorf), cord symptoms from a pediculated intraspinal osteoma (Ochsner and Rothstein) and from a growth at the lumbosacral junction (Harris), both operated on, and peripheral manifestations, (1) in the ulnar nerve from pressure by a bony mass in the neck, and (2) in the sciatic from pressure of an exostosis (Ashhurst) The case of Boggs' had degeneration of the acoustic and optic nerves, muscular dystrophy and thyroid atrophy

There have been in this series no cases of secondary malignant chondroma In my previous paper I stated that this occurred in about 5 per cent of the reported cases

CONCLUSIONS

Hereditary deforming chondrodysplasia can no longer be considered a rare affection in this country The disease is a distinct clinical entity, whose manifestations are now well defined The work which has been done on its pathology points definitely to a disturbance in the bone-forming cartilage as the underlying cause The hereditary nature of the disorder, which has been pretty well demonstrated, gives it an individuality which makes investigation interesting The disease should be given wider recognition and study, not only for its importance, but also because it opens up the whole field of obscure congenital skeletal affections

ABSTRACT OF DISCUSSION

Dr Albert H Freiberg Cincinnati No one can discuss this subject to any great extent because so little is known of the true nature of this condition I can simply tell you the circumstances under which I saw a case very early in my surgical career, when, as assistant to a general surgeon, we operated on a popliteal aneurysm which was produced by fracture of the pedicle of one of these exostoses in the popliteal space The case was similar in all respects to the cases Dr Ehrenfried has shown us, and there was a very distinct history of transmission through the male side of the family for a number of generations

Dr Albert Ehrenfried, Boston This disease is not a rarity I have found seventy-one cases recorded in this country most of them in the past few years Ashhurst has just reported thirteen cases from Philadelphia, and the twelve in my series were collected in Boston in less than eighteen months so it cannot be very uncommon The disease is a distinct clinical entity Exostoses play a very small role, they were considered characteristic in the days when we had to depend on palpation for diagnosis, but now the Roentgen ray shows the whole bony picture The pathology of the affection has been cleared up to a considerable degree My own work has demonstrated a dysplasia of the intermediary cartilage as a basic element in the disease and the chief source of the skeletal deformities, and has corroborated the persistence of islands of cartilage as the probable source of the hyperostoses and osteochondromas The matter of heredity I have just touched on It is a fascinating subject, and when thoroughly worked out will undoubtedly assist us to a proper understanding of the whole group of congenital skeletal affections of which we now know so little

---

Artificial Milk —Vice Consul Hamilton C Claiborne, at Bradford, England (*Commerce Reports,* Jan 11, 1917) reports that application has been made for a patent on the process of making an artificial milk from peanuts, soya beans, sugar, water and mineral salts, which is said to be wholesome and inexpensive The method of making the milk, as taken from the Yorkshire *Observer,* is as follows In 200 pints of pure water at 80 C are dissolved 400 grams of potassium phosphate, or the equivalent amount of sodium phosphate, sufficient sugar is added to give 4 5 per cent to the finished milk, and 40 pounds of meal prepared from one of the above nuts, blanched The solution is boiled in a steam-jacketed pan, then subjected to the operation of a vacuum pan and finally treated with a culture of lactic bacteria until the required acidity is obtained It is afterward pasteurized at 60 and 70 C for at least twenty minutes cooled and stirred while 0 05 to 0 11 per cent of citric acid is added The milk so produced is said to be condensed and sold in tins or dried to a powder and sold in bottles It may be given a certain percentage of cream, it is said, by the addition of coconut or one of the other tasteless nut fats, the fat being added when in the vacuum pan It may be cultured by the addition of lactic bacteria to give a table cream or a soured mass for making into cheese

COMPRESSION PARALYSIS OF POTT'S DISEASE IN ADULTS*

CHARLES M. JACOBS, M.D.
Associate Professor of Clinical Orthopedic Surgery, University of Illinois College of Medicine; Attending Orthopedic Surgeon Cook County Hospital and Home for Crippled Children
CHICAGO

In reviewing my own experience relative to compression paralysis of Pott's disease in adults, I have been impressed by the frequency of its occurrence, of the severity of the symptoms, and the mortality. The general picture of Pott's paraplegia in adults, compared with that usually seen in children, justifies a discussion of the problem which is distinctive in many regards. To approach this subject it is necessary to quote data not only obtained from the records of my own service, but also from other services at Cook County Hospital.

In seventy-five cases of adult Pott's disease, examined and treated at this hospital from January, 1914, to May, 1916, between the ages of 19 and 62 years, paraplegia occurred in twenty-four cases, and of these the known number of deaths was sixteen. The termination in the remaining eight cases is unknown. Surgical procedure, such as osteoplasty or laminectomy, was performed in thirteen of the twenty-four cases at some period in the course of Pott's disease. Postmortems were held in seven cases, of which five had compression paralysis.

Unfortunately a full analysis of my series of cases of Pott's disease is impossible on account of the incomplete records of the cases; nevertheless, they warrant a definite opinion that pressure paralysis of the cord is relatively frequent in adults. That this complication of Pott's disease should be of frequent occurrence ought not to be surprising, considering the immediate proximity of the cord to the site of the disease.

There are two factors to be considered in compression of the spinal cord in tuberculous spine disease: first, pressure from tuberculous granulation tissue which occurs mostly in children, and second, pressure from intraspinal abscess, usually seen in adults. Though other factors have been prominently mentioned, such as alteration in the position of the vertebrae, producing an angled projection of the spinous process, and protruding sequestrums at the site of the kyphos as a sequence of vertebral destruction, they should not be seriously considered. As to the angled projection, the caliber of the spinal cord is not narrowed in the anterior-posterior direction, as is generally supposed, and sequestrums are improbable.

In adults, compression of the spinal cord and nerve roots is most frequently the result of intraspinal abscess, although occasionally due entirely to granulation tissue. It is not exceeding the limit of probability to state not only that intraspinal abscess leads to paralysis, but also that the pressure will usually be protracted and tend to produce severe injury to the cord. Eventually the abscess may make its way out of the spinal canal into the deep tissues, though without corresponding relief of the symptoms. In exceptional cases, however, the paralytic symptoms may disappear if the pressure has existed only for a short time and has been relieved by the migration of the abscess outside of the vertebral canal.

Intraspinal abscesses are interpreted in roentgenograms as irregular, dark, wavy shadows surrounding apparently destroyed vertebrae. On the roentgenograms of patients with tuberculous spines, available for examination, intraspinal abscesses were observed in eighteen. Of this number fifteen had clinical symptoms of compression paralysis; whether or not the other three cases developed paralysis is unknown. In two paralytic patients with no characteristic symptoms of tuberculous spine disease and in which the roentgenograms did not show either vertebral bone destruction or shadows indicating abscess formation, the diagnosis of Pott's disease with intraspinal abscess was made only after postmortem examination. Five paraplegic patients went to postmortem, and intraspinal abscesses were found in all.

In children the majority of cases of Pott's paraplegia are due to pressure from inflammatory changes in the dura mater, the result of extension of the tuberculous process into the vertebral canal. This produces a disturbance of function without setting up a destructive or degenerative process. Only occasionally does an intraspinal abscess occur. These observations are based on (1) the examination of roentgenograms of tuberculous spines in children, which seldom show shadows indicating intraspinal abscesses, and (2) the fact that children afflicted with Pott's paraplegia when treated by recumbency on a Bradford frame, with or without traction, generally recover.

That recumbency can influence ultimate recovery in Pott's paraplegia where there has been severe and protracted pressure with consequent injury to the cord is improbable. In my opinion, restoration of function following recumbency ensues only when the stress has been moderate, as from tuberculous granulation tissue. Therefore, when recovery follows compression paralysis of Pott's disease, either in children or in adults, the lesion must generally be considered as having been a tuberculous granulation tissue rather than an intraspinal abscess. Of the twenty-four patients afflicted with Pott's paraplegia, due to intraspinal abscess, not one complete recovery has been recorded; generally death has resulted; but in those cases which, perchance, have not proved fatal, the degenerative changes in the cord were so great that a permanent paralysis remains. However, one patient (Case 3) partially recovered.

The treatment of so persistent an affection as Pott's paraplegia, the result of intraspinal abscess, has been without favorable effect. In the routine treatment of Pott's disease, I have operated both by the method of Albee and Hibbs, but neither has made any noticeable impression on the paralysis. Laminectomy, too, has been tried without securing results. In fact, where laminectomy was performed on four patients, death followed within a short period.

Postmortem examination in the five patients previously mentioned revealed total destruction of one or more vertebrae with abscess formation. The abscess communicated through the space formerly occupied by the destroyed bodies of the vertebrae, compressing the spinal cord. The dura mater was enormously thickened, markedly infiltrated and covered by yellowish, caseous material and occasionally by soft granulation tissue masses; the inner surface was smooth. The spinal cord was hyperemic in the region of the compression, and was completely severed in three cases.

---

* Read before the Section on Orthopedic Surgery at the Sixty-Seventh Annual Session of the American Medical Association, Detroit, June, 1916.

In one case it was compressed from side to side Pulmonary tuberculosis was the primary cause of death in four cases

The following cases are selected to substantiate my observations of compression paralysis of Pott's disease, and also to introduce phases of the subject not hitherto discussed in the text of this paper

REPORT OF CASES

Case 1—W C, man, aged 56 years, admitted to the medical service of Cook County Hospital, June 24, 1914, complained chiefly of pain in the left side of the chest for the past two weeks, and during this time cough developed which gradually grew worse

The lungs gave a distinct friction rub in the left side, and a few rales could be heard Tubercle bacilli were found in great numbers, reflexes were normal

Aug 7, 1914, the patient complained of a beginning weakness in the legs Three weeks later he could not walk without support At this time he had a steppage gait, exaggerated knee jerks and ankle clonus on the left side No deformity of the spine nor typical symptoms of Pott's disease were present Roentgenograms showed destructive lesion of the third, fourth and fifth dorsal vertebrae and a shadow denoting abscess formation

Sept 14, 1914, he complained of pain in both legs The knee jerks were markedly exaggerated, Babinski was present and there was incontinence of urine, etc He was transferred to the orthopedic department, and from there referred back to the ward for pulmonary tuberculosis, because he was not considered an orthopedic case

He died, Oct 11, 1914, and a necropsy showed caseous tuberculosis of the tracheobronchial lymph nodes, apical pulmonary tuberculosis, necrosis of the fifth and sixth dorsal vertebrae and a tuberculous abscess communicating through these vertebrae, pressing on the dura mater Microscopic examination of the spinal cord was not made

Case 2—H H, man, aged 22, entered the neurologic department of Cook County Hospital, Jan 18, 1915 complaining of pain, numbness, heaviness and stiffness in both lower extremities, and also difficulty in walking Seven years previous he had tuberculosis of the cervical region of the spine, but he has been without any discomfort up to one year ago, when the foregoing symptoms appeared

Muscle power is good in the upper extremities, but decreased in the lower, both lower extremities are spastic, the right more than the left, tendon reflexes markedly exaggerated, Babinski is present and ankle clonus increased There is a small kyphos in the region of the eleventh dorsal vertebra

Roentgenograms show bone destruction of the lower dorsal and first lumbar vertebrae, but no apparent shadow indicating abscess formation

The diagnosis is compression myelitis of Pott's disease

Feb 20, 1916 laminectomy was performed and the patient died about two weeks later No postmortem was held

Case 3—M S man, aged 20, admitted to my service at Cook County Hospital, May 31, 1915, as a transfer from the tuberculosis ward, stated that he had been coughing more or less for about one year Six months ago he became aware of a small deformity in the dorsal region of the spine which had increased in size He suffered no particular discomfort other than the inability to bend the spine freely In the past four months he noticed a gradual difficulty in walking—a sense of heaviness and stiffness in the legs

The gait is slow, with a stiffness and dragging of the feet, tendon reflexes are exaggerated, there is loss of muscular power, and loss of cremasteric and abdominal reflexes, Babinski is present and ankle clonus increased There is a small kyphos at about the seventh to the ninth dorsal vertebrae, and impaired resonance of the left upper lobe and the right lower lobe, together with a few subcrepitant rales

Roentgenograms show collapsed bodies of the eighth and ninth dorsal vertebrae and a very classical shadow around the seventh to the tenth dorsal vertebrae indicating cold abscess

The diagnosis is tuberculous spine with beginning paraplegia and incipient pulmonary tuberculosis

June 15, 1915, the Albee operation was performed

Dec 1, 1916, the condition on discharge to Oak Forest Infirmary was about the same as mentioned above

June 6, 1916, the patient returned to Cook County Hospital for examination He walked with a quick, firm step, the tendon reflexes were markedly exaggerated, Babinski was present and ankle clonus increased

Roentgenograms showed a shadow surrounding the seventh to the tenth dorsal vertebrae indicating a cold abscess

Case 4—M M, woman, aged 31 years, admitted to Cook County Hospital, April 23, 1915, complained of parasthesia in legs and feet, she was unable to use the lower extremities, and also there was incontinence of urine and feces The paraplegia began eight months before with sensation of tingling, numbness and a "dead feeling" which steadily increased Previous to this time she had been well

There was complete paralysis in the lower limbs, spastic in type All reflexes were exaggerated and Babinski positive on both sides Sensory disturbances were limited to the lower half of the body up to the region of the umbilicus, running in a circular line around the body, there was kyphos in the region of the third and fourth vertebrae Bladder and rectal disturbances were marked There were trophic sacral bedsores

Roentgenograms showed marked bone degeneration involving the fourth to the twelfth dorsal vertebrae and also a very definite shadow opposite the fourth to the eighth dorsal vertebrae, indicating cold abscess

The diagnosis was tuberculous spine disease with paraplegia

Patient died, May 22, 1915, and necropsy revealed a cold abscess the size of the fist in the region of the third to the fifth dorsal vertebrae projecting anteriorly into the chest cavity The sac of the abscess was thick and on opening a cheesy, yellow tuberculous pus exuded The bodies of the third, fourth, fifth and sixth vertebrae were destroyed, through which the abscess sac compressed the spinal cord to the extent of almost complete severance The dura mater was markedly infiltrated—a peripachymeningitis—in the region opposite the lower part of the cord and cauda equina The spinal cord was curved on itself in the upper dorsal region Microscopically the gray matter was broken up in separate patches irregularly scattered over the surface, so-called heterotopic changes which are considered to be artificial Above and below the focus of softening there were found ascending and descending degeneration In the posterior and lateral columns were circumscribed foci of softening surrounded by some glia tissue

Case 5—E K, man aged 22, entered the neurologic service of Cook County Hospital June 15, 1915, with the following history About two weeks previous he became aware of a difficulty in getting out of bed, for the next three or four days he could manage to get up and around to a slight extent, but if he tried to move fast he would fall At the present time he is unable to walk and has slight pains in the shoulder and back Otherwise the history is negative

In the left supraclavicular space and just in front of the right trapezius muscle, apparently connected with it, is a soft, painless, freely movable tumor about the size of a small hen's egg, patient states that this tumor appeared about five days previous to his inability to walk On the left pectoralis major muscle, near its origin, is a soft, distinct painless tumor extending from the second to the fifth rib the size of a man's palm, which has been present for about two months No fluctuation is obtainable Below this tumor is a small, painless, fluctuating one about 1½ inches in diameter from which a brownish, yellowish fluid was aspirated The tendon reflexes and exaggerated Babinski, Gordon and Oppenheim are present Anesthesia is complete in the lower limbs up to the level of the eleventh dorsal vertebra, from the seventh to the eleventh dorsal vertebrae there is hypesthesia, pain, heat and cold touch are lost in this region, there is apparent lack of control of the sphincter muscles There is deformity of the spine

The luetin test proved negative The Wassermann blood test was positive, while the Wassermann spinal fluid test, made ten days later, proved negative Roentgenograms showed no destructive changes in the vertebrae nor a shadow indicating abscess formation

The diagnosis of myelitis (traumatic or compression) was made

The patient finally died, Dec 3, 1915 Necropsy showed miliary tuberculosis of both lungs, fibrocaseous tuberculosis of the tracheobronchial lymph glands, and fatty degeneration and passive hyperemia of the liver A tuberculous abscess, about 4 cm in diameter, was bulging from the fifth and sixth dorsal vertebrae, the bodies of which were completely destroyed On opening the vertebral canal there was a tuberculous, cheesy mass surrounding the dura mater opposite the fifth and sixth dorsal vertebrae The dura mater over the dorsal and lumbar region was found enormously thickened and covered with caseous and soft granulation tissue masses On opening the dura mater, the inner surface was smooth, but hyperemic, the cord too was hyperemic Microscopically the lower cervical region of the cord showed a patch of softening occupying the posterior horns and part of the posterior columns The axons were found swollen and broken up in small fragments, while the hyalin was in the form of lumps, drops or droplets The glia showed the so-called ameboid transformation In addition there were present the usual findings of ascending and descending degeneration

CASE 6—M O, woman, aged 25 years, entered my service at Cook County Hospital, July 3, 1915, as a transfer from the neurologic service Six months before she complained of pain in the abdomen followed by numbness and tingling in both legs One month later she lost complete power in the lower limbs About two months afterward an operation (laminectomy) was performed

Both legs lie extended and immobile, patellar reflexes, ankle clonus and Babinski are absent There is a scar over the region of the middle and dorsal vertebrae as from recent operation There is no apparent kyphos Sitting up increases the pain referred to the abdomen There is incontinence of urine, there are trophic ulcers over the sacrum and some dry rales over the right chest anteriorly

Roentgenograms show destruction of the tenth and eleventh dorsal vertebrae, and also a very definite shadow in the region of the seventh to the eleventh dorsal vertebrae indicating cold abscess

The Wassermann test was negative

The diagnosis was tuberculosis of the spine with paraplegia and pulmonary tuberculosis

Necropsy revealed a cold abscess about the size of a lemon along the ventral aspect of the dorsal vertebrae and communicating through the space formerly occupied by the bodies of the tenth, eleventh and twelfth vertebrae, which were completely destroyed The anterior and lateral portion of the seventh and eighth dorsal vertebrae were roughened The dura mater was thickened and covered by cheesy material, the inner surface was smooth The spinal cord was seen to be entirely severed at this level There were fibrocaseous ulcerative tuberculosis of the lungs, fatty degeneration of the liver and kidneys, trophic ulcers, etc

CASE 7—M T, woman, aged 25, entered my service at the Cook County Hospital, July 26, 1915, with a history of tuberculous spine disease of two years' duration for which she had been treated About three weeks previous to her entrance to the hospital her legs became weak and finally she was unable to move them She also suffered from incontinence of urine

There are typical symptoms of compression myelitis, and a kyphos in the upper as well as in the lower dorsal region of the spine Roentgenograms show apparent necrosis of the bodies of the fourth, fifth, sixth, seventh and twelfth dorsal and first lumbar vertebrae, and also a shadow in the region of the middle to the lower dorsal vertebrae, denoting abscess formation

The diagnosis is tuberculous spine disease with paraplegia

Dec 15 1915, necropsy revealed a focus of encapsulated, fibrous, caseous tuberculosis in the apex of the right upper lobe of the lung, bilateral fibrous adhesive pleuritis, marked bilateral disseminated bronchopneumonia, between the third and fourth dorsal vertebrae, there was a possible partial dislocation of the spine, that is, there was a necrosis of the bodies of the second, third and fourth dorsal vertebrae, and between the third and fourth, this necrosis was so marked that the normal intervertebral attachments were loosened to permit of marked abnormal mobility The bodies of these bones were, so to speak, collapsed on each other In opening the iliopsoas group of muscles on either side, there was a large quantity of yellowish, cottage cheese-like material which had excavated a cavity in these muscles approximately 4 by 18 cm There were sinuses leading from the upper end of these cold abscess cavities to the region of the twelfth dorsal and the first lumbar vertebrae The bodies of the seventh, eighth, ninth, tenth, eleventh and twelfth and the first lumbar were necrosed, of softened consistency, and yellow Between the twelfth dorsal and the first lumbar there was so much necrosis that here, too, the bodies had collapsed to make the angular deformity described in the lumbodorsal region On removal of the spinal cord there was a marked narrowing of the spinal canal in the upper dorsal region adjacent to the third and fourth dorsal vertebrae This narrowing was so marked as to have caused a definite marked narrowing of the adjacent spinal cord The dura mater in this region was greatly thickened, and on its exterior surface had a granular appearance and yellow color as that found in the adjacent bone In the lumbodorsal region, there was no narrowing in the spinal canal The dura mater at this point, however, was greatly thickened, and there was some dependent edema of the leptomeninges There were no adhesions between the leptomeninges and the dura mater in any part of the cord The lumbodorsal bone necrosis was at the level of and below the beginning of the cauda Between the dura and the bodies of the lower dorsal vertebrae, there was an infiltration of cheesy material This infiltration is an extension from the necrosed dorsal and first lumbar vertebrae The deformity in the upper dorsal region has been produced by a slight collapse of the bodies of the third and fourth vertebrae, the deformity not being great, the collapse is not great The necrosis of the arches of these vertebrae is so great that the narrowing of the spinal canal is in the lateral rather than in the anteroposterior diameter This encroachment on the lumen of the spinal canal is due to an infiltration of the dura with caseous material and the consequent fibrous infiltration of that membrane

Microscopically the spinal cord gave the typical picture of so called diffused myelitis, that is, the cord had the Swiss cheese appearance, numerous vacuoles, swollen axons broken up myelin and the so-called ameboid transformation of glia The vessels showed marked infiltration of the adventitial lymphatic spaces In addition there were present signs of secondary degeneration

SUMMARY

Compression myelitis may be the first clinical sign of an unsuspected Pott's disease, often unmasked by roentgenograms The severity of the compression is correspondingly shown by the intensity of the clinical phenomena

Intraspinal abscess is the dominant factor in subjecting the spinal cord to pressure, borne out by laboratory examinations and postmortem findings At first the pressure may not make any appreciable alteration in the nerve element, but sooner or later there is severe damage to the cord resulting in primary and secondary degeneration, in time actual necrosis and severing of the cord may occur as already recorded It therefore follows that the paraplegia will be complete and permanent, though occasionally it may be but partial As a rule, death may be anticipated—generally from pulmonary tuberculosis It cannot be denied, however that complete recovery may take place even after the paralysis has existed for a long period of time But in this connection a second factor must be considered in the mechanism of compression, namely, tuberculous granulation tissue most commonly occurring in children, which invades the vertebral canal, and a moderate pressure is manifestly enough to excite functional disturbance without necessarily having an actual mechanical destruction of the nervous elements This fact is of practical importance, as it explains the cause of recovery, which occurs by absorption of the tuberculous granulation tissue

No reliance can be placed on operative procedure Where laminectomy has afforded relief, it has been due to the accidental evacuation of the abscess, it is a serious operation and the immediate mortality is large

ABSTRACT OF DISCUSSION

Dr C B Francisco, Kansas City, Mo Formerly we were taught that Pott's paraplegia was, as a rule, the result of bony pressure It is now generally considered that the pressure is due either to granulation tissue, abscess formation or an extension of the process to the meninges In children I believe that the pressure is usually the result of granulation tissue, and that recovery is the rule Occasionally a child will not recover completely Recently I had a necropsy on a child who had had very efficient treatment for ten years, it had started off with the paralysis early in the disease, and had been continuously paralyzed, walking, at times, with considerable difficulty In that case we found a direct extension to the meninges (that is, an infiltration due to extension of the process), but these cases, I believe, are very rare There is seldom bony pressure in children, if ever In adults, it has been my observation that a case of tuberculosis of the spine developing paraplegia is going to continue to have signs and symptoms of the paraplegia Whether the original pressure is due to abscess formation or meningeal involvement, it is maintained sufficiently long to produce destruction of the cord structures and removal of the pressure then does no good therefore it is useless to do a laminectomy These cases will continue to have exaggerated reflexes and considerable difficulty It is rather rare, I believe, to see a case that improves as much as the one Dr Jacobs reports, in which the patient became able to walk very well, but still had the reflexes exaggerated

Dr J T Rugh, Philadelphia My experience rather leads me to feel that the prognosis in adults depends very much on the involvements or complications in other parts of the body If the patient does not have any pulmonary lesion or any active lesion in other parts of the body, the prognosis of the spinal condition is better A year or so ago, I had a case of paralysis of about a year's standing, in the Philadelphia General Hospital As a last resort, and because of inability to control the patient as he was, I placed a bone-graft in the spine Six months later, he met me in the corridor walking around with a cane It is now two years since the graft was inserted and he is now driving a dray in the city I have been able to duplicate that result in several other patients with disease of a similar type, in which there was no complication Those of my patients who have not recovered or have shown no improvement have usually died of complications, pulmonary, renal, or whatever they might be

Dr A L Fisher, San Francisco There ought to be a complete neurologic examination in all these cases as a routine For the last year we have been making not only the examination of the motor nerves and reflexes, but also of sensibility tactile sensation, cold and heat sensations, etc Although the results are not yet sufficient to draw any conclusions I have seen some evidence that there are in some instances disturbances of sensation before any evidence of motor impairment is shown

Dr Reginald H Sayre New York I agree with Dr Rugh that it is the lesion in some other part of the body that generally proves fatal in these cases, and my personal experience has been that a much larger number recover with good function than would seem to be the history with the patients whom most of the other gentlemen have seen I have under treatment at present three adults who were paralyzed for periods of from six to eighteen months They had both sphincters paralyzed, and in two cases there were bedsores These patients have practically recovered Two of them are supporting themselves The other patient has so far recovered as to be able to move around the ward with difficulty, but she has improved so much within the last six months that I think she will make a good recovery ultimately She was a mass of bedsores when she first came under my observation, and a diagnosis of transverse myelitis had been made, Pott's disease not being suspected Nothing had been done, but with traction and hyperextension in bed, she began to recover very soon She has slowly increased in her capability of looking after herself, and is, I believe, on the way to recovery In most of the fatal cases that I have seen, the pressure was in the cervical region I have seen several that went to a fatal termination, and there was marked meningitis at the time of death—the cerebral meninges being involved as well as those of the cord

Dr F J Gaenslen Milwaukee, Wis I want to report a procedure that I used in two instances in which the paralysis came on suddenly, and in which the condition would probably have terminated fatally otherwise The first thing I did was a laminectomy, splitting the spines as you would in an Albee operation The advantages of that are that when you close up the wound, you have a very firm line of union In addition to the laminectomy, I put in a tibial graft over the laminectomized portion of the spine In one instance, I removed the laminae of the fourth, fifth and sixth cervical, and in the other three laminae in the dorsolumbar region

Dr James T Watkins, San Francisco I want to report progress in a case belonging to the group described by Dr Jacobs The patient was a young woman with a complete paraplegia and multiple sinuses pointing in her back low down In the hope of inducing these abscesses to discharge elsewhere and so enable me to get a clean back to operate on, I had her put on an inclined plane My hopes were realized In time she developed sinuses in each groin and those in the back healed up Shortly afterward I went off service and Dr Sherman took the case over He did a laminectomy and removed a large tuberculoma from the neural canal The outcome to date is most gratifying It is less than six months since the operation and she already walks with assurance

Dr Edward S Hatch, New Orleans I agree with Dr Rugh that if they do not have other complications these adult patients do well I see many adult negroes come to the Charity Hospital with paraplegia or great weakness, and in the cases in which there are no other complications, the prognosis is good I have one man who was absolutely paralyzed, but who could get around a little in three months and is steadily improving It is a great mistake to say that we cannot do anything for these patients

Dr Albert H Freiberg, Cincinnati There is very little difference of opinion as to the correctness of the general considerations which Dr Jacobs has placed before us At the same time, I question whether we may applaud all that he has said with reference to these cases, whether in child or in adult The demonstration of an abscess around the spinal column in a roentgenogram in a case of paraplegia does not prove that the abscess stands in direct relation to the paraplegia Neither is it possible to be quite so definite as to what is going to happen as the result of conservative treatment in child or adult The proof cannot be seen in the roentgenogram, but in the conduct of the case What is important is that we should first use adequate mechanical means for placing the spine in a properly corrected position and for maintaining an exact immobilization with comfort to the patient and for a sufficient length of time to be able to judge, by the patient's behavior afterward, whether he is improving or not If he is not, we are not accomplishing what we are after, and then the question of some other kind of intervention comes up This is as true with reference to the child as to the adult, but the difference between the two classes of cases lies in the fact that improvement is more likely and more rapid in the child than in the adult For these cases it is my custom to use the Lorenz plaster bed and not the Bradford frame for immobilization By this means I can secure what we call hyperextension, but which it would be better to describe as a corrected position, and, in addition, I hope, a greater degree of immobilization This appliance is always under control and enables one to see that the patient receives proper care of the skin Our experience has been most gratifying in the treatment of these cases I may have been more fortunate than most We are going through this experience with some cases now The ultimate fact to be looked for is continuous improvement, even though slow So long as that is going on, I feel that we are moving in the right direction

Dr C M Jacobs, Chicago I do not deny that some patients get well, but what I have tried to bring out is that when this occurs the pathologic lesion is a tuberculous granulation tissue rather than an intraspinal abscess We know that most children with Pott's paraplegia get well, on the other hand, my records show that out of twenty-four adult cases, sixteen were known to end fatally Children with Pott s paraplegia are placed on a Bradford frame, with or without traction, and as already stated they usually get well The roentgenograms in these cases do not show a shadow indicating abscess When the roentgenograms show abscess formation there is more or less permanent paralysis At the Home for Crippled Children, I have two patients with Pott's disease who have been paralyzed for the past two years I have tried in every way to modify the condition by different methods—particularly with rest, but without success The roentgenograms show a shadow which I have diagnosed as an intraspinal abscess According to my observation, Pott's paraplegia in adults, due to intraspinal abscess, is usually followed by complications such as pulmonary tuberculosis, bronchopneumonia or tuberculous meningitis Dr Sayre did not state whether roentgenograms were taken of his cases and if so whether a shadow was shown indicating abscess formation

Dr Sayre In both of my cases I believe that there was an abscess present, because, after the disappearance of the paraplegia, abscesses showed themselves—in one case, in the spine, and in the other, in the groin These abscesses were opened and washed out, and disappeared

Dr Hibbs These were intraspinal abscesses, not ordinary abscesses?

Dr Sayre I believe that these abscesses had their origin in the spinal canal as the result of a process going on in the vertebra and elsewhere in the canal They exerted enough pressure to cause paraplegia Then before they were done they became extraspinal abscesses, and, with relief of pressure in the canal, the paralysis disappeared This does not occur in all cases, but did in these

NEURITIS AND PARALYSIS AS A COMPLICATION OF THE INTENSIVE PASTEUR TREATMENT

J C GEIGER, M D
Assistant Director, Bureau of Communicable Diseases of the California State Board of Health
BERKELEY, CALIF

Remlinger,[1] Stimson,[2] Simon,[3] Hasseltine[4] and Fielder,[5] in a summary of the literature with a report of their personal cases, show the sum total of paralyses following the Pasteur treatment to be 142, with twenty-four deaths With the additional cases described in Table 1, the number of paralyses is increased to 150, without taking into consideration the seven cases reported as neuritis Attention is particularly called to the two cases of optic neuritis heretofore not described in the literature With the etiology of this complication very much in doubt, it is best that one call attention to the seemingly important factors of the cases in this series

TABLE 1—PARALYSES

Case	Diagnosis in Biting Animal Based on	Onset Days After		Site of Involvement	Time of Recovery
	Negri Bodies or Inoculation Observed Symptoms Suspicious History	Bite	Beginning Treatment		
1	+	21	17	Unilateral facial paralysis	Traces 9 months later
2	Treatment taken as a precautionary measure		28	Partial paralysis legs considerable diarrhea present	Six weeks
3	+ No bite supposed cuts on hands	21	15	Paralysis legs partial paralysis arms and face sphincters	Partial recovery 3 weeks later
4	+	24	17	Paralysis both legs cerebrospinal fluid withdrawn and inoculated subdurally into guinea pigs with negative results	Several weeks later
5	+	18	13	Bilateral facial paralysis with involvement of lower limbs sphincters and to a smaller extent the arms prodromal symptoms of extreme nausea and severe local reactions with rise of temperature	Traces 16 months later
6	Dog well treatment taken as a precautionary measure and self administered	12	10	Paralysis both legs and sphincters simultaneous with the beginning of involvement of nervous system there was a flaring up of all previous local reactions with a sharp rise in temperature	Traces 7 months later
7*	Pricked on thumb with needle while administering the Pasteur treatment		17	Paralysis of legs	Several months
8	+		17	Paralysis of legs and sphincters severe local reactions after each injection the paralysis following unusually severe ones no rise of temperature	Reported slowly improving four months later

* Physician

STUDY OF CASES

1 The percentage of involvement of the central nervous system including the cases of neuritis in the series of intensive Pasteur treatments in which these cases occurred, numbering approximately 1,600, was 0 9 per cent This percentage is in excess of what is usually reported, and would lead one to believe that many cases go unrecognized Considering the paralyses alone, the incidence was 1 200 in those treated in this series

2 No children were affected It is of interest to note that Cases 6 and 7 were in physicians

3 The paralysis occured in one person (Case 2) who was not bitten Again, it occurred in one person

[5] Fielder F S Paralysis During Pasteur Antirabic Treatment, The Journal A M A June 3 1916 p 1769

(Case 6) who was bitten, but not by an animal which was rabid

4 Cases 4, 5 and 6 were treated with the same set of virus with fifteen others This virus was checked culturally, aerobically and anaerobically, with sterile results From these cases one would be led to believe that there was some idiosyncrasy on the part of the ones affected *An idiosyncrasy not being a complete* explanation, one would consider the symptoms presented as a result of fixed virus infection

5 In Cases 2, 5 and 6, observed personally, one would be apt to judge the patients as having such temperaments as to predispose to some involvement of the nervous system

6 In Cases 2, 3, 4, 5, 6, 7 and 8, the condition was apparently a myelitis, yet in others the peripheral nerves seemed most involved Facial paralysis alone was noted in one case (Case 1) There is no doubt that bulbar symptoms were present in Case 5 The involvement may be of a selected nature, as shown by Cases 11 and 13

7 In Case 3, though the treatment was discontinued and resumed with no ulterior results, I am convinced from observations of Cases 5 and 6 and the alarming symptoms presented that the continuation of the treatment was bad judgment There must be a border line, so to speak The latter cases around the seventh day of treatment presented definite prodromal symptoms of nausea and temperature In Case 6 the treatment was discontinued for two days, with a return of the patient's condition to normal The resuming of the treatment brought on an immediate and much aggravated return of the initial symptoms coincident with the appearance of the paralysis

TABLE 2—NEURITIDES

Case	Diagnosis in Biting Animal Based on Negri Bodies or Inoculation	Onset Days After		Site of Involvement	Time of Recovery
		Bite	Beginning Treatment		
9	+	24	31	Spasmodic contraction muscles side of neck	Several weeks
10	+	48	45	Spasmodic contraction muscles side of neck	Several weeks
11	+	23	19	Double optic neuritis followed by complete blindness of a few days duration	7 weeks
12	+	34	30	Severe pains left eye later affecting side of face, occurring at intervals	2 weeks
13	+	21	17	Double optic neuritis followed by complete blindness with gradual recovery of vision	Several weeks
14	+			Continuous vomiting	Immediate
15	+	21*	18*	Extreme numbness of fingers and toes with some extension to arms and legs	Several weeks

* Contact

8 One can easily grant that the local reactions observed during the course of the Pasteur treatment are an indication of the individual's hypersusceptibility to foreign proteins Then the flaring up of these reactions simultaneously with the beginning of the symptoms of involvement of the nervous system observed in Case 6, and to a lesser degree in Case 8, is most interesting These cases readily support the anaphylactic theory

9 The shortest incubation period of the paralyses was ten days In one instance it was twelve days, in one thirteen days, in one fifteen days, in three seventeen days, and in one twenty-eight days

COMMENT

There is no doubt that in some persons to whom the intensive Pasteur treatment is administered, 0 9 per cent in our series, taking into consideration the cases of neuritides presented there occurs some involvement of the nervous system, with possible serious results Therefore the intensive Pasteur treatment is not without danger, and warning should be given accordingly

This involvement may be of the nature of a definite myelitis which is most probably rabic The short incubation period as demonstrated in the cases reported here seems characteristic of fixed virus, yet it must be remembered that comparatively as short an incubation period is seen in cases of human rabies,[6] as a result of street virus infection, overwhelming in every instance No single etiologic factor can explain every case, as in Case 6 in my series The patient was not bitten by a rabid animal Either theory—an idiosyncrasy anaphylaxis, or fixed virus—is applicable to this case Though continuation of the Pasteur treatment in some of the cases of paralyses may not appreciably affect the course of the disease, in others it may be fraught with grave danger, as illustrated by Case 6

THE HECHT-WEINBERG-GRADWOHL TEST IN THE DIAGNOSIS OF SYPHILIS

ITS SUPERIORITY OVER THE WASSERMANN TEST IN UNTREATED AND TREATED SYPHILITICS*

R B H GRADWOHL, M D
ST LOUIS

It has taken about one decade to introduce the Wassermann test into the field of diagnosis It is now recognized as one of the most valuable laboratory aids that has yet been brought into routine use It is so nearly specific in differentiating between syphilitic and nonsyphilitic conditions that for all practical purposes we may conclude that a positive Wassermann means syphilis

This reaction is usually performed by competent workers along the lines originally laid down by Wassermann and the so-called Berlin school of serology As a pupil and follower of that school I have insisted on the carrying out of a technic similar in all details to that originally advocated by Wassermann, with the exception of replacing the watery extracts of antigenic substance by one or more of the much superior alcoholic preparations Using, therefore, the so-called "classical Wassermann' with the proper alcoholic antigen, cholesterinized or not as the case may be, I have seen every phase of the development of this reaction, and have watched it from the standpoint, not only of the laboratory, but also with the interest of a clinical observer in syphilis With this experience I have long since come to recognize in this test a splendid method of syphilitic diagnosis and at the same time have come to regard its negative presence in many instances is a sore disappointment in clinching a diagnosis in which almost absolute clinical evidences of the disease were at hand In other words like others, I have long since been forced to conclude that a positive Wassermann is laboratory proof of syphilis, but that a negative Wassermann is by no means a method of proving that syphilis does not exist

---

[6] Geiger J C Human Cases of Rabies in California and Their Treatment California State Jour Med June 1916

* Read before the Section on Genito-Urinary Diseases at the Sixty-Seventh Annual Session of the American Medical Association Detroit June 1916

The Wassermann test, while therefore a boon to us in diagnosis, is at the same time, in other instances, a crushing disappointment How often does this occur? It is almost impossible to estimate accurately the percentage of positives that are to be found in all syphilitic cases that are daily examined throughout the medical world My own experience of nine years in the work entitles me to estimate it in terms of possibly 60 per cent, that is, of all syphilitics examined, including blood and spinal fluid Wassermann reactions, we will get 60 per cent of positive findings in all untreated patients who have passed beyond the primary period

With these figures before us, it might be well to inquire into the meaning of the 40 per cent negatives in manifest syphilitic conditions Is this a fault of the technic or is it due to a temporary or permanent disappearance in the reaction in certain persons and in certain phases of the infection, regardless of the application of specific medication? I would answer as a result of my experiences that it is due partly to the first cause and partly to the second I say this advisedly, because I have been able to add 15 per cent to the column of positives by utilizing another test which eliminates those errors inherent in the test itself I have been unable to add much to the percentage of positives by eliminating faults due to factors inherent in the idiosyncratic factors of the patient or of the disease, unknown factors that make his blood and spinal fluid consistently negative at certain times and under certain conditions I do not include, in the latter statement, however, my use of the "provocative" method of producing positives by means of arsenobenzol injections

About four years ago my attention was called to the method of Hecht and Weinberg[1] in demonstrating the presence of the syphilitic antibody, if such it may be termed, by a method first described by them I had repeatedly tried out methods of making Wassermann tests other than that used by the Berlin school, but in each instance found none of them in any sense superior in point of accuracy to the original method There were, however, certain elements in the method of these workers that logically recommended at least a trial of their methods In first order I might mention the fact that the method utilized unheated serums This is undoubtedly a point of superiority over the Wassermann, which utilizes inactivated or heated serums Heating of blood serum for the purpose of destroying complement unquestionably also destroys part of the syphilitic antibody or substance responsible for complement fixation If this is true, in the presence of a small amount of this substance the performance of a Wassermann test with inactivated serum most certainly will tend to produce a negative result Another explanation of this may be found in the claim of those who believe there are two kinds of syphilitic antibody, one thermolabile, the other thermostable, that in some cases and under certain conditions the thermolabile factor predominates and under other conditions the thermostable Granting that a test were to be carried out while a serum was charged with thermolabile antibody and weak or deficient entirely in thermostable body, inactivation would necessarily destroy the element that would complete complement fixation and give a negative result where a positive should and would have been obtained with an active or unheated serum

This fact seems to have some support in addition to my observation from Vladimir Busila,[2] who showed that both blood and spinal fluid contain two syphilitic amboceptors, one thermostable or unaffected by temperature of 56 C and the other thermolabile, that is, destroyed by that temperature He states that one or both may be present and in various proportions The thermolabile is the first to appear in the blood on syphilitic infection and the last to disappear under treatment When both amboceptors are present, the Wassermann reaction yields a weaker result when the serum is previously heated than when it is not He states also that when the thermolabile amboceptor is present alone or nearly alone, the Wassermann reaction with heated serum gives a negative result, but without heating, a strong positive result The negative blood Wassermann performed with the ordinary technic which includes preliminary heating, is not, therefore, a proof of the absence of syphilitic amboceptor Busila also makes the observation, which is rather interesting, that syphilitic cases with a positive reaction exclusively in spinal fluids are rare, much less common than is generally thought, and includes cases mainly in which the blood amboceptor is exclusively of the thermolabile variety, or nearly so He states, in the light of his own observation, that by the performance of the blood Wassermann with unheated serum one may thus generally dispense with the cerebrospinal fluid Wassermann He further believes that the thermolabile amboceptor often exists alone in cases of latent, inadequately treated or nervous syphilis, and the Wassermann reaction performed with the original technic is thus unavailable, precisely in the cases in which it is most needed

Again it must be remembered that the Wassermann technic does not take into account the presence of natural antisheep amboceptor The presence of antisheep amboceptor in the blood serum of persons depends, it is assumed, on the ingestion of mutton It is impossible to state just how much mutton must be ingested before natural amboceptor appears in the blood We have seen it present in fairly large amounts in persons as young as 12 The amount of this substance varies within wide limits, as we shall see later It is fair to assume that if in the Wassermann reaction one utilizes a certain amount of amboceptor made from rabbit's serum and fails to take into account the amount naturally present, then the balance for the hemolytic system which our titration experiments have established as a prior step to the performance of the actual test is seriously impaired If, for instance, 0 5 c c of a 1 2,000 dilution of rabbit antisheep amboceptor will hemolyze 1 c c of a 5 per cent sheep corpuscle suspension, and already sufficient amboceptor is present in the patient's serum to hemolyze 1 5 c c of sheep corpuscles, as I have frequently noted in my work, then the balance is most seriously disturbed and reliable work cannot be carried out

The method of Hecht and Weinberg was pointed out to me during my stay in Paris, by Leredde particularly The method obviously has much to recommend it in that it utilized unheated serums and took into account the presence of natural amboceptor and natural complement The method was put on trial, and the principles already mentioned readily asserted themselves as eliminating the errors inherent in the classic Wassermann. After working out Hecht and Weinberg's method, I determined on the expedient of estimating the exact amount of complement and amboceptor present in each serum, and utilized only the exact amount of sheep corpuscles hemolyzable by that much amboceptor and complement. In other words, my work with this test added to the accuracy of the "balance" of the hemolytic system. The method which I used and first reported before this Association[3] is as follows:

---

[1] Hecht and Weinberg Wien klin Wchnschr 1909 22, 256

[2] Busila Vladimir Presse med Sept 23 1915

Place in a rack fourteen small test tubes. The first ten of these tubes are used to determine the hemolytic index of the suspected blood. By this I mean the exact amount of hemolytic amboceptor present in the given blood serum. The last four tubes are used in the actual test. Add 0.1 c.c. of fresh unheated patient's blood serum to each of the first ten tubes. Then add decreasing amounts of normal salt solution to these tubes, beginning with 1 c.c., then 0.9, 0.8, 0.7, 0.6, 0.5, 0.4, 0.3, 0.2 and 0.1 c.c. to the succeeding nine tubes. Next add increasing amounts of fresh 5 per cent. suspension of sheep's blood, starting with 0.1 c.c. and ending with 1 c.c. Place the rack in the water bath for one-half hour. The tube which last shows complete hemolysis constitutes our "hemolytic index"; if it is Tube 4, our index is 4, because this tube had received 0.4 c.c. of sheep's corpuscles to be added to the last four tubes. The first three tubes (11, 12 and 13) constitute the tubes for the actual test, while the last tube in the rack (Tube 14) serves as our serum control tube. Tubes 11, 12 and 13 receive therefore the patient's serum, the proper amount of sheep's corpuscles dependent on hemolytic index, rising strengths of antigen, but no complement and no amboceptor. Tube 14 receives only sheep's corpuscles, but no antigen.

In my technic I use 0.1 c.c. of a diluted antigen determined by titration in tube 11, 0.15 c.c. antigen in Tube 12 and 0.2 c.c. in Tube 13. In order to equalize the volume of fluid in all these tubes, I add 0.2 c.c. normal saline to Tube 11, 0.15 c.c. to Tube 12, 0.1 c.c. to Tube 13 and 0.3 c.c. to Tube 14. The tubes are then agitated and placed in the water bath for half an hour. These last four tubes are filled at the time I make the additions to the first ten and are left with them in the water bath for one-half hour for fixation of complement; the rack is then taken out and the hemolytic index computed. If the index is low, say from 1-4, I add 0.1 c.c. of sheep's blood to the last four tubes. If the index is between 5 and 7, I use 0.15 c.c. sheep's blood to the last four tubes; if between 10 and 15, I use 0.25 c.c.; if between 15 and 18, I use 0.3 c.c., and if between 18 and 20, I use 0.35 c.c. If the patient's serum has an index below 3, I regard the reaction as of doubtful value. If it is above 3, I regard it as absolute. The reaction is read off exactly as in the Wassermann, that is, inhibition or noninhibition of hemolysis. If the amount of complement or natural antisheep amboceptor is very low, we can add the proper amount of guinea-pig's serum or rabbit's immune serum, ascertained by preliminary titration.

The particular advantage of this test is the fact that we are dealing with unheated serums, avoiding the chance of the development of complementoid substances. I wish to state that the Hecht-Weinberg-Gradwohl test has never been found negative in any blood serum which showed a positive Wassermann, but it has frequently been found positive in blood serums that show a negative Wassermann. Thus, its advantage can readily be seen.

Having worked out the technic, I have consistently followed it up with a close comparison with the classic Wassermann. In every test carried out by me for complement fixation diagnosis of syphilis I have performed both the Wassermann and the Hecht-Weinberg-Gradwohl. Many of these tests were performed without any knowledge of the clinical history in advance, and my reports were unhesitatingly given to my clinical consultants, sometimes showing a positive in both tests, sometimes showing a negative Wassermann and a positive Hecht-Weinberg-Gradwohl, sometimes showing negative both, but never showing a positive Wassermann and a negative Hecht-Weinberg-Gradwohl. At first I was astonished at the frequency of the "dissociated reaction," by which I mean the negative Wassermann and the positive Hecht-Weinberg-Gradwohl. Later I lost my astonishment and came to the conclusion that the method I used in eliminating the factors of errors inherent in the Wassermann had thoroughly justified me for the additional time spent on it. We found that in no instance where we obtained a positive Hecht-Weinberg-Gradwohl and a negative Wassermann was our work at fault or our serologic diagnosis a surprise to the clinician. We must confess that there are still certain cases of syphilis in which both tests were negative which were really syphilitic, as proved by true clinical manifestations and later the appearance of positive reactions in one or both tests at a subsequent examination. These were invariably cases of latent syphilis in robust individuals. We wish to add, too, that the use of cholesterinized antigens does not measure up in accuracy to the use of the Hecht-Weinberg-Gradwohl test as a serologic test for syphilis. We have carried out both Wassermann and Hecht-Weinberg-Gradwohl, and have utilized all the different antigens now in common vogue. We have lately tried out the use of cholesterinized human heart antigen in an endeavor to compare the results obtainable with this method to those obtainable with a noncholesterinized antigen in the Hecht-Weinberg-Gradwohl technic. We must announce that the Hecht-Weinberg-Gradwohl frequently gave undoubted positives when the cholesterinized human heart antigen in the straight Wassermann technic failed to do so. In other words, our positives with the Hecht-Weinberg-Gradwohl cannot be explained on the basis of increasing the *sensitiveness* of the antigen; they can be explained only on the basis of the elimination of the factors at fault already enumerated. Furthermore, I wish to be understood as stating that when I speak of negative Wassermann and positive Hecht-Weinberg-Gradwohls, we do not mean a *faint inhibition* in the latter and a *complete hemolysis* in the former. The results are astonishingly different and striking, on the one hand a clean-cut negative Wassermann, on the other a definite and distinct, positive Hecht-Weinberg-Gradwohl.

A recent publication by Sellards and Minot[4] alludes to the fact that the writers in fourteen cases in only 134 found natural amboceptor in the amount of two or more units. They also mention that where they depended on natural sheep amboceptor no hemolysis occurred and there was no apparent explanation for this lack of hemolysis except the inefficiency of the natural amboceptor. These statements, while based on an absurdly small number of cases and under conditions unknown to us, are so utterly at variance with our findings and our previous statements that we feel it necessary to dwell on them at some length here. Our personal experience now with something like

[3] Gradwohl, R. B. H.: The Hecht-Weinberg Reaction as a Control Over the Wassermann Reaction, THE JOURNAL A. M. A., July 18, 1914, p. 240.

[4] Sellards and Minot: The Antagonistic Action of Negative Sera upon the Wassermann Reaction, Jour. Med. Research, May, 1916.

5,000 comparative Wassermanns and Hecht-Weinberg-Gradwohls show that at least 98 per cent of the people examined for complement fixation have some amount of natural antisheep amboceptor present This amount, expressed in terms of "hemolytic indexes," that is, amount of sheep corpuscle suspension in tenths of 1 c c hemolyzable by 0 1 c c of serum, varies between the limits of 1 and 20 For instance, the accompanying table, compiled from our complement fixation work from May 1, 1915, to April 30, 1916, shows the number of cases, the total hemolytic indexes and the average

NUMBER OF CASES, TOTAL HEMOLYTIC INDEXES, AND AVERAGE

Month	Cases	Total Hemolytic Indexes	Average Number of Units of Natural Antisheep Amboceptor
May	236	485	2+
June	245	810	3+
July	208	901	4+
August	222	986	4+
September	215	1 301	6
October	216	1 312	6
November	221	1 600	7
December	213	812	3+
January	256	1 610	6
February	254	1 090	7
March	262	1 146	7
April	229	780	6
Total	2 777	Total average	5

In other words, the average beginning May 1915, of units of natural amboceptor present was 2 plus, running up to an average of 7 in November and declining to 6 in April, 1916 A number of times we have found an index as high as 15 The highest we have found was a case recently with 20 Our figures for previous years run approximately the same as those for 1915-1916

In what class of cases and under what conditions are we liable to find the Hecht-Weinberg-Gradwohl positive and the Wassermann negative? We might say that in cases in all periods of syphilitic infection is this finding likely to be found We have found manifest secondary syphilis with a negative Wassermann and a positive Hecht-Weinberg-Gradwohl We have found it again in so-called latent syphilis, in cases of tabes dorsalis, in tertiarism I am referring now to untreated cases In cases of congenital syphilis, we have found it time and again Every Wassermann worker is familiar with the frequent negatives found in this group of cases We have in general found it present in 15 per cent more cases than the Wassermann, irrespective of the period of the disease or whether treatment had or had not been instituted Leredde has called attention to the "dissociated reaction" in ocular syphilis

For the purpose of illustrating the character of cases and the circumstances under which we have obtained what we term a "dissociated reaction," that is, a negative Wassermann and a positive Hecht-Weinberg-Gradwohl, I shall quote the following histories from a large number in our records

Case 1 (8542)—Patient of Dr Jost Treated from December, 1915, as follows Six-tenths gm salvarsan followed by mercurial (gray) oil 1 grain once a week up to Jan 6 1916 Then intravenously 0 6 gm salvarsan followed by weekly injection of mercuric salicylate 1½ grains, up to Feb 4, 1916, then 0 6 gm salvarsan intravenously followed by weekly injections of mercuric salicylate, 2 grains March 4, 0 6 gm salvarsan intravenously Patient disappeared from service, and returned, April 2, expressing a belief that he was cured Blood at the time gave a negative Wassermann, positive Hecht-Weinberg Gradwohl

Case 2 (8024) —Service of Dr Hauck This case came under observation, December, 1914, for a neglected tertiary lesion affecting the vomer and tissues of the posterior nares, decided necrosis with odor of necrotic bone Wassermann was + + + + Patient was put on mixed treatment with four intravenous injections of neosalvarsan, mixed treatment with tonics, continued to date Subsidence of all symptoms, area of necrosis all healed over March 18, 1916, negative Wassermann, positive Hecht-Weinberg-Gradwohl As result of these findings, patient was continued under treatment

Case 3 (6805) —Service of Dr Crowley This man was exposed in August, 1912, when he was 19 years of age Chancre appeared at some time after two weeks He first came under observation the latter part of November of that year The first of December the cutaneous eruption was present He used inunctions of mercury till the first of February, 1913 From that time until the middle of December he took yellow mercurous iodid Then for two months he used inunctions again From the middle of February, 1914, till October, 1915, he took yellow mercurous iodid faithfully From the middle of October till January 5 he took no treatment January 5, Wassermann was reported doubtful only because of the clinical history A single dose of salvarsan was given, March 1 and a second Wassermann was reported negative At this time the patient was advised to discontinue treatment till about the first of January, and then have a Wassermann made Owing to the illness of the attending physician, this was not done, and the patient began to imagine all sorts of things, one being that he had infected his whole family His mental condition became so bad that he insisted on having another dose of salvarsan, and this was administered, Feb 1 1916 On the 9th he brought his father to the office and insisted that a specimen of his blood be sent to the laboratory for examination This was done and was reported from our laboratory under the date of February 12 negative in both reactions His own blood was sent in February 16, and was reported negative Wassermann and positive Hecht-Weinberg-Gradwohl He has received no further treatment, although he has been advised to do so Had a mild attack of grip during March that worried him considerably

Case 4 (3495) —Patient first came under observation at the age of 22 Had been infected at the age of 17 Infection in this case occurred in August 1909, manifestations mild, secondary eruption mild Began treatment Sept 15, 1909, of yellow mercurous iodid, from 1 to 4 grains daily, continuing until May, 1910, then six injections in gluteal muscles (one injection weekly) of 10 per cent mercuric salicylate in liquid petrolatum, each injection 4 minims This was followed by 3 to 6 yellow mercurous iodid pills daily ⅓ grain each, also solution of potassium iodid, about 30 grains daily for three months No further treatment until March and April, 1912, when one injection of mercuric salicylate same as above was given weekly for the two months, followed by no treatment until August 27, when 0 6 gm salvarsan was administered intravenously No further treatment was given October, 1913, Wassermann negative Jan 30, 1914, Wassermann negative Aug 31, 1914 Wassermann negative, Hecht-Weinberg-Gradwohl positive It may be also of interest to know that since then this patient had an injection of 0 6 gm neosalvarsan about May, 1915, then about September, 1915 Wassermann showed negative, then, March 1, 1916 we made test Wassermann, negative, Hecht-Weinberg-Gradwohl positive

Case 5 (4476) —Service of Dr Johnson When patient came under observation she had had syphilis of five years' standing Later had syphilitic baby At time of examination no signs of syphilis Results negative Wassermann and positive Hecht-Weinberg-Gradwohl

Case 6 (5130) —Service of Dr Phillips This was a case of beginning tabes with incontinence of urine and severe headaches He had been treated twenty years previously for a short time for a suspicious sore We found a negative Wassermann and a positive Hecht-Weinberg-Gradwohl

Case 7 (3293) —Service of Dr Boyne Man, History of exposure ten days previously Typical lesion on glans. No treatment before examination. We found negative Wassermann and positive Hecht-Weinberg-Gradwohl, 0.9 gm. of salvarsan given intravenously the day following this 'dissociated reaction." Lesion disappeared rapidly within seventy-two hours. Two weeks later neosalvarsan again given. Patient refused further treatment. Was married subsequently, and had an apparently healthy child.

Case 8 (3254).—Service of Dr. Winter. Woman, aged 32, came under observation, July 15, 1908. Had been married two years and had had one child previous to her marriage by her husband. Was unable to carry three subsequent pregnancies to term. Her husband was syphilitic, and had been under treatment. Patient took yellow mercurous iodid pills for about two years faithfully, with the result that she gave birth to a healthy child in 1910. In July, 1914, we found an examination of the blood gave a negative Wassermann and a positive Hecht-Weinberg-Gradwohl. She was found to be suffering with a septic endocarditis, of which disease she died in August, 1914.

Case 9 (8255).—Service of Dr. Caldwell. Woman came under observation, April 7, 1916, some weeks after losing her only child. This child, which was only 14 months old, had been ill only a few days. Patient was extremely nervous, could not sleep or eat. She had been married nine years. First baby had lived twelve days, had sores on body. Then followed two miscarriages and then the child which had lived only fourteen months. Family history showed that mother had four miscarriages before raising a child, and two of her sisters have each had a miscarriage. She made the remark that none of them had ever been able to raise a boy. Father now at the age of about 65 has kidney trouble, and has been suspected of having tuberculosis for several years. Patient had a very bad case of pyorrhea, which she said had run on for years. Skin on hands and at elbows was dry, and edge of tongue was red. Had frequent attacks of diarrhea, appearance of pellagra. Husband a big, healthy fellow, who denied all knowledge of syphilis. Only treatments given her were two injections of sodium cacodylate. This made some improvement. April 18, we obtained a negative Wassermann and a positive Hecht-Weinberg-Gradwohl. Patient's husband denied syphilis, and blood examination showed negatives in both tests. Patient continued on mercuric chlorid intravenously injected. This was a case of hereditary syphilis. Dr. Caldwell states that he was indebted to the Hecht-Weinberg-Gradwohl for the diagnosis; otherwise he would have considered this a case of pellagra.

Case 10 (2931).—Service of Dr. Darner. Patient came under observation with eruption on chest. Diagnosis, syphilitic leukoderma. History of a chancre six years previously, with very small amount of treatment with pills. Wassermann at that time was positive. Present observation is made six years after initial sore, and at this time the findings are negative Wassermann and positive Hecht-Weinberg-Gradwohl.

Case 11 (6817).—Service of Dr. Lyon. Patient came under observation with a mucous patch and an infection. History of a primary sore. Our findings were a negative Wassermann and a positive Hecht-Weinberg-Gradwohl. The mixed infection yielded to specific treatment.

Case 12 (6268).—Service of Dr. Galloway. Patient came under observation at the age of 54. Diagnosis was locomotor ataxia. Patient denied syphilis, but admitted gonorrhea. Attended the wife in her first confinement in 1895. Child syphilitic, and died in about a week's time. Advised both patients to take treatments, but they refused. Attended the wife in her second confinement in 1896, when she again had a syphilitic child which died in about a week. Then the husband consented to take treatment at this time but continued only a short time because he had no clinical symptoms, and showed no scars, glandular enlargements, or other proofs of infection. Again confined the wife who had a third syphilitic child in 1897 but which recovered under mercurial inunctions and is alive and well today. Mother had been treated two months previous to birth of last child. After this confinement the husband again consented to take treatment, and continued it for about one year. Treatment was with yellow mercurous iodid, and later with red mercuric iodid and potassium iodid. He was urged to continue treatment but he refused. About six or seven years ago he complained of general physical weakness, loss of sexual power and occasional pains in legs. Examination showed Argyll Robertson pupil, Romberg sign, and absence of patellar reflex. Under treatment of red mercuric iodid and potassium iodid, with strychnin intercurrently, he has improved subjectively, and continues at work. Our blood examination, Nov. 27, 1915 showed negative Wassermann and positive Hecht-Weinberg-Gradwohl.

Case 13 (4826).—Service of Dr. Rice. Patient had had a syphilitic infection some eight or nine years ago. Has been under treatment at intervals since then. She was not receiving any treatment at the time the laboratory finding was made but certainly had an infection, also stricture of the rectum which was divulsed some two and one half years ago, and dilation was kept up for a few months. She returned a short time ago and the rectum was again divulsed and she was put on antisyphilitic treatment since which time she has apparently been doing first rate, but there is no question that she had a syphilitic infection a number of years ago.

Case 14 (6572).—Service of Dr. Neel. Patient and her husband were infected in 1907. Treatment with mercury and potassium iodid was given for several years with pronounced success. In the latter part of 1915 he exhibited symptoms of the disease and had a positive Wassermann. He has been relieved by treatment. His wife exhibited no symptoms of the disease but showed a negative Wassermann and a positive Hecht-Weinberg-Gradwohl.

Case 15 (2869).—Service of Dr. Parrish. This was a case of marked tertiary syphilis with no previous treatment. Six months before treatment we found a negative Wassermann and a positive Hecht-Weinberg-Gradwohl. Marked improvement after intravenous injection of salvarsan.

Case 16 (7950).—Service of Dr. Fischer. History of old syphilis. Diagnosis diplopia, made two years previous, which cleared up with mercuric chlorid and potassium iodid. Had two years' treatment. Examination gave Wassermann ++, Hecht-Weinberg-Gradwohl +. Received five neosalvarsans 9 gm. each. An examination made here, Sept. 30, 1915, showed a Wassermann ++ and Hecht-Weinberg-Gradwohl +. Then ten injections of salvarsan were given. A third examination showed a negative Wassermann and a positive Hecht-Weinberg-Gradwohl. General result apparently excellent. Still continuing treatment.

Case 17 (2599).—Service of Dr. Bassett. This patient first came under observation in April, 1913, with the initial sore on the lip. The examination of blood done at this time gave a positive Wassermann. One intravenous injection of salvarsan was given, with internal treatment for seven months, given, not continuously but interruptedly, when all medication ceased. The following April the patient returned, complaining of sore throat. No patches were observed. The patient simply showed a pharyngitis which did not improve with gargles and applications. Another specimen of blood was submitted to us and showed a negative Wassermann and a positive Hecht-Weinberg-Gradwohl. A second dose of salvarsan was then given intravenously and the patient was treated until Dec. 1, 1915.

Case 18 (2144).—Service of Dr. Flader. This patient came under observation, Jan. 22, 1914. On examination a large syphilitic ulcer was found over the right scapular, mucous patches of the mouth and tongue, and an ulcerated condition of the mucous membrane of the nose. He had been under the usual mercurial treatment, previously for about two years, which is about eight years ago. His primary lesion dates back about six years from the time he first consulted Dr. Flader. His treatment consisted only of mercury and potassium iodid by mouth, and there was no other treatment given. Jan. 9, 1914, 0.6 gm. of salvarsan was given intravenously, and six days later all the lesions of mouth, back and nose had disappeared, and to date there has been no return of the trouble or any other evidences. He claims he will take no further treatment unless the evidences of the disease manifest themselves. Blood examination made here showed Jan. 28, 1914 negative Wassermann and positive Hecht-Weinberg-Gradwohl.

Case 19 (5056).—Service of Dr. Thierry. This was a case of imbecility due to hereditary syphilis. Wassermann negative; positive Hecht-Weinberg-Gradwohl.

Case 20 (6231) — Service of Dr Thierry This was a case of mental deficiency due to hereditary syphilis Wassermann negative, Hecht-Weinberg-Gradwohl positive

Case 21 (4978) — Service of Dr Pauley This patient's family history was negative His previous venereal history showed gonorrhea in May, 1911, July, 1912, and June, 1913 Jan 7, 1915, he complained that he had had severe headaches for about one week They improved somewhat under salicylate, but returned later April 1, 1915, he was confined to bed with fever and swelling on both frontal sinuses, also severe headache Feb 12, 1915, he said he had had a blood test made, which was positive February 20, he was given salvarsan, and three mercury injections at intervals He returned, March 28, 1915, and told Dr Pauley what had been done The laboratory findings at this time April 25, 1915, showed a negative Wassermann and a positive Hecht-Weinberg-Gradwohl May 8, 1915, 0 4 gm of salvarsan was given Then he received from 2 to 2 5 c c of a 1 per cent benzoate solution In May, June, July and August he received, respectively, twelve, nine, nine and two injections August 22, he reported that his bowels had not moved for three days, and he had had about five or six chills August 24, he had a chill at 11 a m, followed by fever, 5 30 p m his fever was 102 7 and his pulse 107 August 25, at 9 a m his fever was 99 2 and his pulse 96, at 5 40 p m his temperature was 100 7 and his pulse 90 Blood examined microscopically showed what we thought to be plasmodium, but owing to staining not being good, the question was doubtful At no time were there any eruptions or mucous patches, but the lymphatic glands were enlarged, and there were severe headaches Sept 23 1915, he lifted heavy weights, and slipped Testicle swelled and became very painful On the following day the testicle was swollen more, and the bowels moved at 11 a m, September 23, and then nothing would make them move until 4 30 p m, September 29 The patient was slowly improving when he left the hands of Dr Pauley

Case 22 (6491) — Service of Dr Gradwohl This patient has been under two years' continuous treatment, having received four injections of salvarsan with periodic intramuscular injections of mercury In the absence of all symptoms the patient still shows a negative Wassermann and a positive Hecht-Weinberg-Gradwohl

Case 23 (3168) — Service of Dr Gradwohl In August, 1913 patient came under observation with a history of syphilis of two years standing Had had only six months' treatment by mouth Showed mucous patch Gave strong positive Wassermann and Hecht-Weinberg-Gradwohl at the time He was kept under continuous mercury and salvarsan treatment Six salvarsans and weekly injections of mercury were given with proper intervals of tonic treatment for one year Later he showed negative Wassermann and positive Hecht-Weinberg-Gradwohl This case has been continued, and only in the past two months has shown negatives in both tests

Case 24 (8211) — Service of Dr Gradwohl Infection three months ago Treated with pills Shows a negative Wassermann and positive Hecht-Weinberg-Gradwohl At this time the patient is profusely covered with macular syphilids, and also numerous mucous patches in his mouth

Case 25 (6453) —Service of Dr Gradwohl Shows a negative Wassermann and a positive Hecht-Weinberg-Gradwohl in December, 1915, eight months after initial lesion and after two salvarsans had been given with no other treatment It is interesting to note that after intravenous injection of salvarsan, January 26, 1916, he showed a Wassermann + + + + and a positive Hecht-Weinberg-Gradwohl ("reactivation")

Case 26 (8204) —This patient came under observation with a primary sore followed by a secondary eruption He had had previous to my observation three salvarsans, and fifty-six intramuscular injections of mercury He now presents himself two and a half years after with chancre recurrens At this time he shows a negative Wassermann and a positive Hecht-Weinberg-Gradwohl Under treatment the chancre disappeared, but the reaction persists (May, 1916)

Case 27 (3634) —This case gives a history of primary sore one year previously He has no visible indication of syphilis, but complains of dizziness Examination of blood at this time shows negative Wassermann and positive Hecht-Weinberg-Gradwohl Has been continued under treatment to relieve his symptoms Up to date one year after that he showed strong positive Wassermann and positive Hecht-Weinberg Gradwohl This is evidently a "positive fast" individual

Case 28 (5531) — Patient of Dr Jost Contracted syphilis twenty-seven years ago Had treatment for a period of two years with pills, spent three to six weeks at Hot Springs each year up to six years ago Now complains of a swelling in right testis Wassermann negative, Hecht-Weinberg Gradwohl positive

Case 29 (4992) — Service of Dr Jost Husband contracted syphilis six years ago (during his married life) Patient's history negative, no symptoms, no treatment Wassermann negative, Hecht-Weinberg-Gradwohl positive

Case 30 (6065) — Service of Dr Jost Treatment 0 6 gm salvarsan intravenously followed by sixty-two injections of sodium cacodylate intravenously, 10 grains each, during a period of four months Wassermann negative, Hecht-Weinberg-Gradwohl positive

Case 31 (6064) — Service of Dr Jost Came under observation, Oct 20, 1915 No history, symptoms or treatment Blood test made to verify showed positive Hecht-Weinberg-Gradwohl given by his child Wassermann negative Hecht-Weinberg-Gradwohl positive

Case 32 (8278) — Service of Dr Jost No history, no symptoms, and no treatment Syphilis papulosa mucosae oris Wassermann negative, Hecht-Weinberg-Gradwohl positive

Case 33 (3060) — Service of Dr Jost Came under observation, June 18, 1914 Contracted syphilis, June, 1912 Treated with pills for seven months Spent two and a half weeks at Hot Springs June 16, 1914, complained of nocturnal headache and loss of weight, and had large syphilitic sore on left leg Wassermann negative, Hecht-Weinberg-Gradwohl positive

Case 34 (4865) — Service of Dr Jost Patient came under observation with large ulcerated area on left leg 3 inches below knee Has had some treatment on and off for past two years No history Wassermann negative, Hecht-Weinberg-Gradwohl positive

COMMENT

The group of cases in which the amount of natural amboceptor in human serums seems to play a definite role in making a Wassermann appear negative and a Hecht-Weinberg-Gradwohl positive comprises the following

1 Cases of ocular syphilis

2 Cases of visceral syphilis, particularly of the liver and heart

3 Cases of syphilis that have received intensive but inadequate treatment

4 Provocative cases in which we are seeking to revive a Wassermann in suspected cases

5 Cases of monosymptomatic tertiaries

It is my belief that this test is far superior in every respect to the Wassermann in point of delicacy of "control" of treatment Heidingsfeld[5] speaks of the superiority of this test in estimating the finest shades of any remaining trace of the disease in cases under treatment, while he maintains that the Wassermann used in this way estimates only the coarse, early improvement This to my mind expresses exactly my own position based on my experience with the test in cases under treatment I have noted that the vigorous institution of antisyphilitic treatment, except in the case of the "Wassermann-fast" subject, quickly reduces a positive Wassermann to a negative Not so with the Hecht-Weinberg-Gradwohl, however Long after the Wassermann has become negative and the case very properly still held to the specific treatment, this reaction persists The reduction of the Hecht-Weinberg-Gradwohl from positive to negative under treatment is far more significant to me as a proof of successful therapeusis than is the Wassermann Another observation from my experience with this test which might also be mentioned here is that when the Hecht-Weinberg-Gradwohl becomes negative as a result of the intensive treatment that is needed to bring this about, it seldom lapses back to positiveness In other words, the Hecht-Weinberg-Gradwohl when negative after being persistently positive in untreated syphilis is the "consummation so devoutly to be wished by the syphilologist" I of course do not wish to go on record as stating this as a proof positive of "cure," but I do insist that it has a greater value when repeatedly negative than has a Wassermann under similar conditions

---

[5] Heidingsfeld Serology and Diagnosis of Syphilis New York Med Jour April 8 1916

CONCLUSION

I wish to state also that the Hecht-Weinberg-Gradwohl in my hands has been a far better check or control of the Wassermann than the use of any of the controls now in vogue The so-called borderline Wassermann reactions, if truly positives, will show a strong Hecht-Weinberg-Gradwohl A supposedly borderline positive Wassermann that shows a clearly defined and complete hemolysis in the Hecht-Weinberg-Gradwohl tubes is not a borderline at all, it is a spurious reaction and should be thrown out of consideration There is no better way to control the accuracy of the Wassermann than the use of this test on every blood submitted for examination While originally advocating this test, therefore, as a control over the Wassermann, I feel at present that it has attained the dignity of something more than a mere "control" over the classical test It should take precedence over this test by virtue of its greater accuracy and be accepted as such wherever it is used Outside of the extra amount of time necessary in making the test, there is no argument against its widespread and continuous use in the serologic laboratory The extra amount of labor is more than compensated for by the greater amount of information obtainable I do not recommend it, therefore, solely as a control Rather do I speak of it as a far better test than the Wassermann except in the 2 per cent of cases that have no hemolytic index In this small group the Wassermann must remain our ally In all other cases we could, indeed, eliminate the Wassermann, and lose nothing by so doing It is only in deference to those who cling to the Wassermann that I continue to place it ahead of the Hecht-Weinberg-Gradwohl in my reports To my mind it has long since been passed in the race by the Hecht-Weinberg-Gradwohl, and is bringing up a bad second

No negative Wassermann test to my mind is worth while unless backed up by a negative Hecht-Weinberg-Gradwohl When both are negative, which occurs in 25 per cent of syphilitic cases, according to my statistics, then recourse must be had to the various other methods of the clinic and the laboratory, for the inclusion or exclusion of any remaining trace of the disease

928 North Grand Avenue

ABSTRACT OF DISCUSSION

Dr M L Heidingsfeld Cincinnati A year and a half ago I took up the study of the Hecht-Weinberg serologic examination as modified by Dr Gradwohl with a great deal of skepticism I was thoroughly imbued with the idea laid down by Wassermann and his confreres that the Wassermann serologic examination was the test par excellence, that all modifications had certain fallacies that might lead to serious error, and that the Wassermann itself could never err on the unsafe side, namely, we could never have a positive Wassermann and no syphilis present if carefully and consistently carried out All the modifications, the Noguchi and the Hecht-Weinberg as originally laid down, were regarded by Wassermann and his co-workers as possible pitfalls I have used the modification as set forth by Dr Gradwohl for a year and a half, and I can confirm everything he has said This modification is absolutely trustworthy and reliable I do not know of a single instance where I have had a positive reaction in which syphilis could be excluded definitely In this respect it is as trustworthy as the Wassermann itself I have always been a strong convert to serologic control I will admit that there are many who are opposed to that idea The Wassermann and its modifications have fallen into considerable disrepute in my judgment a very unfair and unjust disrepute I believe that the serologic examination as laid down by Wassermann himself, if all the precepts are carefully carried out, the controls properly made, reagents carefully and properly prepared and the various steps standardized and properly performed, the reaction is absolutely trustworthy and reliable I can say equally as much for the Hecht-Weinberg To treat a case of syphilis without a serologic control is very unsatisfactory and unscientific These controls give us a wealth of information that we otherwise would not have, whether the case is progressing favorably or unfavorably, and how soon the treatment should be repeated, whether or not the same remedy should be used, or a change made to some other remedy, whether or not early marriage can be countenanced or discouraged The Hecht-Weinberg as modified by Gradwohl gives us more information Very often cases of syphilis which are strongly positive to the Wassermann become Wassermann negative in thirty to sixty days after salvarsan treatment but remain positive to the Hecht-Weinberg (Gradwohl), for six months or longer These cases, therefore still have latent *syphilis from a* Hecht-Weinberg (Gradwohl) standpoint, whereas from a Wassermann standpoint they appear to be clinically and serologically negative These are the cases that are prone to relapse unless treatment is energetically pushed Cases which are serologically negative to both the Wassermann and Hecht-Weinberg (Gradwohl) are not so prone to relapse Exceptionally they also relapse if the case is indefinitely withdrawn from treatment and observation Relapses in this class, however are the exception, rather than the rule and if they are controlled by monthly Hecht Weinberg (Gradwohl) serologic examinations, any tendency to relapse can be recognized early and brought under more prompt control than otherwise In my experience I have also often noted a positive Hecht-Weinberg (Gradwohl) and negative Wassermann, but I have never observed a negative Hecht-Weinberg and a positive Wassermann This in and of itself shows that the Hecht-Weinberg (Gradwohl) modification is a much more sensitive test for syphilis than the Wassermann

Dr A I Wolbarst New York I have had a number of examinations of serum made for me by Dr Gradwohl with the Hecht Weinberg modification not so much as an original test for syphilis but to check up the results of other laboratories with the Wassermann test It has been my experience that you can go into any laboratory in this country and take your choice as to whether you are going to get a positive or a negative report on any serum submitted Some laboratories will give you a positive and some a negative report on the same serum taken at the same time and presented under the same conditions Serologists are working hard trying to devise some way by which the thirty-five or forty sources of error which have been revealed may be obviated I was very glad to employ this Hecht Weinberg test as modified by Dr Gradwohl, and to see which of the laboratories I was dealing with furnished the more accurate reports and I am very gratified to say that, considering the clinical manifestations of the case the Hecht-Weinberg appears to me, as far as my experience goes, to be far more delicate and far more reliable than the straight Wassermann In any number of cases where I have had contradictions positive and negative in the same serum where I have had a negative Wassermann given to me in a case of undoubted syphilis, the Hecht-Weinberg has been positive I have never seen an instance of a negative Hecht-Weinberg with a positive Wassermann I feel that in any case in which we are in doubt as to whether the Wassermann we are getting is to be depended on, the Hecht-Weinberg Gradwohl modification gives us an amount of information which is of the greatest importance It ought to be used more generally than it is

Dr **Leland Boogher**, St Louis I have no faith in the Wassermann test being infallible A minus Wassermann does not necessarily mean no syphilis I always feel safer when I have the two tests made In all the cases I have had it has been interesting to notice that where there was a negative Wassermann and a positive Hecht-Weinberg I had made a diagnosis of syphilis There are many cases where I suspect syphilis and have the tests made, and it is sometimes very satisfactory to find that the diagnosis has been correct As to the accuracy of the Hecht-Weinberg test, I am only speaking from the standpoint of the clinician, but I have always felt that it was possibly a more delicate test than the Wassermann I like to have both tests made on my patients

Dr **Lewis E Schmidt**, Chicago I agree with Dr Gradwohl and Dr Heidingsfeld I wish to cite several instances where the Wassermann was negative two and three years after the last treatment Under those circumstances we are prone not to give further treatment In several instances we found the Hecht-Weinberg test positive two or three years after the last negative Wassermann In other words, during that entire period of time the Wassermann was negative, yet at that late period the Hecht-Weinberg was positive, which set me thinking as to the necessity for further treatment, particularly in this series of cases

Dr **M L Heidingsfeld** Cincinnati The Wassermann is also invaluable when used in conjunction with the Hecht-Weinberg (Gradwohl) It reveals the finer shades of early improvement which the Hecht-Weinberg in and of itself fails to reveal Moreover, the two controls serve as a check on each other, eliminating, in a measure, any possible error of a purely technical nature Each serves as a check on the other in this respect The Hecht-Weinberg is positive is always strongly positive, never weakly positive as the Wassermann, when it shades off in the stages of early improvement

Dr **Carl C Warden**, Ann Arbor, Mich There is no question that theoretically and practically the Hecht-Weinberg is an improvement on the Wassermann The great difficulty lies in two factors, one the complement and the other the antigen The antigen is the thing We are extremely unfortunate in the Wassermann reaction The antigen is very indefinite It has been classed as a lipoid, but there is no substance in it on which we can really lay our hand I believe with further studies on the toxicity of normal serum, of the periodic disappearance of the complement in normal serum and with improvements in the syphilitic antigen, that we will be able to pick up those positive reactions better than we do now

Dr **Benjamin Gruskin**, Chicago I have used the Hecht-Weinberg test in over 200 cases I have nothing but praise for it as a control, and still call it a control The clinician as well as the laboratory man is sometimes at a loss to interpret the so-called borderline cases Some laboratory men, in a case that gives a slight positive reaction will say, "I am not going to condemn that man because he gives a very faint positive reaction' Others, again, are very liberal in pronouncing a case syphilis when they see the slightest degree of nonhemolyzed cells Really, one test is not sufficient in a doubtful case so any additional control is of great value I would rely more on a positive Wassermann than on a positive Hecht-Weinberg and I would rely more on a Hecht-Weinberg negative than I would on a Wassermann negative, but I believe by employing both one can check up and make a standard which can be called 'faintly positive" or "strongly positive" What is needed more in laboratory work is to know exactly what "one, two, three or four plus" positive is What one man will call one plus another will ignore altogether However, the two tests used together by a close observer, who has his own standard for what he calls "one, two or three plus positive will certainly be a great aid to the laboratory man as well as to the clinician Another factor regarding the Hecht-Weinberg which must be taken into consideration is that the serum must be sent to the laboratory immediately This is hardly possible with a serum that is sent from out of town, which necessarily would be at least a day old In these cases one may inactivate the serum, as for the Wassermann, and go through with the Hecht-Weinberg in the usual manner, plus additional complement

Dr **R B H Gradwohl**, St Louis This is a far easier test to perform than the Wassermann This test uses no artificial amboceptor and no artificial complement It requires no guinea-pigs, it requires no injection of rabbits It requires fourteen tubes, which may look startling, but does not mean very much work It requires one tenth of a cubic centimeter of the patient's serum in each tube We then estimate how much complement and amboceptor are present. In this test we do not have to bother very much with what are called borderline Wassermanns With this test, they are either positive or negative It is in this respect that this test has been of most value in my hands, because any Wassermann worker will confess that these borderline cases have been our bete noir Often we could not tell a clinician whether a given case was positive or negative It was a "borderline" *In these instances the Wassermann instead of being a help* was a great hindrance This test eliminates that If you get a "borderline" Wassermann you will get a strongly positive Hecht-Weinberg, if it is a spurious "borderline' Wassermann case you will get a negative Hecht-Weinberg If it is worth nothing else, it is worth a great deal to serologists from that standpoint

CANCER OF THE PROSTATE *

GRANVILLE MacGOWAN, MD

LOS ANGELES

Cancer of the prostate may be defined as a process of new growth or malignant degeneration of previous growths taking place primarily at any place within the capsule, or within that portion of the urethra which communicates directly with the glandular tissue of the prostate by way of its ducts

For some reason, unknown and unexplainable with our present knowledge, that glandular group, lying between the submucosal urethral tissues and the posterior capsular surface, the so-called posterior lobe, is, or appears to be, the most frequent site for development of cancer of the prostate It is claimed by Young and his school that the exceptions to this are very rare We admit the value of this careful research work, but to us it seems that its conclusions are forced It is often manifestly impossible to determine, when the disease is widely distributed, exactly which is the oldest part, but we do know that it has been seen primarily in any anatomic portion of the gland, and in atrophied, apparently normal, and hypertrophied prostates As there is no definite, unvarying and finely marked syndrome characterizing cancer of the prostate, the diagnosis must be determined largely by exclusion In approaching a prostate suspected of pathologic change, the examiner must keep before him the mental image of the average normal organ about the size of a horse chestnut and of much the same shape, its upper border concave, convex toward the anus, bilobar, but not always symmetrically so, with a groove perpendicular to its long axis between these lobes where the tissues are markedly thinner, showing the course of the urethra through the organ, usually rounded from side to side, but not infrequently flattened like a truffle from its lateral abrupt borders toward its center, elastic, relatively smooth, only moderately sensitive to digital pressure, and movable to a degree from side to side and from above downward.

* Read before the Section on Genito Urinary Diseases at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

* Because of lack of space all of the individual case reports are omitted in The Journal. The complete article appears in the Transactions of the Section and in the author s reprints

* This paper and the paper by Drs Young and Frontz, which follows are parts of a symposium on the prostate. The remaining papers by Drs Gardner Crenshaw and Squier and the discussion will appear next week

Chronic departures from this type, processes to be diagnosed differentially from cancer, are:

1. Increase in size and density and the presence of hyperesthesia: chronic parenchymatous prostatitis, either total or partial, with groups of hyperplastic glands, oftentimes with capsular adhesions.
2. Long continued, low grade, deep seated abscess of the prostate running its course without the symptoms of frank infection.
3. Primary tuberculosis of the prostate with its massive induration.
4. Stone situated well within the glandular tissue.
5. Atrophy of the glandular tissue with interstitial inflammatory changes.
6. Contracture of the bladder neck.
7. Sarcoma.

Let us see how these differ from, and how, in their symptoms, they resemble cancer of the prostate.

Chronic Parenchymatous Prostatitis.—The exploring finger encounters an obstruction bulging into the rectum from the region of the prostate. This may be symmetrical with a distended capsule, or the inflammatory process may be localized in one or more groups of glands in one lobe, or scattered irregularly throughout the whole organ. Such a prostate is tender on pressure and often very hard. Gentle massage always appreciably alters its consistence, reduces its volume and expresses a succus prostaticus which contains pus, phosphatic debris, lecithin granules, bacteria, epithelial cells of normal shape and staining capacity, and often dead spermatozoa. The mesial groove is still preserved, and a metallic instrument introduced into the bladder can be readily palpated throughout the whole length of the prostatic urethra. Examination of the posterior urethra by a water urethroscope or an open endoscope shows congestion, edema, pus exuding from enlarged glandular ducts, and often cysts and polypoid growths. Increased frequency in urination is often present, and there may be hesitancy and lack of power to the stream, and even residual urine, usually due to the presence of polypi or edema in the posterior urethra. All of the symptoms improve under treatment.

Simple Hypertrophy.—In adenomatous or fibromuscular enlargement of the prostate we palpate through the rectal wall an exaggerated prostate, an organ out of bounds. The enlargement is often symmetrical, but, just as frequently, larger on one side than on the other; it is movable when it can be grasped bimanually: the rectal tissues slide over it, or it slides away from the rectal tissues. There is a certain elasticity approaching the normal to the tumor, or tumors, if the adenomatous elements prevail; any outgrowths beneath the bladder, and up along the seminal ducts are soft and elastic. If there has been much long continued inflammation accompanying the process, and the fibromuscular changes outbalance the glandular, the tumor masses may be indurated, but they are never hard, like sole leather, bone or ivory, and they are not adherent to the surrounding parts. Massage reduces their volume temporarily, and if there has been no infection, expresses a succus prostaticus that contains masses of epithelial cells, undergoing fatty degeneration, abundant lecithin bodies, amorphous calcium phosphates and carbonates, a few leukocytes, many sympexia, and often live spermatozoa. If the patient has advanced to catheter life, infection has almost invariably taken place, and then the microscopic field shows, in addition, pus, bacteria and often a few red blood cells.

The cysto-urethroscope shows a congested, but flexible, posterior urethra with encroaching smooth surfaced whitish adenoma, enlarged follicular ducts, sometimes diverticula, few or many polypi and small cysts. The shaft of the instrument may usually be palpated from the anus to the bladder neck.

Chronic Abscess.—Long continued, low grade, deep seated abscess of the prostate taking its course without fever and without general infection, but with cachexia and deep seated boring pain, may give rise to the mistaken diagnosis of cancer. I had one such case in 1897 in the Los Angeles County Hospital.

> A man, aged 60, had suffered for six months with deep seated pain in the perineum, with increasing difficulty in micturition, and finally complete retention. There were no other symptoms excepting a marked cachexia, constipation and loss of weight. On rectal examination, we found a huge tumor, stone hard and unyielding, occupying the whole pelvic floor. This was believed to be without any doubt, a malignant growth. A perineal exploratory operation was undertaken. Just as the apex of the prostate was opened, there was a gush of pus, and the exploring finger entered a capsular sac, entirely empty of prostatic tissue. This sac surrounded the urethra, which coursed through it, without any communication with it.

Binney reports a somewhat similar case in a much younger man, the exploratory operation being made suprapubically.

Stone in the Prostate.—This need not occasion any diagnostic difficulty, as the Roentgen ray easily differentiates for us.

Prostatic atrophy of the glandular and muscular tissues, with chronic interstitial inflammatory changes causing loss of elasticity in the prostatic urethra, and contracture of the bladder neck, is often painful and simulates cancer very closely at times. The ring of indurated tissue entirely surrounds the urethra and prevents the shaft of the cystoscope at the neck being plainly felt by the exploring finger. In these cases, the best criterion of the nature of the malady is microscopic slides of the tissues removed by the punch.

Tuberculosis.—The occasions on which an error in diagnosis between cancer of the prostate and tuberculosis are possible should not be many, for tuberculosis is usually seen secondary to a similar affection of one or both epididymides with scattered nodules, of only a moderate degree of induration, and early vesical irritability, or else follows a descending urinary tuberculosis of long standing, tubercle bacilli being present in the urine, with caseating destruction of the prostate, from the urethra out, and ulceration along the urethral channel, demonstrable by the urethroscope, and accompanied by a urethral discharge, usually free of micro-organisms. Once, and once only, in an experience of more than thirty years, have I seen a case of primary tuberculosis of the prostate, in a man of 30 in which, symptomatically and by clinical history, we were dealing with a carcinomatous growth, which on microscopic section and subsequent development, was demonstrated to be tuberculous.

Sarcoma—This is more elastic and of less painful development, and is more likely to occur in youth, though I have had two cases in men past 50 years of age

FREQUENCY OF CANCER OF THE PROSTATE

Socin and Burckhardt[1] in 1902 assembled 120 cases, the total material reported in the literature of all languages up to that time During the past thirteen years it has been learned that cancer of the prostate is relatively common, and in great clinics, where the specimens removed in operating for prostatism have all gone to careful microscopic examination, the following figures have been returned Reports from the Necker Clinic place the frequency at 15 per cent, from the Johns Hopkins, at 28 per cent, the Mayo Clinic, at 15 5 per cent, and Mansell Moullin,[2] at 25 per cent This gives an average of about 20 per cent, or one case in five, which probably closely approximates the true figure, though the returns of the pathologic institute at Munich are still higher, nearly 40 per cent, or one in two and one half cases, a figure which should cause much thought to an unskilled operator The youngest patient who has come to my notice was 17 years of age, reported by Gardner and Cummings[3] A number of cases have been recorded in persons past 80

CARCINOMA

In the analysis of the appended cases, it will be easily seen that extensive carcinomatous infiltration of the prostate may exist without the presence of any of the symptoms commonly relied on to make a differential diagnosis between this condition and prostatic hypertrophy, for vesical retention and irritation is common to the two There is no change in the urine that may be relied on as significant of cancer of the prostate Judd[4] seems to think that an unusually low specific gravity is found in these cases, but this is true of any chronic obstructive disease of the total urinary tract, and bears no relation to cancer How much more difficult must it be to determine an accurate diagnosis when the whole process is entirely intracapsular and confined to a deeply situated glandular group well removed from both the urethral and the rectal zones When retention supervenes on vesical irritation, in months instead of years, after difficult and painful urination, mostly at night, when infiltration bullet-like, boardlike, leather-like or ivory-like is found in the prostate of a man who presents no symptoms of active syphilis or tuberculosis, and whose blood gives a negative Wassermann reaction, when the capsule of the gland has become adherent to the anterior pelvic fascia, or the fascia of Denonvillier, and the perirectal fascia, but the rectal tissues are no longer movable on it, and it has lost its motility in the pelvis, and the prostatic image to the sense of touch has become blended with that of one or both of the seminal vesicles, without the presence of acute inflammatory symptoms, when the central groove is blurred or lost, in the anterior two thirds of the prostate to the finger examining through the rectum over a steel instrument in the urethra, and added to this is loss of strength, and pain in the back, pain in the rectum, edema of the lower extremities, and neuralgia along the course of the sciatic, obturator or crural nerves, it is safe to make the diagnosis of cancer of the prostate

The stiffening of the walls of the posterior urethra gives to the introduction of the instrument to the bladder a peculiar resistance which is not that of the blocking caused by adenomatous nodules, but more of insufficiency of tubular space It is not unusual for a metallic or silk catheter or a cystoscope to creak in its passage through the narrowed and stiffened urethra, as if it were passing unoiled through a tube of harness leather An inlying catheter is never well borne Hematuria may or may not be present It always occurs early when the cancer starts in the prostatic urethra I have met two cases of this character recognized by means of the urethroscope In both the prostate was easily enucleated entire, there were no adhesions and no nests in the peripheral tissues Both had prompt local recurrence and metastasis, and each patient died within six months Hematuria is much more likely to occur in a congested hypertrophied prostate, but its origin should always be investigated with a cystoscope of small size of the irrigating type which will get by almost any obstruction in the posterior urethra if the stream of salt solution is turned on when the instrument is passing through the bulb

A urethroscopic examination of the posterior urethra should always be made when cancer of the prostate is suspected, as pointed out by Braasch[5] If the disease is on the anterior wall, it can be seen as shown in Case 3 of my appended report, if in the posterior lobe, the floor is elevated so that the sulcus, posterior to the colliculus, is wholly obliterated Bullous edema of the bladder neck or trigon is frequently observed The size of the prostate is no argument for or against its malignancy Small, hard, painful prostates, occurring in men in the fifth and sixth decades of life, should always be viewed with suspicion, as should also abnormal tenderness or pain in the rectum without the presence of hemorrhoids or inflammatory affections of the rectal walls or of the prostate Metastases often take place early to the lymphatics and the bones in men past the age of 45 Without a clear picture of lymphocytosis, pernicious anemia, Hodgkin's disease, tuberculosis, local infection or syphilis, any chronic swelling of the lymph glands, or persistent ostalgia should cause investigation of the prostate for cancer

Edema occurring about the penis, the rectum or the lower extremities, without definite renal or cardiac pathology, should always make one thoughtful of a probable carcinoma of the pelvic organs, and if, in the male, it be accompanied by pelvic pain and vesical irritability, should be sufficient cause to incite examination of the prostate for a primary cancer causing metastasis to the pelvic lymph glands and pressure on the iliac veins

Metastasis takes place at times undoubtedly while the disease process is confined within the capsular wall, but it is usual after the rupture of the capsule, an occurrence signaled by the cessation of nerve pressure and the sudden temporary relief from pain, for it to spread, especially when the origin is in the posterior lobe, to the seminal vesicles and the pelvis, the bladder being attacked nearly always late and through the posterior wall close to the ureteral mouths, where it is in contact with the loose cellular packing about the seminal vesicles This extension takes place along the ejaculatory ducts and the accompanying lymph channels, as was first pointed out by Young[6]

[5] Braasch Factors Which Determine the Advisability of Prostatectomy St Paul Med Jour January 1915

Lundsgaard[7] reports a huge extensive lymphoma of the neck, operated on and found to be adenocarcinoma, in which, postmortem, a chain of fibroplastic carcinomatous enlarged glands led directly to a left-sided cancer of the prostate, in which the adenocarcinomatous parts lay in nests separated from each other by thick layers of fibromuscular tissue which had given no local symptoms during the patient's life time

According to Salinger,[8] cases of metastases have been observed in all of the gland groups of the head, neck and trunk, including the axillary I have seen metastatic nodules in the liver and in the splenic flexure of the colon from the prostate, others have found them in the suprarenal capsule, kidneys, spleen and pleura Von Recklinghausen first directed attention to the great frequency of secondary cancer in the bones, metastatic from the prostate, and this has become so much a matter of common knowledge with surgeons that it may be accepted as a rule, that no case of apparent primary carcinoma of a bone, in a man past middle life, should be operated on without investigation of the prostate gland, so as to avoid unnecessary surgery Yet sometimes the primary nodule in the prostate is so small and deeply placed that it is only discovered postmortem

When the patient comes for consultation with bloody foul-smelling urine and dysuria, terrifying tenesmus, or entire retention, with great difficulty in passing a catheter through the urethra and great resentfulness to its presence there, so that it can be retained for only short intervals, or not at all, with pains radiating out from the pelvis in all directions, with edema of the legs and perineum and a stone hard immovable prostate, *tender to the touch, not to be differentiated from* the surrounding pelvic organs, and enlarged superficial inguinal glands, the diagnosis of cancer of the prostate is easy but useless to make, for it is long past the time at which any valuable relief can be given to the patient

When is the time for diagnosis of cancer of the prostate, and what are the means to attempt its cure or relief? The time is while the growth of the carcinoma is still confined within the capsular walls of the gland, while we are not yet certain of its nature, while there is yet a chance that the growth may be one of the conditions from which we have to differentiate it The means are the surgical procedure of prostatectomy with complete removal of all the glandular elements, either after the method of Freyer, or that of Young The two give equally good results if performed properly Freyer reports eight cases in which the patients were alive and in good health, from three to ten years after operation, and others in which the results were not so good, but he states that, even though the disease should recur, it is a great consideration to the patient in the interval to be able to urinate normally, thus deferring for months, or even years, the establishment of a permanent fistula

Taking the figures of Albarran and Halle[9] as a basis, in which fourteen out of 100 prostates, apparently normal on removal, proved microscopically malignant, he believes he has operated on 150 carcinomatous prostates in this stage, and he has not known of more than six in which cancer subsequently affected the patient Given that this stage has passed and the cancer is not surmised, but the diagnosis reasonably certainly established, what is the best mode of procedure? The choice then has to be made between as complete enucleation, or dissection, as possible, conducted suprapubically, so as to run no risk of incontinence by destruction of the external sphincter, and subsequent sparking of the capsular fragments with the d'Arsonval current, as I have shown to be feasible and successful, in Cases 5, 6 and 7 of this report, or by the operation described by Young as a conservative partial prostatectomy, removing all the prostatic tissue that can be removed by a dissection on each side, and outside of the urethra, but within the capsule, to delay progress and give for a time relief from retention The ease with which such dissection can be accomplished will depend much on the cancer type These prostates are usually not very large, and if of the epitheliomatous type, they adhere to the capsule and present the same difficulties to removal that small prostates of the fibroid type do, while adenocarcinoma often separates easily from the capsule In rare selected cases, one may attempt total removal of the prostate and its capsule with the urethra beyond the triangular ligament, and the anterior two thirds of the trigon, either by the method described by Young, or by the method described by me As Young advises, such an operation should not be commenced if the trigon is infiltrated, the pelvic or iliac glands enlarged, the seminal vesicles, the membranous urethra, or the muscular wall of the rectum involved, or metastatic foci are known to exist The partial removal of a cancerous prostate, through the perineum, will result in incontinence in 50 per cent of the cases, but if a good free channel is obtained, the patient will live much longer and be much more comfortable, even if he does have to carry a urinal, if he cares for that kind of life I had one patient who lived for seven years, and he seemed to be happy Naturally, in some cases, interference with the knife would cause more rapid spread of the disease and should always be followed by a thorough sparking of the remaining parts with the bipolar high frequency current

When it does not seem wise to undertake any of these measures, or they are rejected, catheter life is the refuge as long as it is not painful or very difficult to pass a catheter When the patient becomes unhappy from pain, or infection supervenes, or recurrent epididymitis occurs, permanent drainage through a suprapubic fistula must be established For this purpose, many apparatus have been devised, the major number of which are cumbersome and unsatisfactory I think I have tried all that have been recommended in the past thirty years, each leaks at times, some, all of the time The cheapest and most satisfactory I have found to be a De Pezzer self-retaining catheter from 20 to 30 in caliber of the French scale, which is to be connected with a glass or metal bottle, carried in a special pocket in the underwear during the day and with a small hot water bag attached to the undershirt at night The bladder can be washed of debris through this tube once or twice a day, with a silver nitrate mercuric cyanid or permanganate solution The tube has to be replaced in from three to six months These

TABULATION OF CASE REPORTS

Case	Date	Physician	Age	Dysuria	Palpation Through Rectum	Cystoscopic Information	Kidney Function	Operation	Complications	Origin	Results	Alive	Metastases
1	11/13	F J Boesche	76	3 months	Some thickening over shaft of cystoscope	Congested bladder	Phthalein intravenous 11 min, 32% first hour	Suprapubic prostatectomy	Hemorrhage	Not clear	Comfortable one year ultimate retention	Yes	Sacral and lumbar vertebrae
2	11/15	MacGowan	63	With retention 3 months	Negative as to cancer	Negative	Phthalein intravenous 7 min 40% first hour	Suprapubic prostatectomy and d Arsonval sparking	Hemorrhage	Acini right lobe	Comfortable one year	Yes	Sacral vertebrae
3	12/13	Hamman	69	With retention 9 months	Negative as to cancer	Vesical outlet changed growths in urethra visible	Urea Marshall test, normal	Suprapubic conservative prostatotomy	None	Superior lobe injury silver catheter	Comfortable six months no return of retention	Died 9/15	Lumbar and sacral vertebrae
4	5/14	Dohman	70	10 years with retention 5 months	Hypertrophy negative as to cancer	Distortion of vesical outlet	Markedly uremic phthalein 17 min 20% first hour	Suprapubic prostatectomy in two stages	None	Acinus anterior lobe	Perfect in every way	Yes	None
5	8/14	Stockwell	76	4 months	Hypertrophy negative as to cancer	Distortion of vesical outlet cystitis follicular abscesses in posterior urethra	Phthalein intravenous 4 min 58% first hour urea, 18 for 24 hours	Suprapubic partial prostatectomy d Arsonval sparking	Stricture of urethra colon bacillus and aureus infection	Apparently anterior lobe injury silver catheter	Perfect in every way	Yes	None
6	10/14	Schnabel	70	6 months	Prostate very hard right vesicle indurated mesial groove normal to neck of bladder	Impossible to introduce cystoscope into bladder	Very uremic phthalein intravenous 20 min 18% first hour	Suprapubic cystotomy drainage 5 weeks prostatectomy d'Arsonval sparking	Multiple calculi stricture of urethra cancer colon	Not clear, wide spread	Perfect as to urination	Yes	Splenic flexure of colon liver pelvic bones, pelvic glands
7	1/15	Morrison	63	6 months	Prostate very hard	Trabecular bladder bullous edema	Phthalein, intravenous 47% first hour urea normal	Suprapubic prostatectomy d Arsonval sparking	None	Not clear	Perfect as to urination and sexual power	Yes	None
8	5/15	Violet	65	6 months	Negative as to cancer	Edema of trigon	Phthalein intravenous 5 min 35% first hour urea normal	Punch operation continuous suprapubic drainage	Colon bacillus infection	Near vesical neck	Strong able to work process retarded	Yes	Not certain

patients live from three months to seven years, and often during the early period lose all pain, put on flesh and gain strength, so that to the ordinary observer they appear to be in robust health In time, the process extending to the bladder mucosa brings ulceration with nerve exposure and hemorrhage, pain, cachexia, the necessity for opium, uremia from ureteral obstruction, and finally death

Radium Cure—There is but one authenticated case of apparent perfect cure of cancer of the prostate by radium cross-firing so far as I know, and that is the one of Pasteau and Degrais[10] The prostatic urethra is an ideal place for the use of radium, but the results so far obtained do not warrant its recommendation as a therapeutic agent

Some instances of what appear to be secondary carcinoma of the prostate are on record in which the distributing focus was the colon I have never met such a case, though I have seen one in which cancer of the descending colon and cancer of the prostate appeared to have developed simultaneously

Pathogenesis—Where it is so manifestly difficult macroscopically to differentiate cancer of the prostate, it is easy to understand how dissension has arisen among pathologists as to the pathogenesis of these growths, and the interpretation of microscopic sections made from them In borderline cases it is very difficult at times to decide without viewing many sections in series When we remember that "a normal acinus is lined with a single or an imperfect double layer of columnar epithelial cells," we have the basis from which we have to calculate our changes Given an abnormal stimulus, a hyperplasia of these cells occurs, and so long as the hyperplasia gives rise to types of cells conforming to those naturally existing in the acini and confined to the acini, producing lawful and regularly arranged progeny of the original cells, no malignant type can be said to exist, but when the hyperplasia is chiefly or exclusively of the undifferentiated cells of the outer row, marked, and their arrangement without alinement in relation to one another and to the basement membrane, lawless, the case is probably malignant, and if the stroma surrounding the acinus is invaded by the epithelial cells, surely so

REPORT OF EIGHT OPERATIVE CASES

I have arranged these cases in tabulated form, giving the ages, previous symptoms, duration, results of rectal and cystoscopic examinations, kidney function, character of operation performed, results obtained, complications and the apparent primary seat of the growth

Five of these patients were over and three of them were under 70 years of age

The one constant symptom was dysuria, which had been noticed in two cases for three months, in one for four months, in three for six months, in one for nine months, and in one for ten years In five (Cases 2, 3, 4, 5 and 8) the results of palpation made through the rectum over the shaft of the cystoscope were negative as to the presence of cancer In Case 1 there was some thickening in the posterior lobe In Case 6 the mesial groove could be palpated readily but the rest of the prostate was very hard In Case 8 the prostate was very noticeably hard over the shaft of the cystoscope Seven patients are still alive

---

[10] Pasteau and Degrais Sur l emploi du radium dans le traitement des cancers de la prostate Jour d urol med et chir, Sept 15 1913

Patient 1 was comfortable for a year but now has dysuria and retention from extension of the growth to the surrounding structures and metastasis Patient 2 was comfortable for a year but now has dysuria Patient 3 was comfortable for six months but died in September, 1915, never having had a return of his retention Patient 4 is alive and in perfect health Patient 5 is in apparently perfect health and has full control of his bladder, there is no evidence either by palpation or by the cysto-urethroscope of cancer in the prostatic cavity or in the bladder Patient 6 has widespread metastases but urinates perfectly Patient 7 is apparently well Patient 8 is alive and comfortable, but wears a suprapubic drainage tube because of the presence of cancer in the bladder wall

---

PRELIMINARY TREATMENT FOR PROSTATECTOMY IN UNFAVORABLE CASES [*]

HUGH H YOUNG, M D
AND
WILLIAM A FRONTZ, M D
BALTIMORE

Twenty years ago the mortality for prostatectomy was estimated at 20 per cent Today in some clinics it is less than 4 per cent What has brought about this marvelous change? More accurate diagnosis and better operative technic have, of course, done much to reduce the mortality — the substitution of accurate operations, under visual control, for destructive procedures done in the dark, being one of the principal factors

But much of the early mortality was due to complications, resulting from conditions existing before operation which were overlooked or neglected In 1898, one of us operated on a patient who came to the hospital in severe uremia A catheter could not be passed, suprapubic drainage was all that could be done, and the drainage afforded worked a seeming miracle In a few days consciousness returned, and within a few weeks prostatectomy was carried out without difficulty and with success Since then we have had a keen realization of the wonderful benefits of preoperative drainage in all prostatic cases in which the kidneys have been impaired by long-standing back pressure

At first we employed suprapubic drainage in all such cases, but before long we came to realize that the same result could be accomplished by an inlying catheter or even by intermittent, regular catheterization One of the most striking of these early patients was a man, aged 76, who was comatose and very septic, catheter drainage and infusion were not sufficient to abate his uremia, so we employed blood letting and simultaneous saline transfusion in the opposite arm, together with salt by rectum After carrying out these strenuous methods for several days, the infection and uremia both disappeared, and in six weeks a prostatic operation was successfully carried out

Employing the knowledge gained from similar experiences, we were the first to advocate systematic preparatory treatment in prostatic work where involvement of the kidneys, heart, etc, was present, and as a result in 1908 were able to report 128 consecutive perineal prostatectomies without a death, two of the patients being over 80 years and forty-three over 70 years of age

In the early years of this work, the physical condition of the patient, presence of high residual urine and evident symptoms and signs of poor kidneys were the principal indexes which guided us in our decision as to when to delay operation and to resort to preparatory treatment The phlorizin test and freezing point were experimented with without much help When the value of phenolsulphonephthalein was first shown in the urologic department in 1910, it was quickly applied to prostatic cases and found to give the index of renal impairment which we had previously been able only to surmise or guess at

As time went on, the desirability and value of additional tests for the blood, heart, etc, have been demonstrated, so that now a complex but remarkably helpful series of routine tests are employed in almost all cases

Too great care cannot be exercised in the study of these cases preliminary to operation Abnormalities of one kind or another are the rule rather than the exception, and the surgeon who disregards or overlooks these danger signals fails to reduce his mortality to the minimum A careful physical examination, which should include a blood pressure reading, is of course essential in every surgical case Of special importance in prostatic hypertrophy is an examination of the urine, the determination of the residual urine and a study of the renal function

If on examination no organic disease is demonstrable, the blood pressure normal, the urine free from pathologic elements and the renal function satisfactory, an early operation can be carried out with the realization that, from a clinical standpoint, the patient is an excellent surgical risk There is one important exception, however, which should be emphasized The presence of a large residual urine, even though there be no infection and the renal function fair, furnishes a considerable risk if operation be performed without preparatory treatment These are patients often with atonic bladders, dilated ureters and varying grades of hydronephrosis, and without preliminary catheterization, the danger of acute uremia and ascending infection is greatly increased

Unfortunately an ideal physical condition is the exception, and the risks may be classified as follows

I CASES WITH RENAL IMPAIRMENT

This is most often due to back pressure, which usually leads to distention of the renal pelves and thinning of the renal cortex, the degree of lesion being dependent on extent and duration of the back pressure In many cases infection has been added to the renal lesion, producing varying grades of pyelitis, pyelonephritis and pyonephrosis In some cases a chronic nephritis is present without demonstrable infection

Renal impairment may also result from cardiac insufficiency To determine this renal impairment our most valuable means is

A *The Phenolsulphonephthalein Test*—Space in THE JOURNAL does not permit any extensive description Our routine is to make one test on admission, if possible with the first catheterization, as important functional changes may occur immediately after that If the residual urine is large we may expect a drop in the kidney function until the kidneys adjust themselves to a catheter life (absence of back pressure) Semiweekly phenolsulphonephthalein tests are taken, and as a rule a steady improvement is shown (see cases) until a stationary period is arrived at

---

[*] From the James Buchanan Brady Urological Institute, Johns Hopkins Hospital

[*] Read before the Section on Genito Urinary Diseases at the Sixty Seventh Annual Session of the American Medical Association, Detroit, June 1916

[*] Owing to lack of space this article is abbreviated in THE JOURNAL The complete article appears in the Transactions of the section and in the author s reprint

If the first phenolsulphonephthalein test is good, the amount of residual urine not great (say, not over 200 c c) and the general condition good, operation is usually not delayed

If the phenolsulphonephthalein test is poor (appearance time over fifteen minutes, excretion first hour under 30 per cent), the patient is put on preliminary treatment while further studies are made

B *Blood Urea*—This is determined in cases with poor phenolsulphonephthalein excretion, and in most of these cases shows no abnormal increase of the urea in the blood In such cases catheter drainage with relief of back pressure will usually result in rapid improvement, as shown by successive phenolsulphonephthalein tests A high blood urea generally goes with a bad phenolsulphonephthalein test and shows a dangerous condition, though this, too, often rapidly disappears on preliminary treatment (catheter, water, etc)

C *Acidosis*—In cases of impending uremia a marked retention of acid salts may be present in the blood This is discovered by determination of the hydrogen ion concentration of the blood or by estimation of the carbon dioxid content of the alveolar air A fair index to the condition may be seen in the amount of sodium bicarbonate required to make the urine alkaline In the normal person 10 gm will render urine alkaline in a few hours

Preliminary Treatment—This may be classified as follows

(*a*) Relief of Urinary Retention This is very desirable when the residual urine is large in amount (over 250 c c) even though the phenolsulphonephthalein test is good In such cases catheterization twice daily for a few days may be all that is necessary If the phenolsulphonephthalein test is still good and the general condition good, and the infection present is not acute (no dysuria, acute urethritis, epididymitis or suggestion of ascending infection, fever, etc , present) prostatectomy may usually be then carried out safely In cases with sterile urine, acute infection is to be guarded against by irrigations and injection of small amounts of 5 per cent argyrol at each catheterization If, notwithstanding every precaution, infection does occur, the patient should be watched several days to see that the above mentioned complications do not occur

Where the residual urine is very large (say, over 400 c c), and particularly when the phenolsulphonephthalein test shows definite renal impairment, catheterization from four to six times daily is indicated to prevent recurrence of back pressure, and allow the kidneys to improve In such cases an inlying or retained catheter may be preferable, particularly if catheterization is difficult or quite painful The catheter should be changed at intervals of from one to three days (depending on infection and irritation), and the urethra should be injected with 5 per cent argyrol and "rested" several hours before a new catheter is inserted A small soft rubber catheter is preferable to a gum coude, but sometimes will not pass The inlying catheter may be closed with a clip or cork and emptied at intervals, or allowed to drain in a bottle, the patient being up and outdoors if possible In very acute urethritis and epididymitis a retained catheter should not be employed Epididymotomy may be required, and intermittent catheterization until acute symptoms subside Sometimes suprapubic drainage is indicated in such cases, but our experience shows that it is certainly not indicated as a routine procedure, and that even patients with severe renal impairment from prostatic back pressure can almost always be got in excellent condition for prostatectomy by catheter drainage

(*b*) Diuresis The use of water in large amounts is very important, to keep kidneys active, expel uremic products, keep down infection and irritation, and assist in restoring good renal function We give usually 6 ounces every hour, 3 quarts daily, especially in cases with lowered renal function In severe cases salt solution by rectum or by infusion is employed — often several quarts daily — with due regard to the heart In severe cases of uremia, transfusion and even simultaneous bloodletting have been employed with almost marvelous effect

(*c*) Urinary Antiseptics Hexamethylenamin is given in doses of 15 grains three or four times daily unless it causes irritation of bladder or gastric disturbance In alkaline urines, acid sodium phosphate or sodium benzoate in large doses (at separate times from hexamethylenamin) is also given In cases of dysuria, methylene blue (1 grain three times a day) may relieve the irritation, though diuresis and argyrol injections usually suffice

(*d*) Treatment of Acidosis In the acidosis accompanying the severer forms of renal destruction, sodium bicarbonate should be given in large doses until the urine becomes definitely alkaline This may be given by mouth or by rectum, but in the advanced cases the best results follow its use intravenously Glucose and lactose, the former by infusion, the latter by rectum, also form a valuable adjunct in the treatment of these cases In these cases and others showing cumulative phenomena, free catharsis is often followed by most beneficial results

As illustrating the splendid improvement in these renal types following the institution of preparatory treatment, these cases are cited

Case 1 —A L R, man, aged 50 was admitted April 14 1915 There had been obstruction of urination of two years duration due to hypertrophied prostate of considerable size Residual urine was 850 c c Phenolsulphonephthalein test appearance time twenty-five minutes, first hour, 8 per cent Blood urea was 1 06 per liter (normal, 0 5 gm) Mitral insufficiency, blood pressure, 210 Preparatory treatment was instituted Remarkable improvement was obtained, as shown in the tabulation

TABLE 1 —PHENOLSULPHONEPHTHALEIN TESTS BLOOD UREA DETERMINATIONS AND BLOOD PRESSURE READINGS IN CASE 1

Date	Appearance Time Min	First Hour %	Second Hour %	Total %	Blood Urea Gm	Blood Pressure
Apr 6						
Apr 8	26	8	6	14	1 06	210/110
Apr 10	18	12	10	22		185/105
Apr 12	20	14	11	25		160/98
Apr 15	19	18	15	33	0 80	170/85
Apr 24	15	24	11	35	0 64	
Apr 29	13	23	12	35	0 55	150/80
					0 47	

The patient was operated on the following day, a perineal prostatectomy being done The convalescence was uneventful and he left the hospital in excellent condition twenty days later

Case 2—E C W, man, aged 47, admitted Sept 30, 1915, with symptoms of urinary obstruction of several years' duration, had *nocturnal incontinence* He was toxic, with marked edema The prostate was very large Residual urine was 1,125 c c, specific gravity, 1 004 No phenolsulphonephthalein during first hour Blood urea 1 gm per liter Preparatory treatment was followed by wonderful improvement (Table 2)

TABLE 2—PHENOLSULPHONEPHTHALEIN TESTS IN CASE 2

Date	Appearance Time Min	First Hour Per Cent	Second Hour Per Cent	Total Per Cent
Sept 30		0	13	13
Oct 2	14	14	25	39
Oct 6	10	12	22	34
Oct 10	10	27	19	46
Oct 15	10	28	16	44
Oct 17	10	20	20	40
Oct 19	10	28	20	48
Oct 24	10	40	19	59
Oct 26	10	37	21	58

The improvement in this case was very striking, the patient gaining daily in strength and putting on 25 pounds in weight during the four weeks' preliminary to operation Perineal prostatectomy was performed, October 27 Recovery was uneventful Patient was discharged well in thirty days

Comment—These two cases showed a marked improvement following the institution of preparatory treatment The first case is one of chronic nephritis with hypertension complicated by infection and back pressure, and shows a gradual increase in the phenolsulphonephthalein output to a point at which it remained stationary The inverse parallelism between the phenolsulphonephthalein and the blood urea is also well illustrated We have noted not infrequently in such cases a marked lowering of the blood pressure following the establishment of free urinary drainage and rest in bed This is rather strikingly shown in this case The second case is apparently one of functional impairment due entirely to back pressure, and shows splendidly the recuperative power of the kidney following catheter drainage, the renal function gradually returning to normal

II CASES WITH CARDIAC LESIONS

The determination of the cardiac risk often involves careful and prolonged study Valvular and myocardial change is often seen in these cases, but so long as the condition is fully compensated, the risk of operation is minimal Where there are signs and symptoms of a break in cardiac compensation, however, operation is absolutely contraindicated and should not be considered until complete restoration of function has been established In these cases, frequent physical examinations, blood pressure records, fluid and urine charts and in the more obscure forms, electrocardiographic studies, are valuable in following the course of the condition

The treatment of a break in compensation, whether it is due to valvular or to myocardial disease, is much the same Rest in bed, digitalis and, in cases in which edema is a prominent feature, limitation of the fluid intake and free catharsis are indicated The surgeon acts wisely in following the advice of a medical consultant in these cases, and at the Brady Urological Institute there is a whole time medical man who has charge of all such cases and the borderline work between medicine and urology

The following cases show the value of preliminary treatment in this type of risk

Case 3—W H H, aged 67, admitted Oct 21, 1913, had prostatic hypertrophy Residual urine was 500 c c Heart was enlarged, irregular, mitral insufficiency Electrocardiogram showed marked hypertrophy of left ventricle Auricles had ceased coordinate contractions and were in a state of *fibrillation Blood pressure was 130 Treatment consisted* of large doses of digitalis, rest in bed, catheterization, etc The improvement in heart was steady and in one month the condition was vastly changed

TABLE 3—PHENOLSULPHONEPHTHALEIN TESTS IN CASE 3

Date	Appearance Time Min	First Hour Per Cent	Second Hour Per Cent	Total Per Cent
Oct 22, 1913	11	30	8	38
Oct 29, 1913	10	45	13	58
Nov 4, 1913	8	40	15	55
Nov 20 1913	9	48	12	60

November 21, perineal prostatectomy was performed Electrocardiographic tracings taken during operation showed only an occasional extrasystole Three days after operation, the pulse again became rapid and irregular, responding promptly to digitalis There was no further irregularity, and the patient was discharged, December 13 An electrocardiogram taken December 20, one week after discharge showed that the heart was contracting in normal manner There was also great improvement in general health and strength

Case 4—A B aged 66, admitted, Dec 1, 1915, had prostatic obstruction for three years, associated with headaches, dizziness dyspnea, cardiac palpitation and angina The pulse was weak cyanotic and dyspneic, the heart was enlarged greatly Presystolic gallop rhythm and systolic blow at apex and base Blood pressure, 165/80 Prostate considerably enlarged Residual urine, 120 c c, specific gravity, 1 016, albumin pus and bacilli

TABLE 4—PHENOLSULPHONEPHTHALEIN TESTS IN CASE 4

Date	Appearance Time Min	First Hour Per Cent	Second Hour Per Cent	Total Per Cent.	Blood Pressure
Dec 2, 1915	15	16	23	39	160/85
Dec 5, 1915	10	39	19	58	165/95
Dec 7 1915	10	40	21	61	140/80
Dec 12, 1915	10	40	18	58	

In addition to the catheter drainage, the preparatory treatment in the case consisted chiefly of digitalis and nitroglycerin for the anginoid attacks The heart compensated promptly, and perineal prostatectomy was successfully carried out, December 13

Comment—These two cases illustrate a rather extreme type of cardiac risk, and it is doubtful whether an immediate operation could have been performed successfully With the return of cardiac compensation, however, the risk was relatively slight, and both patients went through operation remarkably well The blood pressure raising effect of nitrous oxid rather contraindicates its use in these cases, and we are of the opinion that ether is the anesthetic of choice in such cases, but in other cases we almost invariably employ nitrous oxid and oxygen, with a small amount of ether

III CASES WITH CARDIORENAL DISEASE

The study of cardiorenal disease resolves itself into a determination of the relative responsibility of the heart or kidney for the clinical and laboratory findings As has been pointed out, in pure cardiac disease, the impairment of renal function may be the result of passive congestion, and if compensation is established, the renal function returns to normal In these cases, in which the cardiac disease is alone at fault, the phenolsulphonephthalein output is rarely alarmingly low, nor is the retention of urea much above the upper limits of normal Where the burden of responsibility rests with the kidney, however, its functional value, as determined by phenolsulphonephthalein, may approach zero and the urea retention may be at a very high level Marked *improvement as regards the renal and cardiac* condition may follow promptly the institution of catheter drainage and other preliminary measures In such a case the affair is largely a functional one, the renal impairment resulting from urinary obstruction, the cardiac condition being secondary to the renal one

In other cases giving little or no evidence of urinary retention, where the elements of back pressure and infection can be eliminated, changes in renal function fail to keep pace with cardiac improvement, and the condition is one of true nephritis

Many combinations are, therefore, possible, in one instance, the heart alone may be responsible, the improvement in both the heart and kidney running parallel, in another the renal condition is primary, the degree of response to treatment depending on the character and extent of the renal lesion

The question to decide in the treatment of these cases is the factor primarily responsible for the condition If the cardiac disease is primary, rest in bed, courses of digitalis and, in some cases, limitation of the fluid intake may bring about a prompt return of compensation In the cases in which the preponderance of fault lies with the kidney, the establishment of free urinary drainage, diuresis, regulation of the diet, and in the event of urea retention, free catharsis may be of benefit

There will remain, however, a certain number of cases in which the outlook is most discouraging and the treatment long and tedious The forcing of water, so essential a part of the treatment in certain renal types, may be contraindicated by the cardiac condition, and in others, measures directed toward the relief of the heart may be antagonistic to renal improvement

As an example of a rather extreme type of cardiorenal risk, and as showing how prolonged the preparatory treatment may be, the following case is cited

CASE 5—H D C aged 67, admitted Sept 16 1913 had prostatic obstruction ten years, attacks of dyspnea, dizziness headaches, nausea and vomiting, one year, paradoxical incontinence one month, and chronic bronchitis dilated hypertrophied heart, mitral and aortic insufficiency Blood pressure was 175, residual urine 825 c c albumin, casts pus and bacilli

TABLE 5—PHENOLSULPHONEPHTHALEIN TESTS AND BLOOD UREA DETERMINATIONS IN CASE 5

Date	Appearance Time Min	First Hour Per Cent	Second Hour Per Cent	Total Per Cent	Blood Urea Gm per Liter
Sept 16 1913	40	10	5	15	0 820
Sept 18 1913	40	15	5	20	
Sept 21 1913		5	3	8	
Sept 23, 1913					0 980
Oct 8 1913	58	3	7	10	
Oct 16 1913	70	Trace	10	10	
Oct 31 1913	60	9	9	18	
Nov 10 1913	30	7	2	9	
Nov 20 1913					0 800
Nov 29 1913		4	7	11	
Dec 10 1913	20	18	7	25	
Dec 13, 1913	30	12	14	26	0 360
Dec 15 1913	18	14	8	22	

The preparatory treatment in this case was very prolonged and consisted chiefly of catheter drainage, the forcing of water and the use of stimulants as indicated During the first four weeks, the patient was uremic, on one occasion having convulsions To this difficulty were added frequent breaks in cardiac compensation On two occasions the life of the patient was apparently saved by the prompt use of strophanthin and camphorated oil With improvement in the cardiac condition, allowing the use of water in larger amounts, the phenolsulphonephthalein output increased, remaining quite stable, and the blood urea was reduced to within normal limits After thirteen weeks preparatory treatment, a perineal prostatectomy was carried out Recovery was uneventful The phenolsulphonephthalein test on discharge showed an appearance time of twelve minutes, and output for the first hour 30 per cent and second hour 10 per cent

Comment—This case shows what can be accomplished by preliminary renal and cardiac treatment in very bad cases Examination one year after operation showed the cardiac and renal condition still greatly improved

IV CASES WITH HYPERTENSION

Arterial hypertension may exist independently of cardiac and renal disease, and moderate grades of it are seen without any discoverable organic change The condition is most often associated, however, with renal or cardiovascular lesions, and its chief interest in this connection lies in the determination of its causation If the responsibility rests with the kidney, the outlook will depend on the extent of the renal change and the degree of associated cardiovascular disease As a condition per se, it rarely contraindicates prostatectomy, although in the severer forms, particularly when combined with marked arteriosclerosis, the risk of operation may be a very serious one

The use of blood pressure lowering drugs in these cases is often dangerous, and at best the result is transitory Rest in bed and the usual preliminary treatment in cases with associated back pressure symptoms are often productive of permanent results We have seen frequently rather marked cases of hypertension occurring in individuals with long standing urinary retention and the usual back pressure phenomena With rest in bed and catheter drainage, marked lowering of the blood pressure has frequently been coincident with improvement of the renal condition

The following cases illustrate how uncertain the prognosis may be in this type of risk

CASE 6—M E, aged 60, admitted Feb 21, 1916 had prostatic obstruction for six months and vesical calculus No residual urine Bladder capacity 90 c c Specific gravity of urine, 1 016, no casts, faint trace of albumin Appearance time of phenolsulphonephthalein, ten minutes, first hour, 48 per cent, second hour, 15 per cent Physical examination excellent except slight hypertrophy of left ventricle and blood pressure of 200 Patient was thought to be an excellent surgical risk, and prostatectomy was performed, February 28 After the patient's return to the ward it was noticed that he remained unconscious, and examination showed a left sided hemiplegia and evidently a cerebral hemorrhage which occurred during the anesthesia before or during the operation

CASE 7—G R, aged 68, admitted Sept 13, 1913, was perfectly sound in every respect except for hypertension The treatment preparatory to operation was rest in bed and restriction of fluid intake to 1 500 c c The phenolsulphonephthalein tests and blood pressure readings follow

TABLE 6—PHENOLSULPHONEPHTHALEIN TESTS AND BLOOD PRESSURE READINGS IN CASE 7

Date	Appearance Time Min	First Hour Per Cent	Second Hour Per Cent	Total Per Cent	Blood Pressure
Sept 13 1913	22	40	10	50	210
Sept 15, 1913	11	53	15	68	
Sept 16 1913					210
Sept 18 1913					200
Sept 19, 1913					205
Sept 20 1913					210
Sept 21 1913	8	48	18	66	210
Sept 22, 1913					210

Perineal prostatectomy was performed September 22 Recovery was uneventful

Comment—The determination of the degree of risk in a given case of pure hypertension is difficult, if not impossible Advanced grades of cerebral arteriosclerosis may be present with very little change in the peripheral vessels, and a radial artery whose wall is barely palpable is no surety against a cerebral catastrophe That sudden elevation in blood pressure may result in fatal hemorrhage should constantly be borne in mind, and for this reason we believe ether to be preferable to nitrous oxid as an anesthetic in these cases The complication cited in the first case, however, is relatively uncommon, and in our series of nearly 1,000 perineal prostatectomies, it has occurred but twice

V CASES WITH INFECTION

The majority of patients requiring operation for the relief of prostatic obstruction have urinary infection and in a recent series of ninety-four cases, the urine of sixty-six, or 70 per cent, contained pus and microorganisms The mere presence of bacteria in the urine without localizing signs is not alarming, but the occurrence of an acute process cannot be watched too carefully Acute infections of the epididymis and urethra immediately call for a suspension in the use of the retention catheter The majority of these cases can be tided over the course of the infection by interval catheterization, and the condition clears up promptly as a rule In some instances the process is progressive, and if drainage of the bladder is necessary, a suprapubic cystostomy should be done Many of these acute infections are secondary to the retention catheter, and can be prevented if sufficient care is exercised Frequent changing of catheter, the substitution of interval catheterization in some cases, urethral and vesical injections of 5 per cent argyrol and irrigations will do much toward diminishing the frequency of these complications

As a fair statement of what can be accomplished by means of careful preparatory treatment, we think we may take the first years' work in the Brady Urological Institute from January, 1915, to January, 1916 During this time there were ninety-four cases in which prostatectomy was carried out, ninety by the perineal route and four suprapubically, with only one death, this patient being 93 years of age and dying of cerebral thrombosis on the thirteenth day after operation An analysis of these cases is as follows The average age was 67, the youngest 46, and the oldest 93 years of age There were three over 80, fifteen over 75, twenty-three over 70 During this period every patient who came to the hospital suffering with pronounced obstruction from prostatic hypertrophy was operated on, so that there was no selection of cases Fifty-three cases required considerable preliminary treatment, the longest being a period of sixty days, five cases required preliminary treatment over four weeks, nine over three weeks, twenty-three over two weeks, thirty-nine over one week, and eleven less than one week The following analysis of the phenolsulphonephthalein records shows the splendid improvement which was obtained by means of preparatory treatment

In the series of ninety-four cases, fifty-one, or 54 per cent, required preliminary catheter treatment, and of these, thirty showed on admission an output of less than 30 per cent phenolsulphonephthalein for the first hour, and nineteen an output of less than 20 per cent The preparatory treatment varied from four to sixty days, and at the time of operation, of these thirty cases, only ten had a first hour phenolsulphonephthalein of less than 30 per cent, and only one less than 20 per cent

There were numerous cardiac lesions found in this series, both myocardial and valvular in character, and two extremely severe, one, a man 75 years of age, with a very bad heart from myocarditis, and another aged 66, whose case had been cited above In regard to the cardiac cases we may say that almost every case, even those of very severe degree, can finally be got in sufficiently good condition for perineal prostatectomy under ether anesthesia, this anesthetic on account of its stimulating effect being preferable to anything else in cardiac cases We are firmly convinced that these patients should not be operated on by spinal anesthesia

High blood pressure was moderately common in this series of ninety-four cases, there being forty-two over 150 and fifteen over 170 In four cases the blood pressure was 200 or more, yet operation was successfully performed in each of these cases Considerable care was taken in preliminary treatment in these cases, as described above

A survey of these ninety-four patients, many of whom were very aged and infirm, shows that with proper care, perineal prostatectomy may indeed be called a benign operation This, we believe, is due to various facts The wound is extravesical, the drainage dependent, and the absorption of septic materials unquestionably less Abdominal distention and other complications, which are not infrequently present after suprapubic prostatectomy, are very much less frequent after the perineal operation The ability of the patient to get out of bed in a very few days, and the ease with which hemorrhage can be controlled, either by ligation of bleeding points at operation or packing, are very greatly in favor of the perineal route These facts are mentioned because we believe that in severe cases, the choice of operation has almost as much to do with the ultimate result, particularly the mortality, as the preliminary treatment

CHICAGO

Fractures of the os calcis are due to two factors direct violence by a fall on the sole of the foot, and a strong contraction of the gastrocnemius, making a sudden upward pull, thereby putting tension on the Achilles tendon We have to deal here with a short fragment attached to one of the strongest muscles of the body, tending to displace it gradually even further than it was carried by force of the direct violence, and in the same direction (from *C* to *D*, Fig 1) This short posterior fragment forms the posterior third or quarter of the longitudinal arch of the foot (*E* to *H*), and, when displaced upward, lowers the arch of the foot (changing *CG* to *DG*), at the same time stretching or tearing the bowstring which holds this arch normally (*GH*) and is attached to the anterior surface of the posterior fragment of the os calcis, running forward to its fan-shaped anterior attachment around the metatarsal articulations The result of the tearing or laceration of the plantar fascia, which was referred to as the bowstring of the arch of the foot, results in a flattening of the anterior portion of the arch of the foot, which, in turn, and in conjunction with the lowering of the posterior portion of the arch due to fracture, allows the foot to evert (bringing *E* and *A* nearer to each other), thereby bringing the fractured surface of the os calcis upward and outward toward the external malleolus (*A* to *B*)

This results, if allowed to progress to the deposition of callus around the fracture, in mass of callus forming just behind and below the external malleolus (between *A* and *B*), pinching the soft tissues between two bony surfaces, and giving severe pain The foot, thus being everted, causes the weight line which normally should fall on the middle metatarsal bone to fall on the first metatarsal bone or inside of it, further throwing a strain on the already lacerated ligaments of the longitudinal arch and causing further flattening of the foot

Fortunately Nature has provided an easy way to rid us of the upward pull of the gastrocnemius by making the Achilles tendon in such a way that it heals readily after subcutaneous tenotomy without further surgical procedure, and is firmly united by the time the fractured bone has become solid

It is a simple procedure to introduce a tenotome under the skin and completely sever the Achilles tendon, thereby ridding us of the only tendency to displacement of the posterior fragment, which can now be replaced with the assurance that there will be no displacement on account of muscular action If the fracture is impacted the foot should be placed over an orthopedic block (Fig 2) with one hand above the heel and the other over the metatarsal bones, and the impaction broken up, forcing the heel and toe down and toward each other This increases the arch and at the same time moves the fractured anterior surface of the posterior fragment downward and inward, increasing the distance between it and the external malleolus The fragment replaced, the foot can then be put in a plaster cast in strong inversion (Fig 3) further removing the line of fracture from the external malleolus Before the cast is dry, the base of the thumb should be placed in the arch of the foot (Fig 4) holding the soft plaster up against it In this way there is an overcorrection, bringing the ends of the lacerated plantar fascia into apposition, and allowing the traumatized ligaments of the sole of the foot to contract before the cast is removed

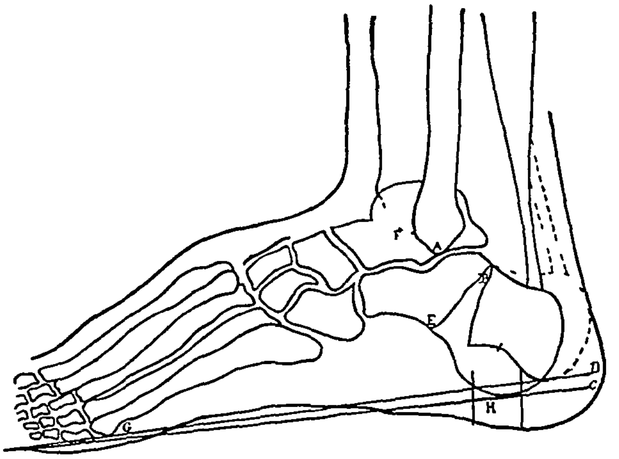

Fig 1—*A* external malleolus *B* site of fracture and callus formation which is brought close to *A* by a combination of falling of the arch and eversion of the foot *H* to *G* attachments of plantar fascia lacerated at time of fracture of the os calcis *C* to *D* distance the arch is lowered when the posterior fragment of the os calcis is pushed up An eversion of the foot causes the internal malleolus *F* to be brought nearer the ground it also throws the weight line drawn from the anterior superior spine of the ilium through the middle of the patella to fall over the first metatarsal or inside of it rather than on the middle metatarsal as it normally should

The cast should be allowed to remain on the foot for at least four weeks, and the patient admonished not to rest any weight whatsoever on it until two months have elapsed When the cast is removed, dry or moist heat applications with expert massage should be instituted to increase the circulation in the ligaments and fascias of the sole of the foot, establish motion in the ankle joint, and loosen the adhesions about the Achilles tendon At the end of the two months the patient should be encouraged to put weight on the foot gradually, care being taken to notice whether the callus around the fracture is solid enough so that it will not allow angulation of the posterior fragment

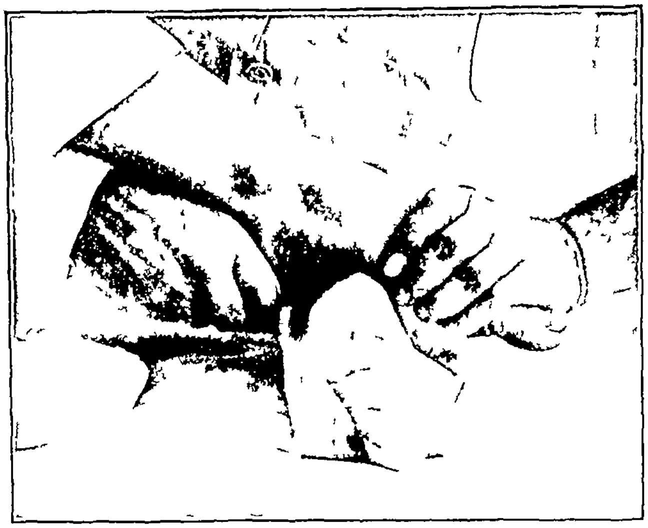

Fig 2—The proper position of the hands on the foot in bringing the heel and the toe close together over an orthopedic block and the reduction of fracture of the os calcis If impaction is too firm to be broken up in this way the foot should be placed in a sand bag and the posterior fragment struck a sharp blow with another sand bag which will relieve the impaction

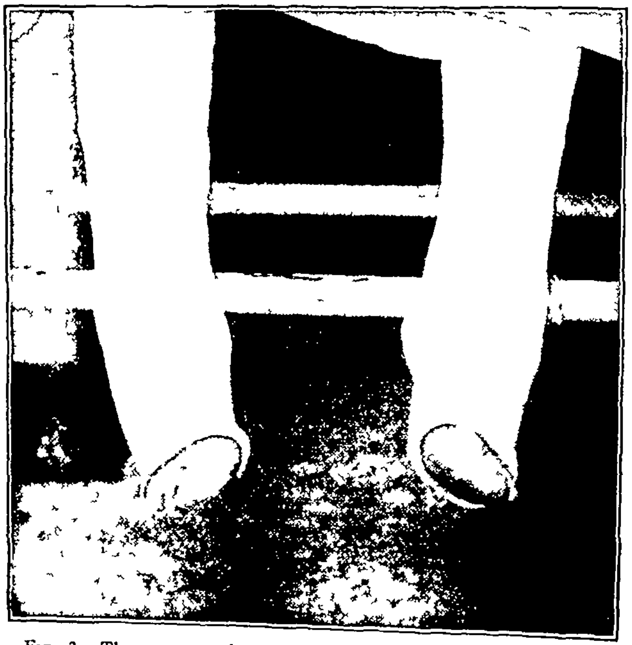

Fig 3—The position of the feet in plaster Strong inversion with pressure under the instep

The ligaments in the sole of the foot being weak and having a tendency to allow the foot to evert, the sole and heel of the shoe should be built up from one-eighth to one-quarter inch on the inside of the foot, so that the body weight will fall on the flat outside portion of the foot and not overtax the weakened ligaments of the arch The arch may be supported by adhesive plaster strapping in conjunction with a felt pad either held on by the straps or sewed on an insole, and placed in the shoe in such a manner as to support the longitudinal arch (Figs 5 and 6)

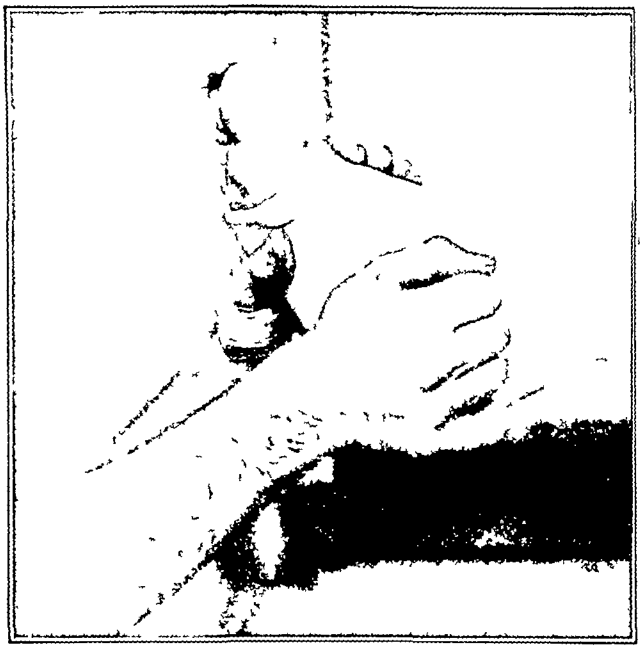

Fig 4 —Proper position of the hands in inverting the foot and putting pressure under the arch while plaster is still soft Care should be taken that the hand on the outside of the foot in this case the left, does not press the plaster against any bony points

The felt pad has proved much more satisfactory in the treatment of a weak foot than the metal plate, since it allows a moderate amount of strain to fall on the fascia, and being a spongy, elastic substance, it constantly massages the sole of the foot and increases the circulation The metal plate acts as a rigid splint, relieving the ligaments of all strain, and thereby allowing them to weaken and to atrophy from lack of use

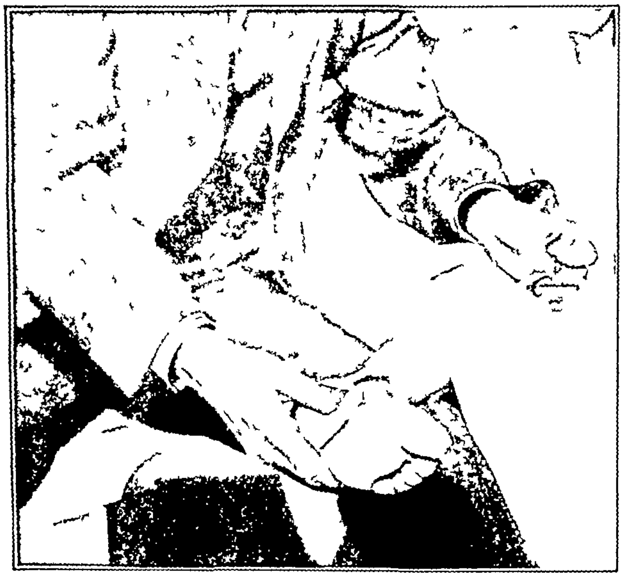

Fig 5 —Inversion of the foot with felt pad under the arch for support showing the method of using adhesive plaster

Under this treatment, which has been extremely successful in my hands, we should have no permanent disabilities from fractures of the os calcis There is no fracture in the body known which is more commonly overlooked and which will give more painful disability than a fracture of this kind, unless the mechanical details of the treatment are looked after carefully, and there is none easier to treat or which gives better results than this fracture, if promptly diagnosed and correctly treated It is essential to examine with the Roentgen ray every patient who has sustained a fall on the sole of the foot, especially when there is pain and swelling underneath and posterior to the external and internal malleolus

No fear should be felt in severing the Achilles tendon, since this structure has been cut subcutaneously by numerous men over a period of many years and practically never has failed to unite and refunctionate even in persons over 60 years of age, and it is absolutely impossible to hold the short posterior fragment of the fractured os calcis in proper apposition to the anterior portion without doing away with the pull of the muscles on the Achilles tendon

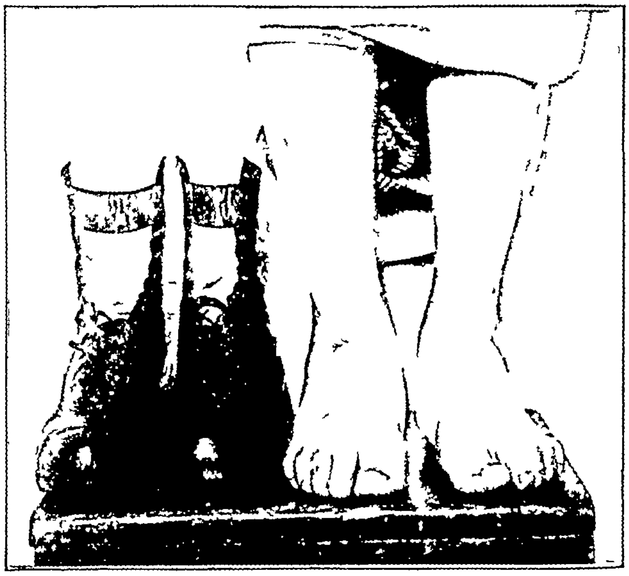

Fig 6 —Completed strapping of the feet with felt pad between adhesive and arches of the feet The adhesive plaster is started on the upper outer surface of the foot, and brought downward and inward with the foot in strong inversion, bringing the plaster upward and outward on the outer surface of the legs

Transportation of Milk—The milk ordinance of the city of Chicago, adopted in 1912, contained certain regulations with reference to the pasteurization of milk which were upheld by the state supreme court Provisions of this ordinance required that the milk should be transported in sealed cans and prohibited bringing milk into the city the temperature of which was above 55 F In a suit brought against a railroad company violating this provision with reference to temperature the state supreme court decided that unless it could be shown it was possible for a railroad company to ascertain the temperature of the milk without having access to the interior of the cans, the ordinance was unreasonable and not enforceable The court held however that a city has the right to protect the health of its citizens by reasonable regulations governing the transportation and sale of milk The decision in full is printed in *Public Health Reports,* January 19

FURTHER OBSERVATIONS ON THE USE OF THORIUM IN PYELOGRAPHY*

J EDWARD BURNS M D
Resident Urologist James Buchanan Brady Urological Institute the Johns Hopkins Hospital
BALTIMORE

Since the publication of the preliminary report[1] on the use of thorium solution as a pyelographic agent, many experimental investigations as to its pharmacologic action, and much clinical evidence after a year's experience in its use have led to the conclusion that it fulfils all the conditions requisite for an ideal pyelographic medium These conditions are that the solution be nontoxic (within the ordinary limits of usage) nonirritating, opaque to the Roentgen ray, giving not only a good shadow but one of clear delineation, possess a marked degree of fluidity, and be inexpensive

It is a well-known fact that the degree of opacity of an element to the Roentgen ray is directly proportional to its atomic weight On this account, thorium, being next to the heaviest known element, seemed worthy of careful study After an exhaustive investigation of its different salts and the various combinations into which they may enter, it was decided that the original solution, prepared in the manner suggested, and containing, as it does the double citrate of thorium and sodium together with an excess of sodium citrate, and some sodium nitrate was by far the best combination for use in pyelography The solutions used contain 10 and 15 per cent of thorium in the form noted, the 10 per cent solution being used for cystograms, and the 15 per cent for ureteropyelograms The 15 per cent solution contains approximately 15 per cent of thorium nitrate, about 9 per cent of sodium nitrate, and 21 per cent of sodium citrate, the thorium being probably in the form of a double citrate of thorium and sodium, and not occurring as the nitrate

Although solutions of thorium nitrate and thorium chlorid alone cannot be used clinically on account of their astringent and irritant action, and also the fact that they precipitate insoluble salts when brought in contact with the urine, they can be used to great advantage for outlining fine vessels and ducts in pathologic specimens These specimens, after being injected with a rather concentrated solution of the chlorid or nitrate, are fixed in Kaiserling's solution, which causes a precipitation of the insoluble salts of thorium in the walls of the vessels and ducts causing them to stand out with unusual clearness of delineation when a roentgenogram is made of the specimen so prepared

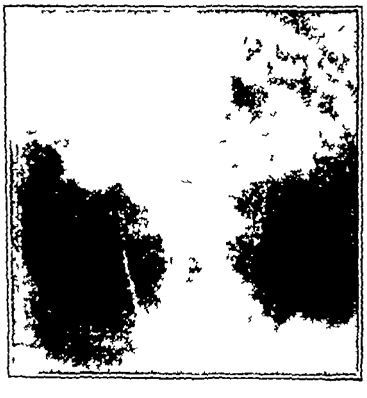

Fig 1 —Double pyelogram showing the same type of renal pelvis on each side The pelves are rather small and the calices greatly elongated

Since the thorium solution for clinical use contains a mixture of different salts, it was thought that a withdrawal of all of these excepting the double citrate of thorium and sodium (this salt being alone responsible for the shadow-casting properties) would be a great step toward simplification The substitution of other salts, namely, the chlorid for the nitrate of thorium, in the preparation of the solution, was also tried It was found, however that either the solution of the double citrate alone or any modification of the original solution when used experimentally, caused either an increase in toxicity, or the production of symptoms which were not observed when the original solution was used[2]

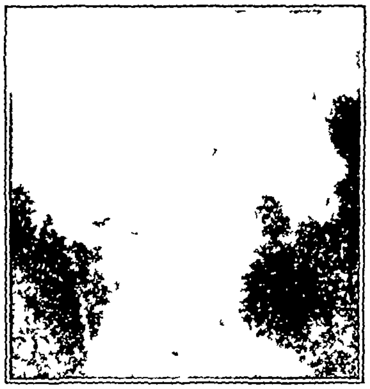

Fig 2 —Double pyelogram bilateral congenitally enlarged pelves

The use of this solution in the urologic clinic of this hospital was begun one year ago During this time it has been used in 185 cases, no untoward effects whatever having been observed In five of the cases where it was injected into the renal pelvis and ureter there was a slight reaction characterized by a slight rise in temperature, nausea and vomiting, all of which promptly subsided In one of these cases, on account of the marked irritability of the bladder, the patient had to be anesthetized before ureteral catheterization could be attempted, the etherization here could account for the symptoms produced At any rate, these same symptoms could be accounted for by ureteral catheterization alone, for they occur fully as frequently in cases where no solution is introduced into the renal pelvis and ureter In the series of cystograms there was nausea and vomiting in one case, and slight nausea and frequency of urination in another In the former instance the nausea and vomiting occurred some hours after the cystogram had been made, and may have been due to some dietary indiscretion In the latter instance, the patient was highly neurotic, which could readily account for the symptoms As much as 600 c c of the 10 per cent solution have been used in the entire urinary tract at one time This patient, a boy 12 years of age, had a dilated and trabeculated bladder with dilatation of the internal vesical sphincter, double hydro-ureters, and hydronephroses due to a congenital obstruction in the posterior urethra These conditions were all clearly demonstrated in the roentgenogram of this case No change in phenolsulphonephthalein output or blood urea content after the introduction of this solution into the urinary tract was demonstrated in this case, nor has there been any interference with kidney function, as shown by these two methods of investigation, in any of the cases in which it has been used, even though in some of these cases there had been a marked reduction in phenolsulphonephthalein output, and an increase in the blood urea content before the injection was made For pyelograms from 5 to 150 c c of the

[1] Burns J E Thorium—A New Agent for Pyelography Preliminary Report The Journal A M A June 26 1915 p 2126

[2] Burns J E Thorium—A New Agent for Pyelography Bull Johns Hopkins Hosp 1916 27, 157

15 per cent solution have been used, and for cystograms almost a liter (quart) of the 10 per cent solution

Too much emphasis cannot be laid on the method of introduction of the solution into the renal pelvis and ureter The gravity method is now recognized by urologists as being the most successful and the least dangerous for complete distention of the renal pelvis This is accomplished by means of a buret with a rubber tubing connection and a properly fitting nozzle for the end of the ureteral catheter, the buret being held slightly above the level of the patient, and the solution being allowed to flow in until the patient complains of a sensation of fulness in either kidney region The exposure to the Roentgen ray is then made, the solution being allowed to flow into the renal pelvis during the exposure Injection by means of a syringe is dangerous because there is always a liability to overdistention of the pelvis, and forcing the solution into the renal parenchyma or into the perirenal tissues

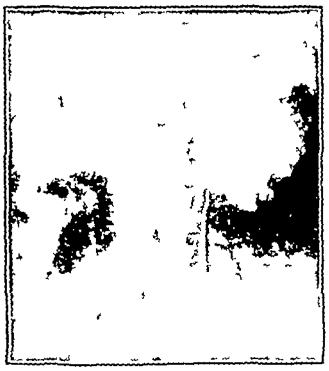

Fig 3 —Double pyelogram slight hydronephrosis on either side with marked irregularity of the outlines of the calices

A word may be said here in regard to the making of pyelograms in cases where there is a marked impairment of kidney function In these cases where the phenolsulphonephthalein output for two hours is only a trace, and the blood urea content well above normal, it may be well to avoid injecting both renal pelves at the same time In such cases the simultaneous injection of both renal pelves with any solution might sufficiently derange the functional activity of the renal epithelium, which is already markedly impaired, to cause the onset of uremia For this reason, it might be well to make a pyelogram on one side, and then wait a few days before making the other Again, where large hydronephroses and greatly dilated ureters are suspected, it may be well to allow the ureteral catheters to remain in position sufficiently long to insure a complete removal of the solution, for, as is well known, the peristaltic activity of a greatly dilated ureter is always markedly impaired, and consequently the elimination of the solution would be greatly prolonged

In pyelograms and cystograms made with this solution the outline of the renal pelvis and ureter, or the bladder, as the case may be, is not only remarkably definite but the shadow itself, even to its finest details, possesses an unusual clearness of delineation

The accentuation of the shadows of calculi by this solution, when they are not seen in the plain roentgenogram, is brought about either by the adhesive properties of the solution, by its capability of being absorbed, or by means of its comparative density For instance, in one case lately, the shadow of a ureteral calculus was brought out on one side where it was not seen in the plain roentgenogram, and on the other side, a renal calculus, which had previously been seen in the plain roentgenogram, was accentuated by the fact that its shadow was less dense than the shadow of the thorium solution surrounding it in the renal pelvis

The solution is clear and watery, and possesses such a marked degree of fluidity that it readily escapes from the renal pelvis, ureter and bladder This is shown by the fact that a plate made a few minutes after the injection has been discontinued gives no suggestion of a shadow, and assures its complete elimination from the urinary tract

The solution is not irritating to the mucous membranes of the renal pelvis, ureters and bladder This is demonstrated by the fact that no urinary symptoms have been observed in the cases in which it has been used No inflammation of the vesical mucous membrane has been observed at subsequent cystoscopic examination In cases which have come to operation within a few hours or days after the injection, examination of the bladder, ureters and renal pelvis has shown no evidence whatsoever of any irritative action Experimentally there has been no sign of any irritative action to the peritoneum in animals into whose peritoneal cavities this solution has been introduced, and all of the fluid has been absorbed in most instances In the preparation of the solution too much emphasis cannot be laid on its careful neutralization, and it is felt that this fact alone is responsible for the absence of any irritative action

The solution must be sterilized and kept sterile while being used, because, although it exhibits an inhibitory action on the growth of the ordinary bacteria, it is not bactericidal, and molds grow in it on standing It has been found that sterilization and resterilization of the same solution do not affect its stability in the least

As regards its use in bladder and kidney injections, no evidence of toxicity has been observed Experimentally this solution is far less toxic than collargol In animals where it has been given in small doses subcutaneously, intramuscularly, intraperitoneally and intravenously there has been no effect Larger doses have occasionally produced gastro-intestinal symptoms, while very large doses have in some instances produced death These fatal doses, of course, were far above the ordinary limits of clinical usage In a few instances 2 c c of this 15 per cent solution per kilogram (intraperitoneally and intramuscularly) proved fatal, much larger doses being required intravenously to produce death This, in the case of an ordinary man of 70 kg, would allow the escape of 140 c c of the solution into his tissues before evidence of toxicity—ten times as much as is used in a simple pyelogram, and hundreds of times greater than any small amount that might be absorbed during the procedure Much larger amounts have been used in the renal pelvis without any ill effects

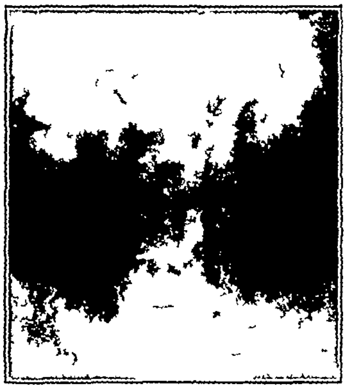

Fig 4 —Double pyelogram showing well marked bilateral hydronephroses and hydro ureters with kinking of the right ureter due to narrowing of the ureterovesical orifice

CONCLUSIONS

1 *Thorium solution fulfils all the conditions necessary for an ideal pyelographic medium*

2 Clinically there has never been the slightest evidence of toxicity in a series of 185 cases, the amounts used in a single case varying from a few cubic centimeters to a liter This alone is proof of its nontoxicity

3 Experimentally, although in a few instances death has followed the injection of large doses into the peritoneal cavity and tissues of animals, larger doses intraperitoneally and intravenously have produced no effect

4 That the solution is nonirritating is shown by the absence of any urinary symptoms after its use and the absolute lack of any such evidence cystoscopically, and at operation

5 The pyelograms and cystograms made with this solution show a splendid shadow which possesses an unusual clearness of delineation

6 The solution is clear and watery, therefore it possesses a great degree of fluidity, permitting its ready elimination from the urinary tract

7 It is perfectly clean and does not stain the linen In this particular it possesses another marked advantage over other solutions, particularly those of the silver salts

8 It is quite inexpensive, being about one third as costly as collargol

ABSTRACT OF DISCUSSION

Dr John T Geraghty, Baltimore Pyelography has become almost indispensable In certain cases it is practically the only means we have of arriving at an accurate diagnosis For that reason it is very necessary that we have a substance which is comparatively free from danger, and I think Dr Burns has given us such a substance I do not think you will ever be able to introduce into the kidney a foreign substance in cases that should not have pyelography, I think you would endanger the kidney by injecting salt solution under force The mere catheterization in some cases may be sufficient to induce uremia, particularly in cases with marked reduction in function, and if bilateral So that it is essential in very bad kidneys to have a substance not irritating and that will not reduce the function I do not believe that thorium will injure the kidney any more than salt solution will

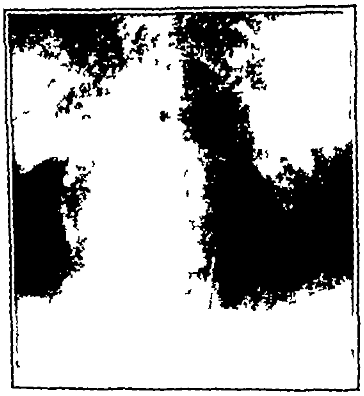

Fig 5—Double pyelogram showing double renal pelvis and double ureter on the right side with a calculus in the upper pelvis Moderate grade of hydronephrosis on the left side due to stone in the lower end of the left ureter

Dr William F Braasch, Rochester, Minn The value of pyelography is well understood now and generally recognized It is unfortunate that a year or two ago so many accidents were reported with its use It was in danger of falling into disuse By means of thorium, however, it is very probable that pyelography will come into its own Several years ago I said that that medium which was in thorough solution and which was nonirritating would be the best Colloidal silver solutions are not solutions, they are suspensions Some are more or less irritating, and therefore we had two important objections to pyelography The ill results following pyelography were the results of two distinct errors of technic—overdistention, and permitting the fluids to remain in the distended pelvis where they could not drain out again Thorium is a medium in solution, and which, even if injected into a distended pelvis and retained, will, as a rule, not cause any trouble I have seen four or five cases in which thorium was injected into large hydronephrotic sacs and cortical necrosis resulted I do not know whether it was due to the thorium alone or to a secondary infection that happened at the time of the injection of the thorium I am under the impression it was the latter but we should not jump to the conclusion because thorium has so many advantages over colloidal silver I still maintain that pyelography should not be done when we can make a diagnosis without it One objection to thorium is the fact that it does not give as good an outline of the ureter as do the colloidal silver salts Great care is required in the preparation of thorium and the ordinary chemist or druggist is not competent to do it The uniformity of clear cut delineation is not present as frequently as with collargol When there is no danger of retention and I wish to get a clear outline of the calices I still employ a 15 per cent collargol solution

Dr O S Lowsley, New York I want to add a word of warning in regard to the use of thorium In one of the clinics I am connected with we have been using thorium in all cases of pyelography We have never had any bad effects, but one of my confreres reported a case in which he had used thorium by gravity and gravity distention of the kidney pelvis, and when the first cessation of the flow appeared, or the patient complained of pain, a small amount of the solution was allowed to flow back before the picture was taken My confrere used thorium according to Dr Burns' method After the patient had passed a lot of black, tarry-looking, bloody material, she went into shock and died I am not exactly familiar with the history of the case She may have been one of the patients who should not have been pyelographed at all, but death apparently resulted from thorium

Dr E O Smith, Cincinnati Some years ago I reported a death from pyelography The patient was an aged lady who had a number of pathologic conditions, and perhaps this particular examination should not have been undertaken The patient died within five minutes after the pelvis of the kidney was dilated with slight gravity pressure and the picture taken She did not die from toxicity, but from shock All of us have seen cases and had experiences where there was pronounced shock following this method of examination Another case that came to me was a particularly sad experience It was that of a physician, a man past 60 years of age, who had a tumor mass in his left side We were unable to find anything abnormal in his urine, using the ordinary tests As a matter of differentiation to determine whether or not the mass was in the kidney pyelography was done The left kidney pelvis was injected under gravity with 10 per cent collargol This man suffered excruciating pain shortly afterward We went to his home 40 miles in the country the following day He passed absolutely no urine after we injected the pelvis of the kidney He died about five days afterward from anuria This emphasizes the point we ought to bear in mind that a distention of one kidney or some irritation produced in the kidney by this method of examination may have its effect on the other kidney, and this patient evidently had that effect, because the other kidney was catheterized at the time and there was nothing wrong with its function Having these experiences in mind, I am like Dr Braasch and take the position that this method of examination should not be employed until all other methods have been tried We use it as a last resort

Dr J Edward Burns, Baltimore There are certain borderline cases in which pyelography should not be employed In those cases in which the functional activity of the kidney is markedly impaired, for instance, those in which only a trace of phenolsulphonephthalein is excreted in two hours and the blood urea content is above normal on preliminary examination, a double pyelogram should be made with the greatest care It would be better to make a pyelogram of one side and then wait a few days before making one of the other side, because the activity of the renal epithelium is in a state of unstable equilibrium so to speak, just on the borderline, and the balance can readily be upset by the introduction of any solution In regard to the introduction of the solution it has been brought out in the discussion and has been known for some time, that the least harmful and the most successful procedure for insuring complete distention of the renal pelvis is the gravity method, and as I stated previously, in our record of 185 cases in which this thorium solution has been used by this method we have had absolutely no trouble whatever In cases where hydro-ureter and hydronephrosis are suspected it is well to leave the ureteral catheter in place for a while, so as to insure the drainage of as much of the solution from the pelvis and ureter as possible, because the peristaltic activity of the ureter is greatly impaired in these cases and for that reason their emptying is greatly prolonged In borderline cases where there is marked impairment of function and pyelography is done, I do not feel that any harmful results could be attributed to the solution used for it is largely due to the fact that the patient is in such a state that the functional equilibrium of the kidneys can be upset easily and by anything Dr Lowsley did not state as to whether the case he reported had been worked out from a functional standpoint or not previous to the injection of the renal pelves so it would be pretty hard in a case like that to say definitely whether the solution had anything to do with the death of the patient or not It is always well to have the renal function worked out definitely before pyelography is undertaken We have had absolutely no trouble whatsoever at the Brady Urological Institute in the use of this solution

THE TRANSPLANTATION OF FAT IN PROSTATIC AND KIDNEY SURGERY *

IRVIN S KOLL BS, MD
Professor of Genito Urinary Surgery Post Graduate Medical School and Hospital, Associate Genito Urinary Surgeon Michael Reese Hospital
CHICAGO

In the desire to utilize some means less mechanical than the various procedures suggested for the prevention of postoperative hemorrhage in suprapubic prostatectomy, nephrotomy and pyelotomy, this work was undertaken

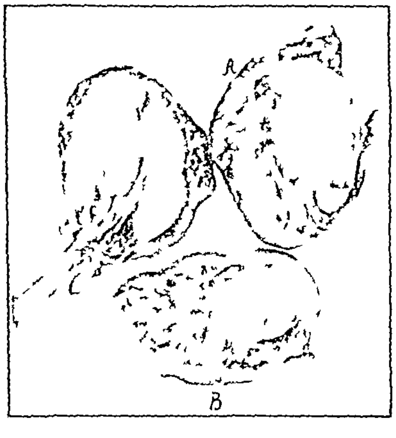

Fig 1 —Kidney lacerated in several places Fat sutured into wound Ten days after operation

The use of fat in surgery dates back to 1893, when Neuber suggested its use in lacerations of the liver His work was followed by Lexer and Czerny, and later by Klopfer in bone surgery I have been unable to find any reference made to the use of fat in kidney or prostatic surgery, except that of a preliminary report by Dr Kolischer,[1] which appeared two years ago

The experiments were carried out on dogs The kidneys were traumatized by crushing and lacerating and nephrotomized in various ways, also decapsulated, and fat from either the same animal or previously obtained from another dog sutured or tied into or over the wounds Some of the transplants were infected with colon bacilli and some with staphylococci

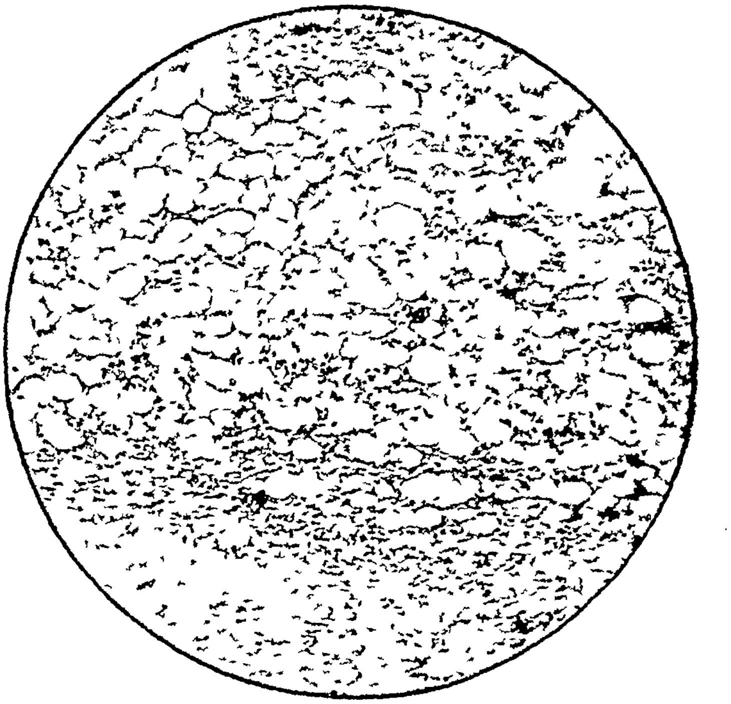

Fig 2 —Section taken from *A* showing progressive metamorphosis of the fat replacing the capsule which was peeled off Ten days after operation

It was in every instance very striking to see how promptly the bleeding stopped The kidneys were removed at periods following the operation varying from one day to six months

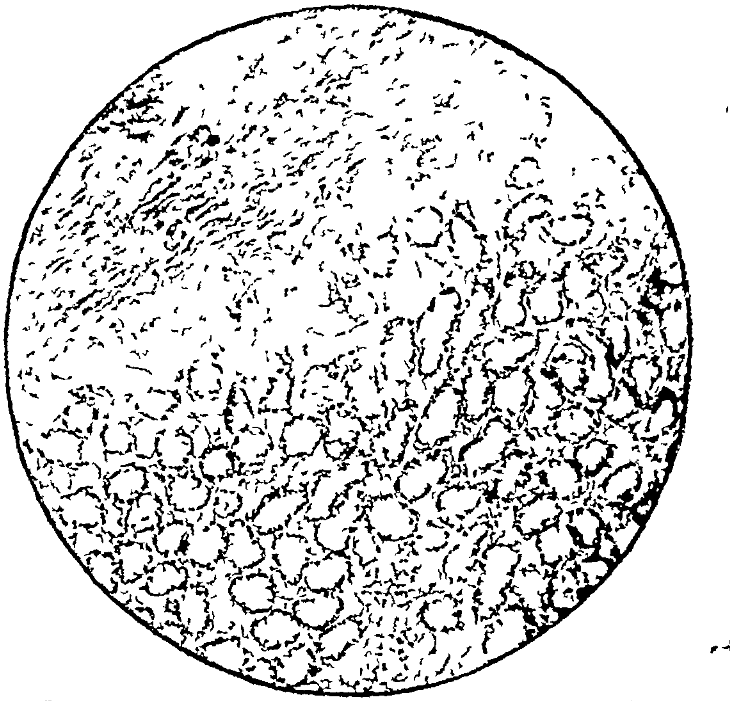

Fig 3 —Deep nephrotomy Fresh fat sutured in wound Four weeks after operation

On account of the anatomy of the prostate in the dog, the human prostatectomy could not be simulated By making pockets out of flaps of the bladder wall

[1] Kolischer Urol and Cutan Rev December 1914

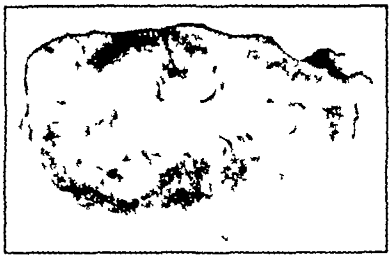

Fig 4—Deep incision into kidney Fat fixed in wound with three sutures Fourteen days after operation

it was possible to study the effect on fat transplanted into the bladder In each instance the fat rapidly disintegrated and completely disappeared from these formed pockets

Clinically, the experience has been more limited to the prostate The technic is simply to fill up the cavity made by the enucleation of the prostate and suture over the edges of the mucous membrane, leaving just enough of an opening for drainage and sloughing of the fat, which always takes place in two or three days, when it has served the purpose for which it was intended The fat can be taken from the abdominal incision of the patient, if he is sufficiently adipose or, better still, obtained from a dog previously Kept on ice in normal salt solution, in air-tight containers, the fat can be preserved indefinitely In almost every instance the oozing, as noted by the colored urine, will cease in twenty-four hours

This use of fat has also been tried in a number of nephrotomies for the removal of calculi from the parenchyma, and on several pyelotomies, also on one ruptured kidney by Dr Kolischer In the latter case the bleeding stopped immediately following the suturing of the fat over the rupture, and some months later was functionating without any hematuria

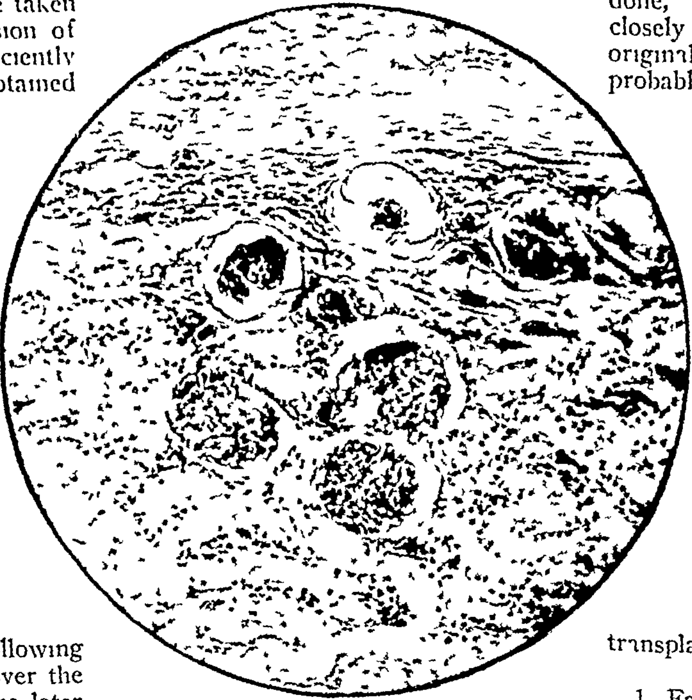

Fig 6—Kidney decapsulated, covered with fresh fat and then injected with staphylococci Sixty nine days after operation (Note New capsule of converted connective tissue Glomerulitis)

The study of sections taken from the areas in which the fat was transplanted shows a typical metaplasia of reticular connective tissue, becoming fibrous Grossly, in most instances where the traum was sufficiently extensive, secondary contraction reduces the kidney to one half or one quarter its normal size The process begins promptly, and in twenty-four hours the fibrin deposits show beginning organization The ultimate change is reached in three to four months in the absence of infection, and somewhat later in the presence of bacteria Infection, however, does not change the end-results at the site of the transplant, though the renal parenchyma remote from the transplant gives evidence of bacterial invasion

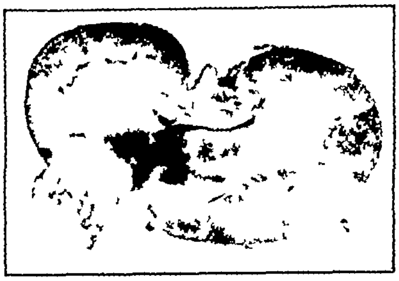

Fig 5—Scalpel plunged from cortex down to pelvis Wound then plugged with fat Twenty eight days after operation

A new capsule forms where decapsulation has been done, the structure of which closely resembles that of the original kidney capsule This probably explains why the Edebohls operation for the relief of chronic interstitial nephritis ultimately fails

In every specimen examined there is considerable necrosis of the renal tissue for some distance from the point of trauma This necrosis should suggest refraining from the unsurgical procedure of cutting into the kidney for the search of calculi The necrotic area is replaced by fibrous tissue, and in later months cannot be distinguished from the changed fatty transplant

SUMMARY

1 Fat is a valuable hemostatic following prostatectomy and in operations on the kidney

2 The change into fibrous connective tissue is complete in from three to four months

3 Infection does not alter the metaplasia, though it delays it

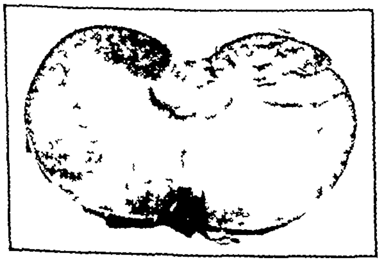

Fig 7—Deep nephrotomy Fresh fat sutured in wound Four weeks after operation

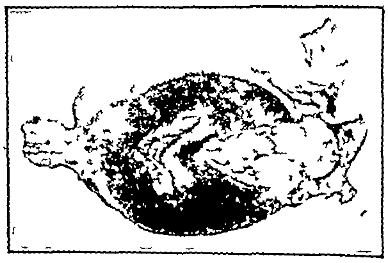

Fig 8—Nephrotomy filled with fat, one week old Thirty seven days after operation

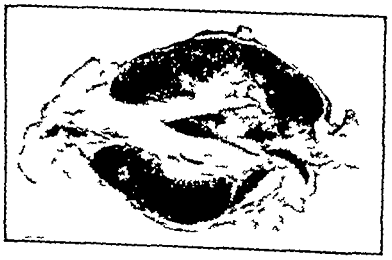

Fig 9—Deep nephrotomy, filled with fat and infected with twenty four hours colon bacillus culture Two and one half months after operation

procedure for insuring complete distention of the renal pelvis is the gravity method, and as I stated previously, in our record of 185 cases in which this thorium solution has been used by this method we have had absolutely no trouble whatever In cases where hydro-ureter and hydronephrosis are suspected it is well to leave the ureteral catheter in place for a while, so as to insure the drainage of as much of the solution from the pelvis and ureter as possible, because the peristaltic activity of the ureter is greatly impaired in these cases and for that reason their emptying is greatly prolonged In borderline cases where there is marked impairment of function and pyelography is done, I do not feel that any harmful results could be attributed to the solution used for it is largely due to the fact that the patient is in such a state that the functional equilibrium of the kidneys can be upset easily and by anything Dr Lowsley did not state as to whether the case he reported had been worked out from a functional standpoint or not previous to the injection of the renal pelves so it would be pretty hard in a case like that to say definitely whether the solution had anything to do with the death of the patient or not It is always well to have the renal function worked out definitely before pyelography is undertaken We have had absolutely no trouble whatsoever at the Brady Urological Institute in the use of this solution

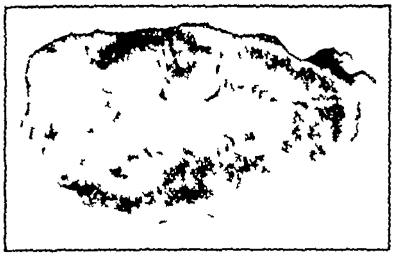

Fig 4—Deep incision into kidney Fat fixed in wound with three sutures Fourteen days after operation

it was possible to study the effect on fat transplanted into the bladder In each instance the fat rapidly disintegrated and completely disappeared from these formed pockets

Clinically, the experience has been more limited to the prostate The technic is simply to fill up the cavity made by the enucleation of the prostate and suture over the edges of the mucous membrane, leaving just enough of an opening for drainage and sloughing of the fat, which always takes place in two or three days, when it has served the purpose for which it was intended The fat can be taken from the abdominal incision of the patient, if he is sufficiently adipose or, better still, obtained from a dog previously Kept on ice in normal salt solution, in air-tight containers, the fat can be preserved indefinitely In almost every instance the oozing, as noted by the colored urine, will cease in twenty-four hours

This use of fat has also been tried in a number of nephrotomies for the removal of calculi from the parenchyma, and on several pyelotomies also on one ruptured kidney by Dr Kolischer In the latter case the bleeding stopped immediately following the suturing of the fat over the rupture, and some months later was functionating without any hematuria

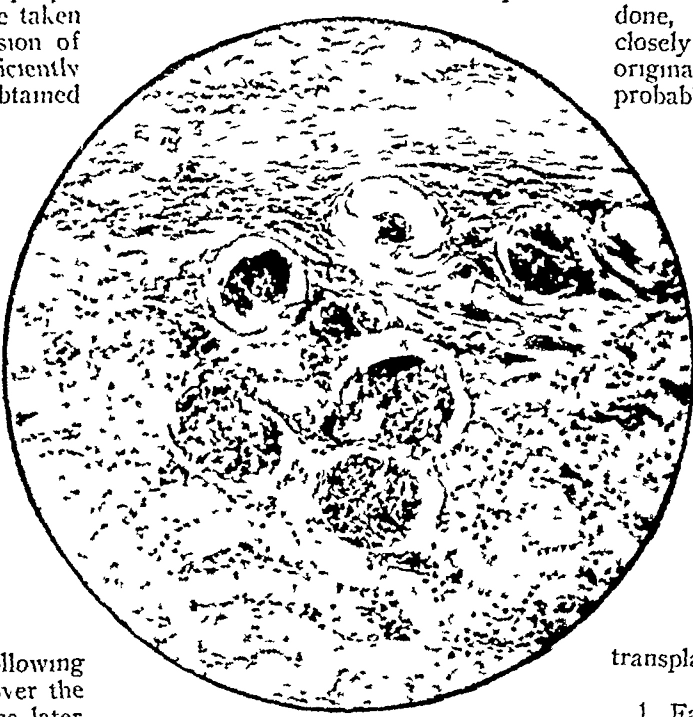

Fig 6—Kidney decapsulated covered with fresh fat and then injected with staphylococci Sixty nine days after operation (Note New capsule of converted connective tissue Glomerulitis)

The study of sections taken from the areas in which the fat was transplanted shows a typical metaplasia of reticular connective tissue, becoming fibrous Grossly, in most instances where the traum was sufficiently extensive, secondary contraction reduces the kidney to one half or one quarter its normal size The process begins promptly, and in twenty-four hours the fibrin deposits show beginning organization The ultimate change is reached in three to four months in the absence of infection, and somewhat later in the presence of bacteria Infection, however, does not change the end-results at the site of the transplant, though the renal parenchyma remote from the transplant gives evidence of bacterial invasion

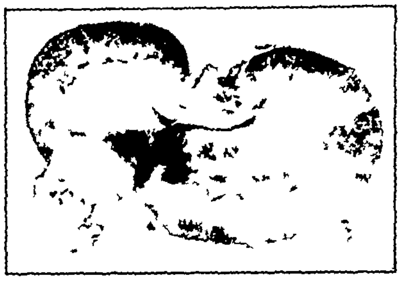

Fig 5—Scalpel plunged from cortex down to pelvis Wound then plugged with fat Twenty eight days after operation

A new capsule forms where decapsulation has been done, the structure of which closely resembles that of the original kidney capsule This probably explains why the Edebohls operation for the relief of chronic interstitial nephritis ultimately fails

In every specimen examined there is considerable necrosis of the renal tissue for some distance from the point of trauma This necrosis should suggest refraining from the unsurgical procedure of cutting into the kidney for the search of calculi The necrotic area is replaced by fibrous tissue, and in later months cannot be distinguished from the changed fatty transplant

SUMMARY

1 Fat is a valuable hemostatic following prostatectomy and in operations on the kidney

2 The change into fibrous connective tissue is complete in from three to four months

3 Infection does not alter the metaplasia, though it delays it

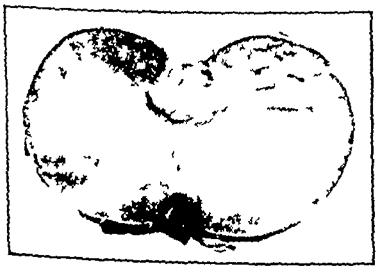

Fig 7—Deep nephrotomy Fresh fat sutured in wound Four weeks after operation

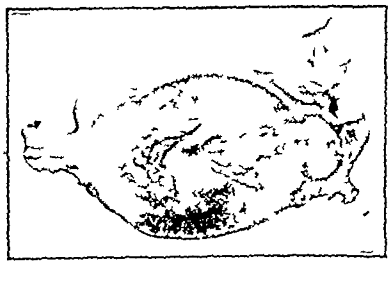

Fig 8—Nephrotomy filled with fat one week old Thirty seven days after operation

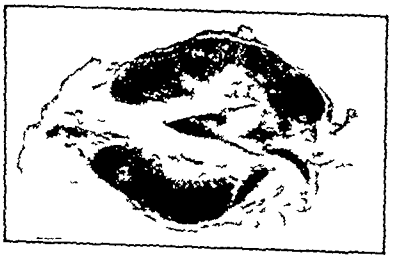

Fig 9—Deep nephrotomy filled with fat and infected with twenty four hours colon bacillus culture Two and one half months after operation

4 When placed over a decapsulated kidney, a new capsule is formed

5 Incision into healthy kidney is followed by extensive necrosis, which is replaced by fibrous tissue

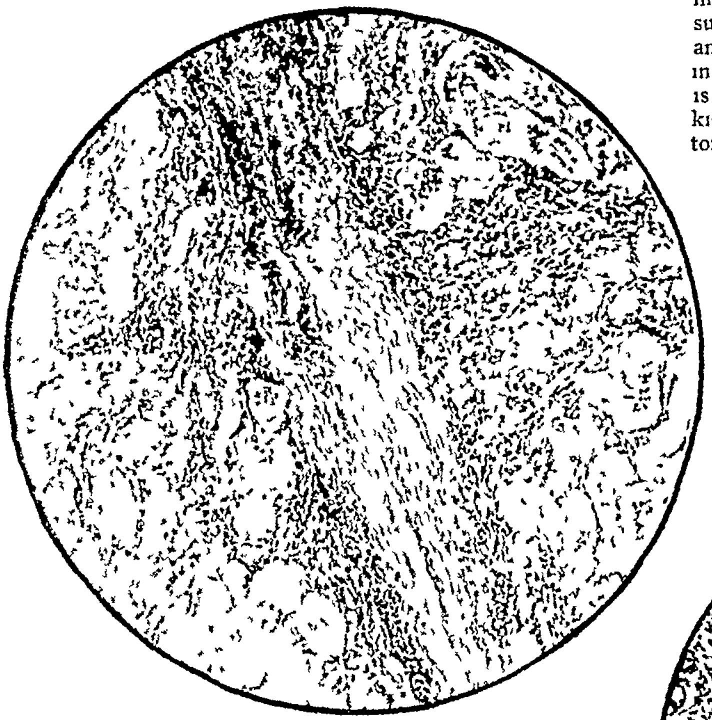

Fig 10—One deep nephrotomy at either pole, filled with human fat, one day old Seventy six days after operation Kidney was shrunken to one quarter its normal size (Note Change of fat into fibrous connective tissue Extensive change in tubules)

Contrary to the usual sequence, clinical experience preceded the laboratory work, and I am indebted to Dr G Kolischer for the inspiration leading to this work

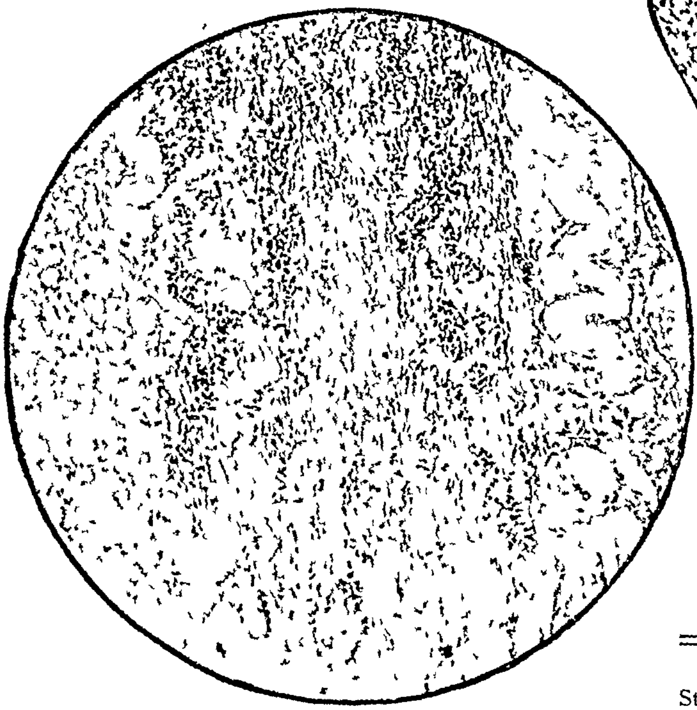

Fig 11—Nephrotomy filled with fat and injected with culture staphylococci Two months after operation

ABSTRACT OF DISCUSSION

Dr G Kolischer, Chicago I hope that these experiments will encourage you to use this transplantation of fat in renal and bladder surgery rather extensively For the efficiency of this method I have plenty of clinical evidence I want to mention three types of procedure The first is the reinforcement of the pelvis of the kidney after pyelotomy After the incision in the pelvis is sewed up we leave the ends of the sutures long, and then we pull up a flap of the peritoneal fat and tie it over the pelvis with the long ends of the suture, in that way the oozing stops immediately The second type is the padding of the kidney incision for a rupture in the kidney or after a nephrotomy The third type is in prostatectomy I am convinced that a great many of our prostatectomized patients used to die by simply oozing themselves to death through the bladder In order to prevent hemorrhage we place a piece of fat in the cavity, and anchor it with a few stitches

Dr H J Scherck, St Louis About a year ago Dr Kolischer suggested this method to me, and since that time I have had occasion to use fat in three cases of traumatized kidneys in a railroad hospital, and in all of the cases the result was entirely satisfactory I have used it a number of times in prostatic surgery where the bleeding seemed to be excessive, and found it entirely satisfactory

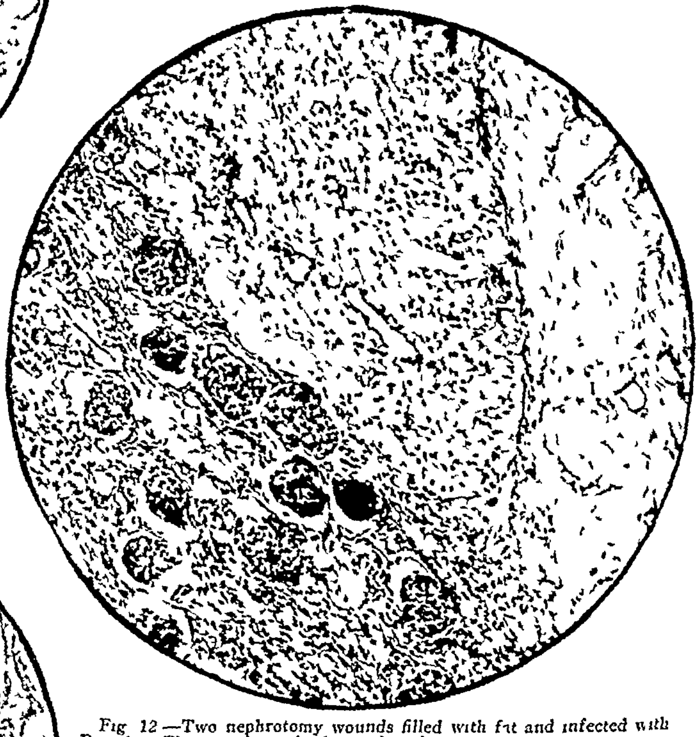

Fig 12—Two nephrotomy wounds filled with fat and infected with B coli Three and one half months after operation

Dr David W MacKenzie, New York I got the fat suggestion from Dr Charles Gibson of New York, who has tried it, I believe, in a number of kidney cases, sometimes without drainage I have always drained I have never used it in the prostate It seems very simple

Dr Irvin S Koll, Chicago I want to emphasize the fact that you need have no hesitancy in removing the fat from a dog Put it in air-tight containers on ice and it will keep indefinitely I think it is of advantage to do this, because where you remove it from the abdominal wall in a prostatectomy it delays the operation, leaves an open space, and it takes time to ligate the bleeding vessels

Spotted Fever—According to the annual report of the Idaho State Board of Health, Rocky Mountain spotted or tick fever decreased one half during 1916 as compared with the previous year In 1915 there were 349 cases, resulting in fourteen deaths In 1916 there were only 148 cases, eleven resulting in death The disease has been studied since 1910 by the state and federal authorities, and the reduction in the number of cases is attributed to these investigations

MIGRATION OF SHELL FRAGMENT FROM RIGHT FEMORAL VEIN TO RIGHT VENTRICLE OF HEART

GENERALIZED GAS BACILLUS INFECTION *

HENRY H M LYLE, M D
Professor of Clinical Surgery, Columbia University, College of Physicians and Surgeons, Attending Surgeon, St Luke's Hospital
Late Chirurgien Chef, Ambulance d' Annel, Oise, France
NEW YORK

History —The patient, F A, Eighth Zouaves, was brought, June 16, at 3 30 a m, to the ambulance Four hours previously he had received a perforating shell wound of the left thigh 4 cm above the knee, and a penetrating shell wound of the right thigh A fluoroscopic examination of the thigh and lower abdomen failed to reveal any foreign body Unfortunately the upper abdomen and thorax were not examined The failure to find the shell fragment was puzzling, as the depth and direction of the wound seemed to preclude the possibility of the particle having fallen out

The patient was in a condition of mild shock The temperature was 97.2, pulse 126 respiration 28 Physical examination of the chest and abdomen was negative

Operation —The contused skin edges were cut away, the wound laid open, and the projectile tract lightly but methodically excised No foreign bodies were discovered At the bottom of the wound of the right thigh, the femoral vessels were found embedded in a clot, the femoral vein was bruised but apparently intact Two Carrel instillation tubes were inserted, and 20 c c of Dakin's hypochlorite solution were delivered to the wound every two hours

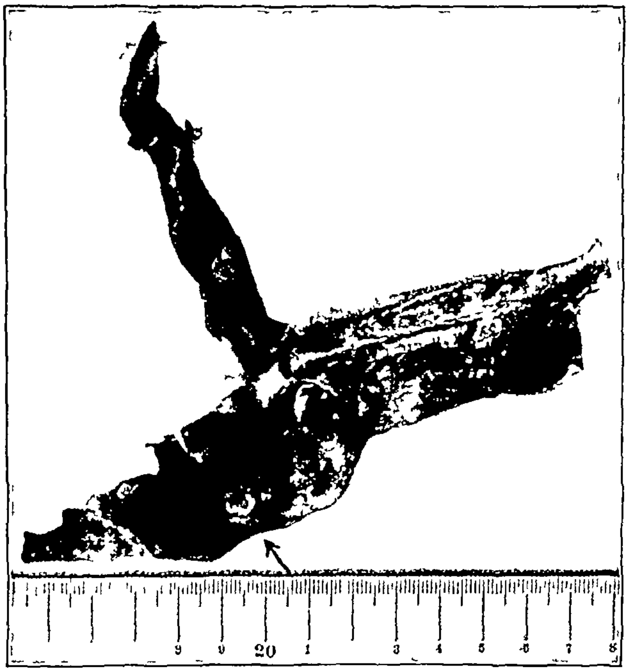

Fig 1 —Femoral vein and artery showing the wound in the femoral vein

The patient appeared drowsy and slept the major portion of the first two days On the third day the abdomen became greatly distended, and he complained of pain and tenderness over the spleen and right kidney The distention was partially relieved by lavage and enemas Jaundice appeared on the morning of the fourth day, and was accompanied by pain and tenderness over the liver The temperature rose to 102 2, the pulse to 132, and the respiration to 32 Fine moist rales were heard at the left base The area of cardiac dulness had increased, a distinct pericardial rub was heard, and the cardiac sounds were indistinct A provisional diagnosis of general gas bacillus infection with pericarditis and pneumonia was made In the afternoon there was a temporary improvement, followed by sudden death at 5 30 Throughout the course the wound remained sterile

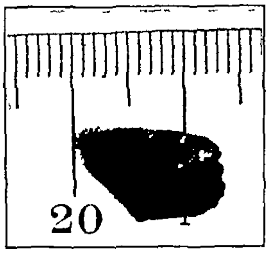

Fig 2 —The shell fragment carried by the blood stream from the right femoral vein to the right ventricle

Necropsy (Dr Proctor) —The body is that of a man, aged 31, medium frame, fairly well nourished The skin is deeply jaundiced There are no wounds of the abdomen or thorax The wounds of the thigh are clean The wound of the right thigh is 10 cm below and 5 cm posterior to the anterior superior spine of the ilium The tract leads forward, downward and inward to the femoral vein (Fig 1) In the external wall to the vein there is a small valve-like wound sealed by an organized clot There is no local evidence of gas infection Both lungs are edematous, there is a fibropurulent pericarditis with free gas in the pericardial cavity The heart is enlarged, and its external surface is covered with a fibropurulent exudate The cut section of the heart gives a gaseous crepitation There is a rough shell fragment free in the cavity of the right ventricle (Fig 2) The shell fragment measures 1 5 cm in length, 0 9 cm in width, and 0 5 cm in thickness, and weighs 1 81 gm There are fibers of clothing adherent to the irregular surface of the shell The liver, spleen and kidneys are enlarged On cut section all give gaseous crepitation There is no obstruction to the gallbladder or gallducts

Revised Diagnosis —Perforating wound of the left thigh, penetrating wound of the right femoral vein, migration of the shell fragment to the right ventricle of the heart General gas bacillus infection No local infection of the wound

Besides the extreme rarity of the case, the following points are worthy of notice

1 The carrying of a rough shell fragment by the blood stream from the right femoral vein to the right ventricle, the patient living four days and eighteen hours

2 The sealing up of the wound in the vein

3 The sterilization of the local wounds by the Carrel method, the generalized gas infection having undoubtedly arisen from the clothes on the shell fragment

A fluoroscopic examination of the upper abdomen might have revealed the presence of the shell fragment It then would have been a simple matter to milk the fragment into an unimportant vein from where it could have been easily removed This has already been done in the case of a shrapnel ball [1]

50 East Fifty-Third Street

* The heart shell fragment and vein were shown before the Surgical section of the New York Academy of Medicine Oct. 6 1916

End-Result Investigation —The investigation of surgical end-results is a matter of serious importance The employment of special workers to carry on end-result investigations in the field is now the practice of a number of hospitals Despite the cost involved such proposals should be sympathetically received by hospital administrators The hospital is one of the greatest of existing social institutions, supported in this country at a total cost which staggers the imagination The value of its output must not be assumed, but must be proved The altruistic hospital surgeon will not permit his equanimity to be disturbed by the revelations of end-result investigations, if the disclosures are sometimes surprising they are always instructive —S S Goldwater M D *Modern Hospital* November, 1916

LYMPHOGENOUS ASCENDING INFECTION OF THE URINARY TRACT *

DANIEL N EISENDRATH, A B, M D
AND
OSCAR T SCHULTZ, A B, M D
CHICAGO

In an earlier communication[1] we reported the results of a series of experiments which showed that infection of the upper urinary tract can take place when an emulsion of organisms is injected into the bladders of rabbits and dogs Our studies in this first series enabled us to conclude that the paths along which the infection travels are the lymphatics of the wall of the ureter and of the renal pelvis The view that infection reaches the kidney from the bladder by way of the lumen of the ureter must, we feel, be abandoned, except for those cases in which an almost complete obstruction exists

In our first paper we reviewed the work of earlier investigators, which was performed under conditions seldom met with in the human being In the majority of experiments cultures were injected into the ligated ureter Under these conditions it was not surprising to find organisms within seven hours in the tubules of the kidney[2]

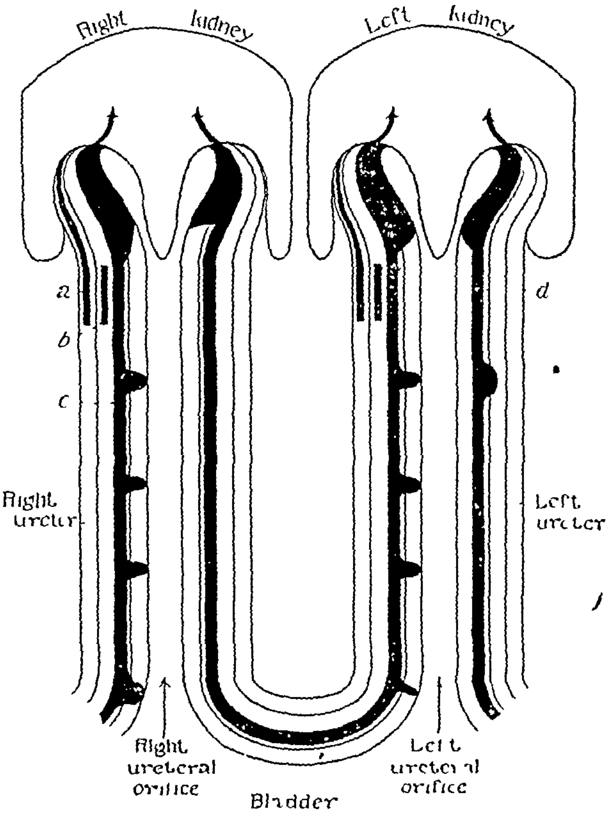

Fig 1—Diagram of Experiment 423 Shaded areas indicate paths of infection as indicated by inflammatory infiltration which could be followed from the bladder to the kidney *c* submucous infiltration with occasional extension into the mucosa *b* and *a* infiltration in muscular and periureteral coats *d* submucous infiltration in left ureter extending at one level into the muscular coat

Other investigators, like Sweet[3] and Sweet and Stewart,[4] implanted the cut ends of the ureters into the intestine They called attention to the same perivascular areas of infiltration as we have found and to the probability that the infection travels by way of the interstitial lymphatics of the ureter Their method is open to criticism because the changes which take place after reimplantation of the ureter into the intestine are so intense and occur so early that it is impossible to follow the paths of infection It also opens up the lymphatics in a manner practically never met with in our clinical cases Hess[5] injected cultures into the bladder and found no changes after intravesical inoculation alone, but these results may have been due to the small amount injected and the long interval which elapsed between the time of the experiment and the time microscopic examination was made Our technic was the same in both series of experiments. The organisms employed were *Bacillus coli, Staphylococcus aureus* and *Bacillus proteus*

An emulsion of sterile salt solution and scrapings of four agar slant cultures of the organisms was injected through a silver cannula into the bladders of female animals[6] Before this intravesical inoculation some of the urine was obtained for cultures, so as to determine the presence of any preexisting infection The cultures taken from the urine before the experiments were sterile in all of the animals of both series Every precaution was taken to avoid injury to the urethra and bladder, and a minimal degree of force was used in injecting the emulsion By following this method we imitated the conditions existing clinically as closely as possible There was absolutely no interference with the sphincteric action present at the vesical end of the ureter, our idea being to permit the organisms to invade the bladder mucosa and be carried into the intramural and periureteral lymphatics of the ureter through the anastomosis of the lymphatics of the bladder and ureter, previously discovered by Stahr,[7] and Bauereisen,[8] referred to in our first communication[1]

Our animals were killed at varying intervals with strychnin, and cultures were immediately made from the heart's blood, both kidneys, and from the bladder Serial sections of the entire ureter and renal pelvis were made in order to follow the paths of infection from one level to the next higher in longitudinal sections Portions of the bladder at some distance from the vesical end of the ureter and areas from every portion of the kidney were also examined in serial sections

We employed only dogs in our second series because of the presence of slight inflammatory changes in the rabbit controls of the first series All of the blood cultures of the second series were negative The organism injected was found at necropsy in the bladder of two animals, but never in the kidneys, out of a total of thirteen experiments

The ureter and renal pelvis showed evidence of involvement of varying grade in every dog In three of the animals, one inoculated with *B coli* and two with *B proteus,* the kidney was also involved

We believe that our method of injecting the organisms reproduces as closely as possible the conditions found clinically in infections of the lower urinary tract The negative cultures of the urine obtained before injection prove the absence of any previous infection The negative blood cultures in twenty-six animals of the first series and in thirteen of the second series eliminates the possibility of a hematogenous infection

The details of the experiments will be published elsewhere, but the summarized microscopic findings in two typical experiments are given herewith In Experiment 423 an emulsion of *B coli* was injected into the bladder and the dog was killed five days later In this animal the inflammatory infiltration, as shown in Figure 1, follows the lymphatics of the submucous coat from the bladder into the ureter Near the upper ends of the two ureters the outer coats become markedly involved and the renal pelvis is the seat of an intense, subacute, inflammatory reaction From the pelvis the infiltration can be followed into the parenchyma of the kidney along the course of the intrarenal lymphatics The lining epithelium of the ureter and of the renal pelvis is intact, except where it has become secondarily invaded by inflammatory foci which had their origin in the subjacent coat (Fig 1)

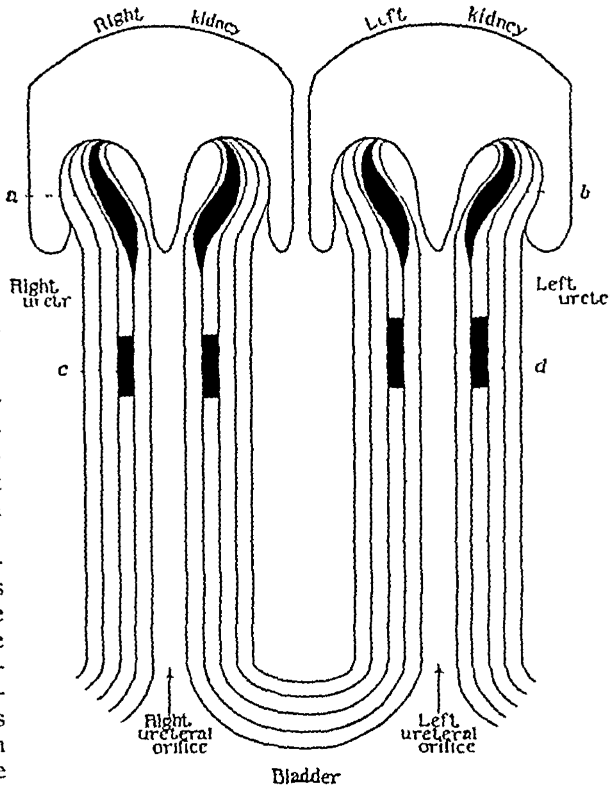

Fig 2 —Diagram of Experiment 431 Shaded areas indicate regions of infiltration in submucous and mucous coat of right (*a*) and left (*b*) renal pelves the infiltration in the submucous coat of the ureters is shown at *c* and *d*

Throughout the urinary tract the inflammatory process is characterized by focal lymphoid infiltration about smaller blood vessels and lymphatics In Experiment 431, a dog killed five days after injection of *B proteus* into the bladder, the involvement is somewhat different in that it is most marked in the upper portion of the urinary tract (Fig 2) In the renal pelvis the inflammatory reaction becomes quite intense and from the pelvis extends up into the medullary tissue of the kidney in the form of intertubular perivascular bands of lymphoid infiltration In the ureters of this animal the only change of any importance to which we would call attention is swelling and proliferation of the endothelium of the lymphatics, about some of which there is a very narrow zone of lymphoid infiltration

Seven uninoculated dogs were examined as controls, the examination in each case being based on serial sections of the entire urinary tract from the bladder to the kidney All were negative with one exception, in which the ureter and renal pelvis showed slight foci of perivascular infiltration, similar to those found in animals killed at longer periods after inoculation This finding in one control dog does not invalidate our experiments, but rather strengthens them and indicates that dogs are susceptible under natural conditions to ascending infections of the urinary tract by way of the interstitial lymphatics of the ureter

The microscopic findings in our second series agree in every respect with those of the first series of experiments The most marked reaction occurs after *B coli* and the least after *Staphylococcus aureus*, while after *B proteus* there is a reaction intermediate between the other two Common to all of the experiments was the intact condition of the lining epithelium of the urinary tract The inflammatory changes followed the course of the lymphatics from the bladder to the ureter and from this in turn to the renal pelvis and kidney in such a large number of experiments that we believe there can no longer be any doubt about the paths in ascending infections of the urinary tract

A glance at Figure 3 will impress one with the importance of the clinical application of our experimental work Organisms can be carried to the kidney from the bladder, prostate or seminal vesicles in the male, even though no obstruction exists in the lower urinary tract and the ureterovesical sphincter is intact In the female a similar transport of organisms from the bladder to the kidney can occur Bauereisen[9] has recently directed attention to the anastomosis of the lymphatics of the internal genitalia with those of the bladder and ureter He believes that some of the cases of cystitis following gynecologic operations are due to this communication In some of the experiments of our first series the tendency of the inflammatory changes to follow the course of the periureteral lymphatics was very striking It is quite possible that the pyelitis of pregnancy and the puerperium may be due to the migration of organisms from the genitalia directly to the periureteral lymphatics without the presence of an accompanying cystitis Our work would also offer the most plausible explanation for the pyelitis of infancy and childhood, which occurs predominantly in girls Infection of the bladder in such cases from the vulvovaginitis, so commonly present, with ascending infection by way of the interstitial lymphatics of the ureter, can readily occur

CONCLUSIONS

1 While infection of the bladder or lower ureter may reach the renal pelvis or the kidney either by way of the lumen of the urinary tract or by way of the mural lymphatics, experimental and clinical evidence indicates that complete or almost complete obstruction to the urinary outflow is necessary for ascent of infection by way of the lumen of the urinary tract

2 We have shown experimentally that in the absence of complete obstruction the infection may and does pass upward from the bladder by means of the lymphatics of the ureteral wall

3 Depending on the virulence of the organism and on the susceptibility of the host, the involvement may

---

[9] Bauereisen Ztschr f gynak Urol 1914, 4, 1

remain limited to (1) the bladder and ureter, (2) it may pass upward to the pelvis, or (3) it may invade the renal tissues When the kidney itself becomes involved, the inflammatory agent is carried from the renal pelvis to the parenchyma by the lymphatics of the intertubular and perivascular tissues

4 In the human being the lymphatic network constitutes the most important path of ascending infection when pyelitis or pyelonephritis follows cystitis not associated with complete obstruction to the urinary outflow

5 In the absence of cystitis the renal pelvis or the kidney itself may become involved by the transport of infection from the pelvic organs or from the lower intestinal tract through the anastomosing lymphatic channels, which anatomic study has shown to be present

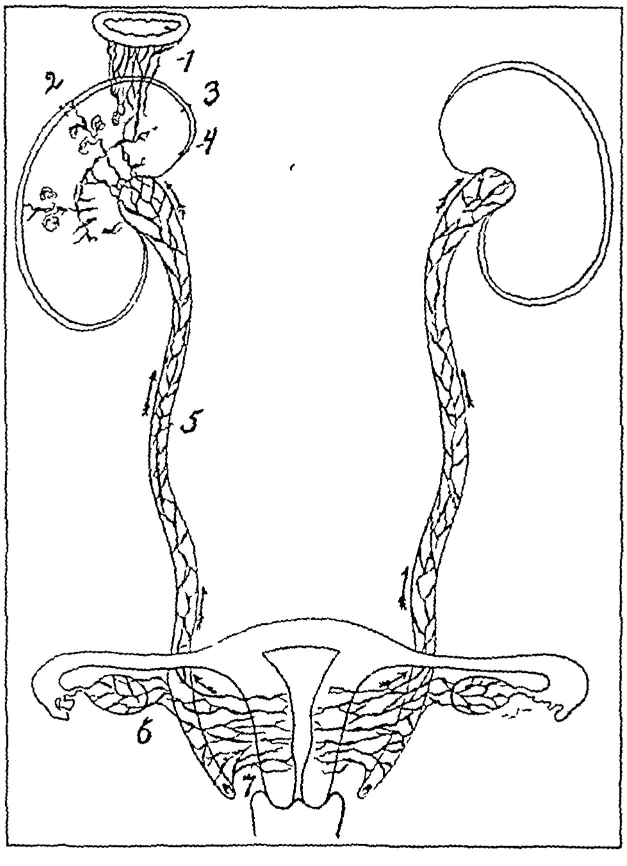

Fig 3—Relation of lymphatics of the ureter to those of the internal genitalia of the female and to the colon 1 lymphatics from colon to cortex of kidney, 2 3 and 4, periglomerular boundary zone and inter tubular lymphatics of kidney (Kumita) 6 communication of periureteral lymphatics (5) with those of uterus, tubes and ovaries

ABSTRACT OF DISCUSSION

Dr G Kolischer, Chicago Up to recent years it was believed and stated in a kind of axiomatic way that there were only two sources of renal infection, the hematogenous infection and the direct Now it is demonstrated that micro-organisms may travel up into the kidney from the bladder, from the genitals, especially in the female, without being carried through the lumen of the ureter, they are carried through the lymphatics, without any obstruction, where the flushing from the kidney to the bladder is still intact This will do away with the indifference shown in certain quarters toward infection of the genito-urinary tract, especially in women It will be necessary to attend to all these processes in the lower genito-urinary tract in women very thoroughly, so as to prevent pyelitis, especially in women, and in pregnant women We will be able to save many cases which would become infected and lost otherwise

Dr E O Smith, Cincinnati Dr Kretschmer has shown in his cystographic work that even normal bladders have regurgitation of fluid into the pelvis of the kidney, so we may still have infection going up the ureter without obstruction, and there may be pyelitis without obstruction anywhere along the line of the ureter It has been demonstrated that the normal kidney will take care of a considerable amount of infectious material, and in order to have an infection of the kidney, even though it reaches the kidney through any one of the three routes, there must be something that is damaging that kidney A normal kidney will take care of perhaps all that will go through this lymphatic tract I would like to ask Dr Eisendrath to explain just why these pelves become infected without an infection of the kidney by the infection carried through the lymphatic stream?

Dr Edwin Beer, New York I do not quite see how one can conclude that the infection started in the lymphatic channel and not within the ureter I am firmly convinced that lymphatic infection along the ureter is very important Yesterday Dr Crabtree told me that in a series of about fifty cases of pyelonephritis they had a positive blood culture of colon bacilli in 30 per cent I would like to ask Dr Eisendrath whether he controlled his animals, took blood cultures, so as to disprove a hemic infection plus the lymphatic infection? My evidence of the importance of the lymphatic infection is in tuberculosis of the kidney In the earliest types of tuberculosis of the kidney one may find, and I have seen it, the tuberculous ulcer starting in the notch which Dr Eisendrath called attention to, the angle where the papilla is inserted into the kidney I do not think many of us doubt, from the experimental work that has been done that tuberculosis of the kidney is a hemic infection The interesting point brought out by cases I have observed, in which the ureter is removed secondarily, is the fact that the microscopic examination of the ureter will show in the great majority of cases that the mucous membrane is intact, but that there is a lymphatic tuberculosis, a periureteritis The question arises, Is there not an analogy between the tuberculous cases and the colon infections which would allow us to harmonize the results of the clinical observations of Cabot and Crabtree, and the experimental work of Eisendrath?

Dr Irvin S Koll, Chicago A few years ago I made bold to coin the expression "lymphomania," because I was afraid that our interpretation of the experimental work on kidney infection was becoming too reactionary Some of my earlier kidney experimental work shows definitely that we are overestimating the importance of the lymphatic tract There can be no doubt that the lymphatics carry a large percentage of the infections of the kidney from the lower urinary tract, but I can present a number of sections from the kidney that show definitely that we get a distinct glomerulitis without any evidence of round cell infiltration around the lymphatics

Dr Daniel N Eisendrath Chicago We made blood cultures on every known medium on every animal that was killed (they were killed with strychnin), in a thorough bacteriologic manner, and in not a single case did we find a positive culture from the blood Furthermore, we made cultures from the urine in every case, and did not find a positive result in that At necropsy, in addition to cultures from the blood, we made cultures from both kidneys and from the bladder, and in a number of these we recovered the same organism which we injected Dr Smith brought up a point which I am going to bring out in the paper, the longer an experiment lasted, the less did we see In other words, it seemed that what we found was frequently not possible of clinical demonstration over eleven days after the animal became infected We see first little traces of infection in the bladder, and perhaps up the ureter a few little cells, nothing else My belief has always been that we seldom, if ever, get a pure pyelitis, that there is almost invariably an infection of the parenchyma of the kidney I think Dr Chute was one of the first to call attention to that In regard to the question which Dr Beer raised as to the transmission within the kidney itself, I am becoming more and more convinced that after the infection once starts in a single place, it travels from that into the kidney itself That is something we are working on now, the intrarenal lymphatics That is the only way in which we can explain some of these cases in which there are five or six foci not connected with each other I believe the same thing is true of tumors If a hypernephroma starts in one portion of the kidney we can explain its spread to distant parts in that way Dr Koll stated that he found a glomerulitis and no evidence of inflammation I cannot reconcile the two statements

---

TWO CASES OF TRICHOPHYTOSIS BARBAE CURED BY THE USE OF STRICKLER'S RINGWORM VACCINE*

M F ENGMAN, M D, AND R A McGARRY, M D, ST LOUIS

Owing to the results obtained by the use of Strickler's ringworm vaccine[1] in two cases so treated, it is felt that their publication may be of stimulating interest In undertaking the treatment of these cases, both of *Trichophyton megalosporon-ectothrix,* little hope was entertained that the results would be so striking, as the directions for use in the package kindly sent us by Dr Strickler stated that practically all the cases in which it had been used were of the microsporon type

The patients under discussion were both Italians, swarthy, with coarse skins and black, heavy beards

CASE 1—F F, aged 22, freight handler, with negative physical examination, first became aware of the trouble four weeks previous to his entrance into the hospital A small pustule appeared on the lower lip This was soon followed by others, and the disease rapidly spread over the entire bearded region of the face (Fig 1) Various remedies were tried, with no result

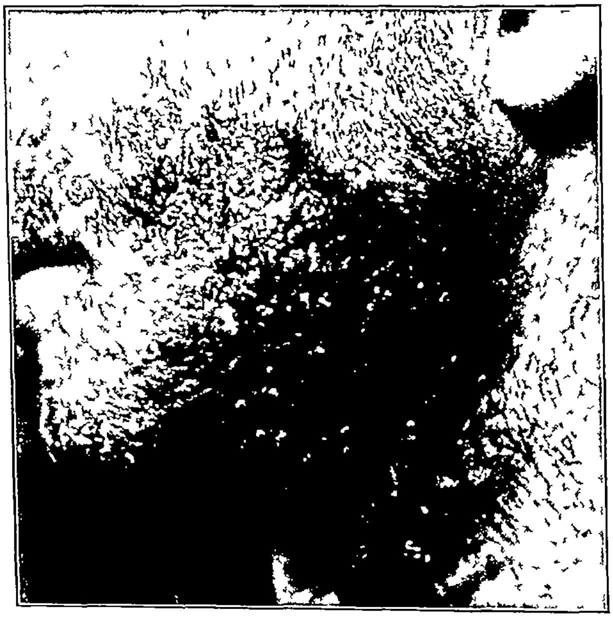

Fig 1—Before use of vaccine

With the exception of the small area around the mouth and that just in front of the ears, the entire bearded region of the face and neck was involved and there was a similar area on the left forearm The beard was long and had not been shaved for two weeks The face was swollen There was some redness, with local edema, and the lesions were all infiltrated, particularly in the submental region A large number of yellow pustules involving the hair follicles covered the entire face In some places they were clumped into little tumors or nodules The hairs were so easily extracted that they came out with the plain petrolatum dressing

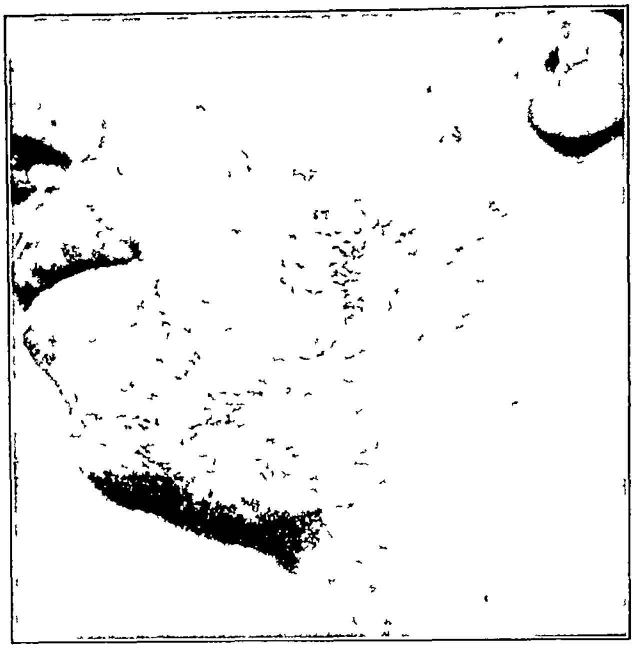

Fig 2—After use of vaccine

CASE 2—S C, aged 27, laborer in a spaghetti factory, could impart little of his history, as he only spoke an Italian patois Physical examination was negative It was learned later that two other males in the family had similar trouble

On entrance to the hospital the right side of the face was greatly swollen, with a suggestion of abscess formation at a point just inferior to the angle of the jaw Considerable inflammation and a slight amount of induration were present Minute pustules were noted around the base of the lesion and scattered over it, pierced by a hair An area about the size of a half-dollar had become almost denuded of hairs in the tip of the tumor, and the pus came from some of the follicles in this area Around the border of the clear area were small verrucose growths, giving it a cobblestone appearance

Microscopic examination of both cases disclosed the *Trichophyton megalosporon-ectothrix* fungus

Both patients remained in the hospital throughout the treatment Nothing was applied locally except plain petrolatum The period between injections was six days All injections were made subcutaneously between the scapulae

Patient 1, March 18, was given an initial dose of a full ampule 2 c c, of the vaccine as prepared by Dr Strickler

March 21, the temperature of the patient was 100 F , March 23, normal On the evening of this day, however, the patient complained of a severe pain in the upper right abdominal quadrant The temperature rose to 100 5 F The surgeon was called in consultation, and a diagnosis of acute cholecystitis was made Hot packs and the usual remedies were applied, and the patient immediately recovered

He was given a second ampule, March 28, when the face began to improve The inflamed appearance had markedly decreased and the edema had subsided

May 13, the patient was dismissed cured, there being no evidence whatever of the disease (Fig 2) Six injections, in all, were administered

Patient 2 was given an initial dose of 2 c c of Strickler's vaccine, March 18

There was a slight local reaction March 21, the temperature rose to 101 F and gradually subsided by March 24

---

* From the Barnard Free Skin and Cancer Hospital

[1] Strickler Albert The Vaccine Treatment of Ringworm of the Scalp THE JOURNAL A M A July 17 1915 p 224

There seemed to be some increase in the swelling, the tissues felt more infiltrated, and the patient complained of considerable pain

The second injection was given March 24, after which no reaction followed Improvement had, however already appeared in the lesion The swelling was gradually subsiding, March 30, when the last injection was given

The patient was discharged, May 13, entirely free of the disease

The results in these two cases have been striking and, of course, far superior and far more quickly obtained than by any other method we have heretofore used

---

DECOMPRESSION CRANIOTOMY IN BULLET WOUND OF BRAIN AND HEMIPLEGIA

Junius Hardin McHenry, M D, New York

Associate Neurologic Surgeon, Polyclinic Medical School and Hospital

History—D M, man, aged 74, born in Ireland, of small stature, weight 120 pounds was brought to the Polyclinic Hospital in the evening of Jan 16, 1916 He was perfectly conscious, and gave his history frankly without showing any great excitement or any evidences whatever of shock He said that two men entered his small basement store and at the point of a revolver demanded money He gave them what he had, and in leaving one of them fired at him, striking him in the face just below the left eye Almost immediately he lost the sight of the left eye

Examination—Just below the left eye was a small ragged wound, the size of a bullet, from which blood was freely oozing There was also considerable hemorrhage from the left nostril This was controlled by packing the nose with gauze, but even then it continued to ooze for two or three hours afterward The temperature was 99, pulse 85 respiration 20 The left pupil was widely dilated, and did not react to either light or accommodation The wound was thoroughly cleansed, and with a probe, the course of the wound was determined to be upward and inward to the orbital bone No further attempt was made to locate the bullet For drainage a small piece of folded rubber tissue was inserted into the wound and a sterile dressing applied Three thousand units of tetanus antitoxin as a prophylactic dose were given intramuscularly, after which the patient was admitted to the ward on the service of Dr William Sharpe

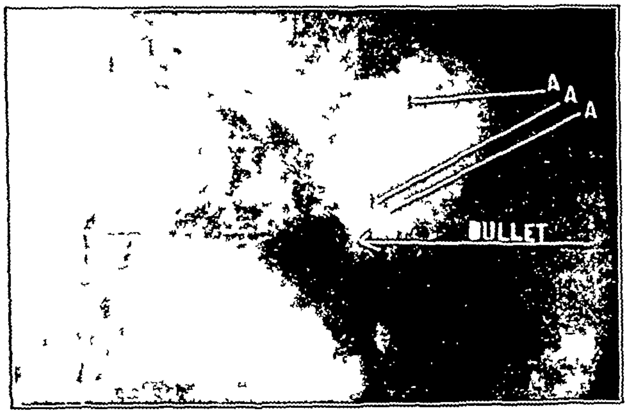

Fig 1—Location of bullet and fragments along its course *A A A* silver wireclips placed over branches of middle meningeal artery in the dura at the time of operation

The following morning January 17 we found the patient with a complete right-sided hemiplegia There were no signs of aphasia there were a Babinski reflex of the right foot and beginning signs of medullary compression The temperature was 100 pulse 60 respiration 16

The cerebrospinal fluid by lumbar puncture was found by measurement under pressure and blood tinged

Ophthalmoscopic examination revealed slight obscuration of the optic disk of the right eye, more marked on the nasal half

These signs were present 1 Hemiplegia of right side 2 Beginning signs of medullary compression, as evidenced by lowered pulse rate, rise in temperature and diminished respiration 3 The cerebrospinal fluid under pressure, shown by lumbar puncture and ophthalmoscopic findings

The combined symptoms and signs of hemorrhage on the brain together with other clinical signs, were also positive

Fig 2—Patient Oct 10, 1916, aged 75

Operation—I performed a left cranial decompression A vertical incision was made in the skin from a point just above the zygoma, on the left side about one-half inch anterior to the external auditory meatus upward about 3 or 4 inches to the middle of the parietal crest The temporal fascia and muscle were incised longitudinally and retracted care being taken not to tear away the attachment of the muscle to the parietal bone and thereby weaken its closure With a Doygen perforator and burr a small opening was made in the lower and thinnest portion of the squamous portion of the temporal bone With rongeurs the bone was cut away as far back as the retracted muscle would permit in an oval shape to the diameter of 2 or 3 inches The dura appeared tense and distinctly bluish underneath When it was incised, quite a quantity of free dark blood escaped, but no clots were found After the flow of blood ceased there was no evidence to be seen of any injury to the cortex No attempt was made to search for the bullet (the location of which is shown in Figure 1) The dura was opened in a stellate manner and left so A folded rubber tissue drain was placed in the lower angle of the wound subdurally into the middle fossa, then muscle, fascia and skin were securely sutured Sterile dressing and roller gauze bandage were applied to the head and the patient returned to bed in good condition The temperature was 99 6 the pulse 78, and the respiration 22

Postoperative Course—The wound healed by primary union There was temporary incontinence of urine and feces A discharge from the left eye ceased February 1 The left eye was totally blinded There was no impairment of vision of the right eye March 19, the patient was discharged with complete use of the right arm and hand, he still walked with the aid of a cane but did not drag the foot He has now passed his seventy-fifth birthday (Fig 2) walks without a cane, is as mentally bright as before his accident and continues to carry on his business—a small grocery store He does not drag his feet and has a firm grip to his right hand The present weight is 118 pounds

SUMMARY

The patient has always lived a temperate life, but his complete recovery, I believe, can be summarized as follows

1 Prompt surgical relief of intracranial pressure before the onset of medullary edema with signs of compression or shock

2 Release of subdural hemorrhage before any injury to the cortex from irritation by the formation of blood clots

3 Selection of the subtemporal route with vertical incision for the decompression operation thereby giving best opportunity for drainage and also perfect closure over the removed bone area

COAGULATION TIME OF THE BLOOD IN PNEUMONIA *

GEORGE R MINOT, MD
BOSTON
AND
ROGER I LEE, MD
CAMBRIDGE, MASS

A recent article in The Journal[1] on the coagulation of the blood in pneumonia seems to us rather misleading, not only in its deductions but also in the methods employed

Anders and Meeker determined the coagulation time by obtaining blood from puncture of the ear or finger Any such method of obtaining blood for determining the coagulation time is so clearly open to error that it should be discarded While the method of obtaining blood by venous puncture and allowing it to clot either directly or by recalcifying the oxalated plasma at room temperature in glass tubes evidently intrudes artificial conditions, which doubtless interfere somewhat with accuracy, nevertheless it can be emphatically stated that the obtaining of blood by rapid venous puncture is a necessary step in making observations of any value on the coagulation time of the blood [2]

The main reason for insistence on this point is that all tissues contain a substance (tissue juice, thrombokinase, thromboplastin, cytozyme, etc), which is a potent factor in coagulation and is similar to the action of the blood platelets, which markedly hasten coagulation of the blood For the purpose of determining coagulation time, blood should be obtained in as near the natural state as possible, so that the platelets, etc , are not unduly altered or the initial stages of coagulation unduly hastened Tissue puncture of the ear or finger necessarily introduces some of the "tissue juice" into the blood and allows the blood to be unnecessarily altered and thus vitiates observations of coagulation time

Lee and White,[3] among others, have already shown that a normal coagulation time of blood from the ear is of no significance unless delayed We have repeatedly observed a normal coagulation time when blood was obtained from the ear, but a delayed time when blood was properly obtained from a vein In cases of hemophilia, for example, blood from a vein showed a marked delay in its coagulation time, while blood from the ear frequently clotted in normal time There is, of course, no doubt that the true coagulation time is usually markedly prolonged in true hemophilia From such observations it seems clear to us that the coagulation time should always be determined with blood drawn by a clean puncture of a vein rather than with blood by puncture of the skin with the inevitable introduction of additional coagulating factors

Anders and Meeker[1] found the coagulation time of the blood in pneumonia shorter than normal before the crisis and essentially normal after it On the other hand, other workers, and particularly Dochez,[4] to whom they make no reference, showed quite the reverse condition Dochez found during the disease usually a delay, never a shortening in the coagulation time, which became normal shortly after the crisis Dochez suggested that, together with the recognized increased fibrinogen in the blood in pneumonia, there might be an increase in antithrombin to account for the delayed coagulation time Dochez used a careful and excellent technic for determining the coagulation time of the blood, which was drawn from a vein Our results from a study of twenty cases (six previously reported[5]) which were obtained by a similar though cruder method[3] in that ordinary small glass tubes were used and the observations were made at room temperature, are entirely in accord with those of Dochez We never found the coagulation time less than normal It was nearly always delayed, at times quite markedly so, more usually in very sick patients The coagulation time became essentially normal shortly after the crisis Our figures show variations from six and one half to thirty-eight minutes, usually from fourteen to eighteen minutes for the coagulation time in the cases of pneumonia before the crisis A long series of normal controls vary between five and ten minutes

Our observations have not as yet reached a point at which we feel that we can state positively the exact nature of the interference with the normal complicated mechanism of coagulation which prolongs the coagulation time in pneumonia We have, however, made the following observations on the blood in pneumonia The clots retracted in apparently normal fashion Some clots retracted rather weakly, coincident with a diminished number of platelets The reclotting phenomenon was observed in three cases in which a marked delay in the coagulation time was noted This reclotting phenomenon in the blood of pneumonia is quite similar to some other observations (reported[5] and unreported) in other groups of cases which showed a delayed coagulation time The red cells in the oxalated plasmas of our cases settled out with remarkable rapidity, and this also frequently occurred in the whole blood, as shown by the white character of the upper part of the clot even in those bloods which clotted in but slightly delayed time This phenomenon is perhaps associated with an altered viscosity of the blood In twelve of our cases the prothrombin time[6] (the time required for a given amount of oxalated plasma to clot in the presence of the optimum amount of calcium) was estimated and, like the coagulation time, was usually delayed, although our impression is that it was usually relatively less delayed than the coagulation time

The optimum amount of calcium required to determine the prothrombin time was the same for the pneumonia plasmas as for the controls, thus illustrating that there was ample available calcium for the purposes of coagulation [7] The antithrombin, determined by a modification of Howell's method,[8] was usually normal, in some cases high, and rarely slightly diminished These variations are unexplained They did not occur in any definite relation to the prothrombin time or the coagulation time The fibrinogen was increased, as has often been observed In three instances in which we found the antithrombin normal but the prothrombin time and coagulation time delayed, it was noted that the oxalated plasmas of the pneu-

monia blood clotted slightly faster than the control plasmas when equal suitable amounts of either a fresh suspension of blood platelets or kephalin (active thromboplastic substance) solution were added with appropriate amounts of calcium. One possible explanation is that with the excess of fibrinogen there is presumably some other altered relationship in the character or amount of other coagulating factors, so that when any one substance which accelerates the coagulation is introduced into the plasma, the initial stage of coagulation is more readily started or more quickly completed.

Furthermore, with perhaps an excess or altered character of the factors entering into the late stages of coagulation in which fibrinogen participates, the complete coagulation time is shortened. Such might explain the results obtained by Anders and Meeker, since by their technic there must have been introduction of some "tissue juice" and some undue modification of the platelets. Under these circumstances, the first stages of coagulation were perhaps completed in normal fashion, and the later stages were permitted to proceed more rapidly than normal. This would suggest that in the blood in pneumonia there may be a lack of the substance akin to "tissue juice," or increased need of it. With the methods used by Dochez and ourselves, there is much less interference with the initial stages of coagulation, and consequently we have found the coagulation time quite constantly delayed in our cases of pneumonia.

A few words in regard to the role of calcium may not be out of place, since Anders and Meeker discuss the role of calcium in coagulation.

The importance of calcium in coagulation has long been recognized. Because calcium can be readily administered, it has been used widely as a therapeutic agent in all sorts of pathologic hemorrhage. There is much confusion concerning the efficiency of calcium therapy. Most of the reports are without value, as they are either frankly clinical or depend on tests of coagulation time of blood taken through the tissues. In observations of pathologic coagulation of blood, at the bedside, in experimental animals and under all sorts of abnormal conditions in the test tube in the laboratory, we have so far been able to ascribe only one condition of abnormal coagulation time of clinical significance to a lack of calcium. The condition is common in obstructive jaundice of several weeks' duration. In this condition the amount of calcium is actually increased, but there seems to be insufficient calcium available for purposes of coagulation. This lack of available calcium can be corrected by the administration of large doses of calcium salts clinically, in the test tube and in experimental animals.

CONCLUSIONS

The determination of coagulation time of blood is at best uncertain under the necessarily artificial conditions of any test. Determination, however, of the coagulation time of blood obtained by neat technic from venous puncture seems to be reasonably accurate. Observations of coagulation time of blood taken through the tissues is obviously unreliable. The coagulation time of blood in pneumonia is generally prolonged. The deduction on the basis of tests made by ear puncture that the coagulation time of blood in pneumonia is shortened is unwarranted.

DOES THE SPINAL FLUID FROM HUMAN POLIOMYELITIS CONTAIN THE SPECIFIC INFECTIVE AGENT?*

H. L. ABRAMSON, M.D.
NEW YORK

Repeated attempts to demonstrate the virus of poliomyelitis in the spinal fluid of human poliomyelitis both by cultures and by animal inoculation have all proved negative. Flexner and Lewis[1] have demonstrated its presence in the spinal fluid from an infected monkey drawn three days after the time of the intracerebral injection of virus. This fact suggests that it may be present in the fluid at some stage of the incubation period. If it is present, it is probable that it diminishes rapidly with onset of the symptoms, but may not wholly disappear. It is possible that the virus is present in the later stages in such minute quantities that it cannot be demonstrated by animal inoculation.

Nuzum and Herzog[2] have recently reported the finding of a gram-positive coccus in 90 per cent. of the spinal fluids from positive cases of acute poliomyelitis. This organism was isolated with apparent ease, even from spinal fluids withdrawn several weeks after the onset of paralysis. The organism was grown under aerobic conditions and subcultures grew readily on glucose agar slants.

During the epidemic in New York City, this laboratory cultured upward of 1,200 fluids from patients with acute poliomyelitis in all stages of the disease. The medium used was 1 per cent. glucose ascites agar under aerobic conditions. Except for a few evident contaminations, our cultures remained sterile.

The experiment here recorded was undertaken to determine whether or not the aggregate of a number of spinal fluids from positive cases of human poliomyelitis contains sufficient virus to infect a monkey.

The fluids from forty patients with poliomyelitis were centrifuged at high speed for three quarters of an hour. As our clinical work consists chiefly of the diagnosis of suspicious cases, these fluids were derived from cases early in the disease, most of them in the preparalytic stage. The sediments, amounting to 1 c.c. of very turbid fluid, were injected intracerebrally into Rhesus 23. Culture tubes of glucose ascitic agar inoculated with some of the sediment remained sterile.

No effects were noted, and after an observation period of two months, this animal was inoculated with 0.5 c.c. 10 per cent. suspension of VII gen. monkey virus. After an incubation period of eleven days, paralysis appeared in the left leg. The paralysis then involved the right leg but failed to progress further. The animal is alive and improving.

CONCLUSION

It would appear from the foregoing experiment that there is present little, if any, virus demonstrable either by culture or animal inoculation in the fluids of human poliomyelitis in the early stages.

LONG NITROUS OXID OXYGEN ANESTHESIA REPORT OF CASE

J R McCurdy, M D Pittsburgh
Chief Anesthetist Western Pennsylvania Hospital

The opinion seems to prevail among those who have had no experience with gas' anesthesia that it is useful only in minor surgery, for operations requiring only a brief anesthesia and for operations of necessity on patients who cannot withstand the depression or acidosis produced by ether or chloroform Those who have done considerable operating under nitrous oxid oxygen anesthesia know this opinion to be a fallacy Almost any operation can be done under it, and it should unquestionably be the anesthesia of choice where there is the least possibility of the patient's chances of recovery being lessened by operative shock or postoperative depression or acidosis Cases in which it has been used in major surgery for operations of from one and a half to three hours are by no means rare A few cases of four hours' duration have been reported But as far as my search of the literature has disclosed there is no case on record as long as the one herewith reported—four hours and forty minutes

REPORT OF CASE

History—Mrs H, aged 72 well developed, admitted May 2 1916 had acute intestinal obstruction A diagnosis of carcinoma of the sigmoid was made The cecum was enormously distended with fecal matter Cecostomy and appendectomy were done under nitrous oxid oxygen, the operation lasted ninety minutes and anesthesia was uneventful The patient was discharged May 13, with an artificial anus Since then she had had complete obstruction of the lower bowel She was readmitted, October 9, for sigmoidectomy and closure of the fecal fistula Operation was performed, October 10 under nitrous oxid-oxygen anesthesia, preceded by morphin sulphate, ⅙ grain hypodermically An incision in the left lower quadrant was 'blocked" by novocain, 1 400 and quinin and urea hydrochlorid, 1 500 Sigmoidectomy was performed with great difficulty, and then a lateral anastomosis of the colon The incision was closed The old cecostomy wound was then opened without 'nerve block" and portions of the cecum and ileum were found to be bound in an indescribable mass and riddled with sloughed openings It was necessary to perform three separate anastomoses removing as many portions of the bowel

Anesthesia—Induction proved a trifle difficult owing to spasm of the jaws and unfavorable condition of the teeth This rendered breathing difficult and unsatisfactory until relieved by insertion of a Ferguson-Hewitt artificial airway after which respiration was quiet and even Operation was begun five minutes after the anesthetic had been started Three and one half ounces of ether were used throughout the four hours and forty minutes, being administered with the gases at irregular intervals chiefly during the early part of the first stage of the operation, to secure greater relaxation of muscles The patient's color remained good throughout (after insertion of the airway), and the highest respiration rate was 32 The preanesthetic pulse was 84, and the rate did not go above 100 until the last half hour, being 116 immediately after the anesthetic No stimulants were employed until within fifteen minutes of the end of the operation, when 20 drops of camphorated oil were given, followed in five minutes by ⅙ gram of morphin sulphate There was only occasional retching and no vomiting except once immediately after the anesthetic was removed The patient was conscious and replied to questions five minutes after

Postoperative Course—The patient left the operating room at 3 10 p m, the pulse was 116, and respiration 26 The feet and legs were slightly cold and cyanotic, though the entire skin was dry At 4 p m, the patient complained of dyspnea Atropin sulphate ¹⁄₁₀₀ grain was given hypodermically The patient complained of being too warm

At 4 25 p m, the pulse was 112 and respiration 20 Oxygen inhalation was given for five minutes

At 5 p m the pulse was 114, respiration 20 and temperature 97 The color and skin condition were good From this time to 11 30 the patient continued in remarkably good condition Just before midnight the pulse became rapid and thready, respiration progressively labored, and temperature rising From then on there was only brief response to stimulation, and symptoms suggested acute cardiac dilatation Death occurred at 5 30 a m

COMMENT

In just what degree, if any, the long anesthesia contributed to the fatal termination can only be conjectured The case is cited to show that long sustained nitrous oxid oxygen anesthesia is feasible, and that difficult operations can be performed under it which could not be completed under ether or chloroform

DELIVERY UNDER GAS AND OXYGEN OF TWO PATIENTS WITH LOST CARDIAC COMPENSATION

W T Getman, M D, Buffalo

Case 1—Mrs F S aged 32 sextipara, had had measles when a child, no illness since and no history of rheumatism or infectious disease For three years she had been troubled with dyspnea and swelling in her limbs so that it was difficult to do her housework For the past seven months she had been unable to walk or to sleep except when sitting up Edema increased steadily

Examination on admission to the Buffalo General Hospital revealed great edema of the feet legs thighs, vulva, abdomen and face The heart was dilated and very irregular The apex beat was just outside the anterior axillary line A systolic murmur was heard over the entire cardiac area The hemoglobin was 58 per cent The urine showed a trace of albumin and a few granular casts A diagnosis of mitral insufficiency with lost compensation was made

The patient had been pregnant eight and a half months She had had no difficulty in her five previous labors, and her pelvic measurements were normal For nine days after admission she was in the medical ward in the service of Dr De Lancey Rochester and by the Niemeyer pill and strychnin the edema was somewhat reduced and the dyspnea slightly improved, though she still had to sleep in the sitting posture

When her labor commenced she was transferred to the obstetric service She stood the first stage pains fairly well, but when expulsive efforts began at the end of dilatation, she became cyanosed and almost pulseless I decided on version and extraction, and as ordinary anesthesia was out of the question, she was brought to the end of the delivery table in a sitting position nitrous oxid and oxygen were administered, and she was delivered of a full term living child in five minutes by version She stood the gas and oxygen nicely, and in the week following improved rapidly being able to sleep lying down and having little dyspnea On the ninth day after confinement while perfectly quiet, she suddenly developed acute cardiac dilatation and died six hours later

McKenzie states that a pregnant woman with lost compensation is in danger of acute dilatation for at least two weeks after delivery

Case 2—Mrs N B, aged 43 primipara, had had a mitral regurgitation for five years She had attacks of cholecystitis at intervals Eleven years before she had had a ventral suspension done for retroversion For three months she had noticed edema of the feet and legs, and had had to sleep sitting up on account of dyspnea

The heart was dilated and irregular The apex beat was 1 inch outside the nipple line The child was lying in the transverse position, probably on account of traction on the fundus from ventral suspension As the patient was a primipara, version and extraction could not be considered, and cesarian section under gas and oxygen seemed the safest

Three days before her estimated date of confinement, I did a high Davis operation and delivered a living full term child The operation was completed in thirty-five minutes under light gas and oxygen anesthesia and the patient made an uneventful recovery, leaving the hospital in two weeks

I am reporting the delivery of these two patients under gas and oxygen as I think neither patient would have survived an ordinary labor with any of the anesthetics ordinarily used

Therapeutics

DISTURBANCES OF THE KIDNEYS

(Continued from page 461)

Nephritis

DISTURBED FUNCTION IN NEPHRITIS

Aschoff[72] states that the majority of primary contracted kidney cases develop as a result of vascular disturbance, "a sclerosis of the finest branches of the renal artery beginning relatively early in life and leading secondarily to the formation of atrophic foci in the parenchyma and to hyaline degeneration of the glomeruli, with a resultant focal inactivity and atrophy of the tubules belonging to them " The whole process is slow and passive This slowly developing sclerosis of the fine arteries of the kidneys causing typical Bright's disease is not similar to the arteriosclerotic kidney of later life, when aortic disease precedes it, as in the latter case some parts of the kidneys may not be involved It is self-evident that the more filter tissue incapacitated by arteriosclerosis the more efficient must be the circulation in the healthy parts of the filter Hence the high blood pressure, cardiac hypertrophy and polyuria is nature's compensatory mechanism Furthermore, the healthy glomeruli of the kidneys may hypertrophy so as to make the excretion from the kidneys sufficient without the assistance of the impaired sections

In secondary contracted kidneys the previous history is that of an inflammation In these cases the whole kidney filter is involved and the kidneys cannot react to any emergency demand on them, hence edema and uremia frequently occur Usually a diminished amount of urine is passed, sometimes resulting in polyuria In this condition the metabolism is the same as in primary contracted kidneys, namely, there is increased blood pressure, etc

Tests of function will show the ability of the recovered or still intact portions of the kidney to excrete, but do not show the excretory ability of the scar tissue It has also been demonstrated by Baetjer[73] that in certain conditions of nephritis there may be not only a normal but also an increased eliminative power at some particular period Hence one test, and even a repeated test with one substance, is not sufficient to demonstrate the health of the kidneys

In the secondary contracted kidney the tubules connected with each diseased glomerulus gradually lose their power to function, to a greater extent than in primary contracted kidneys The larger the number of glomeruli impaired or entirely incapacitated, the less the amount of urine excreted The polyuria of hypertension and the consequent increased circulation in the unimpaired glomeruli should not be confounded with the polyuria caused by irritative toxins which injure the filter apparatus Rapid impairment of normal function occurs in acute nephritis

Oertel does not find that the amount of contraction of the kidneys bears any relation to the amount of cardiac hypertrophy

Unless there is urea and nonprotein nitrogen retention in the blood, some other cause than kidney lesions is usually responsible for hypertension Lead, once a common cause of contracted kidneys, is now of little importance ordinarily, as workers in lead exercise more care than formerly Accidental chronic lead poisoning, however, from water pipes, hair tonics, etc, is still not of uncommon occurrence, although this cause of chronic nephritis, arteriosclerosis or other systemic disturbance is probably many times overlooked

Ophuls[74] says that subacute and chronic glomerulonephritis, in the majority of cases, is due to chronic sepsis, hence the danger, long unrecognized, of chronic infection of the mouth, nose and adjacent sinuses After the study of a thousand necropsies, Ophuls reaches the conclusion that the amyloid kidney, subacute and chronic (the so-called large white kidney) is also the usual result of chronic sepsis

An interesting estimate of the general resistant power of the system in the nephritis of acute infections is suggested by Carles and Mauriac,[75] namely, that the more serious the infection, the more fragile the leukocytes, also that leukocytes break down more readily in nephritis than in health This difference in their fragility in nephritis and in health, with the same technic, they find to be 50 per cent Consequently, even a mild complication of nephritis in acute infection makes the prognosis grave

Probably all poisons act primarily on the different parts of the convoluted tubules, the resulting variations in function being due to the parts of the kidneys most affected and to the effect on the blood pressure

PRACTICAL INTERPRETATIONS OF EXPERIMENTAL NEPHRITIS

Uranium is perhaps the irritant most frequently used to produce experimental nephritis Fitz[76] has shown that in acute uranium nephritis in rabbits the excretion of amylase is reduced and the nonprotein nitrogen of the blood is increased during the inflammation, but that the excretion returns to normal as the kidneys heal

Mosenthal[77] has shown that all grades of nitrogen retention may be caused by varying the dose of uranium With large doses the nitrogen excretion is diminished With small doses the nitrogen not only may remain normal, but even may be increased This he thinks may be due to the irritant causing a greater destruction of nitrogen in the body He believes that a greater excretion of nitrogen by the intestine does not necessarily mean a vicarious elimination, representing, perhaps, only an increased nitrogen metabolism The nitrogen output in the urine may be decreased even when the bulk of urine passed is sufficient This seems to indicate that nitrogen is excreted by the convoluted tubules, but does not prove that the circulation of the glomeruli is not disturbed in uranium nephritis

Underhill,[78] and later Underhill in collaboration with Wells and Goldschmidt,[79] showed that subcutaneous injections of sodium tartrate caused degeneration of the tubular epithelium From later experiments he concludes that the convoluted tubules excrete urea, and that the glomeruli excrete chlorids and water

[79] Underhill Wells and Goldschmidt Jour Exper Med **18**, No 4

Oertel,[80] in reviewing the subject of experimental nephritis, finds that when the sodium chlorid excretion is interfered with the urine concentration is low, when there is a diminished amount of urine excreted lactose excretion is slow, but sodium chlorid and potassium iodid excretion is normal, and in these instances the trouble is largely vascular, and when there is polyuria there is vascular hypersensitiveness

More recently Myers, Fine and Lough[81] have studied the retention of creatinin, uric acid and urea in the blood in nephritis, and conclude that a uric acid retention without urea or creatinin retention shows early interstitial nephritis Later in the disease urea is retained, and still later, creatinin Kraus[82] had already shown that creatinin is more or less retained in acute uranium nephritis

Frothingham, Fitz, Folin and Denis[83] found that in uranium experimental nephritis the excretion of phenolsulphonephthalein and the nonprotein and urea retention in the blood followed the course of the inflammation and returned to normal when the kidneys healed, and varied with the amount of kidney tissue involved The recovery of the permeability of the kidneys to phenolsulphonephthalein may be rapid in this experimental nephritis, the test showing the condition of the kidneys at that particular period, but nonprotein nitrogen and urea may be much longer retained in the blood, and consequently the blood test for nonprotein nitrogen is a more positive indication of the condition of the kidneys

Other poisons used in causing experimental nephritis or which accidentally cause acute irritant nephritis are chromium, mercuric chlorid, cantharides, croton oil, sodium arsenate and crotalus venom

Without edema there is probably no retention of chlorids

It seems to have been demonstrated[84] that, in experimental nephritis, diuretics, even the simplest, are irritant and harmful to the kidneys, and even if there is temporarily an increased output of urine and solids, there soon is a diminution of this output, and the lives of the animals are shortened This coincides with the clinical findings that in most cases of nephritis, certainly in all cases of acute exacerbations in chronic nephritis and in acute nephritis, diuretics are harmful

It seems to have been demonstrated that anything which increases the creatinin of the blood in nephritis, as muscular exertion or physical strenuosity, or infection or fever, adds to the danger from the kidney disease

Brown[85] showed that hematin poisoning of the kidneys may occur during severe malarial intoxication, and that all grades of degeneration of the tubular epithelium may occur, with albumin, casts and blood in the urine

Leopold and Bernhard[86] find that the nonprotein nitrogen of the blood, and the phenolsulphonephthalein test have the same values during health and in renal disease in children as in adults

Zondek[87] believes, after carefully studying children with nephritis and with orthostatic albuminuria, that if the nephritis is of the vascular type and the glomeruli unable to excrete sodium chlorid and urea, the tubules assume this extra work Hence, if the intake of salt is reduced, the tubules are better able to attend to excretion of nitrogenous substances, therefore, in glomerular inflammation, that is, vascular disturbances, it is not necessary to exclude nitrogen and salt from the diet at the same time In other words, if proteins are temporarily excluded from the diet, a little salt may be allowed Zondek found that by excluding salt the residual nitrogen of the blood was greatly reduced These findings suggest variations in diet

O'Hare[88] has studied the excretion of sodium chlorid, nitrogen and water in nephritis In normal individuals he found that on an increased sodium chlorid and nitrogen diet the urinary excretion became normal in forty-eight hours, but with diseased kidneys it may not return to normal in this period He finds that the excretion of sodium chlorid generally is impaired in nephritis before there is much disturbance of water or nitrogen excretion The excretion of nitrogen is greatly impaired only in severe cases Excretion of sodium chlorid, water and nitrogen may be impaired in mild cases, even with normal phenolsulphonephthalein excretion and normal nonprotein nitrogen of the blood

ANESTHESIA AND KIDNEY FUNCTION

It should be remembered that renal function as evidenced by one test of the phenolsulphonephthalein output is not sufficient, as this varies daily in a given patient If the phenolsulphonephthalein was markedly retained, one test would be sufficient as indicative of the condition of the kidneys, as far as anesthesia was concerned In advanced age the excretion of phenolsulphonephthalein is slower than normal, and this should be considered in operations on the aged

Renal function as estimated by the phenolsulphonephthalein test has been found by Miller and Cabot[89] to be generally decreased in operations under ether, and is especially decreased after laparotomies The decrease is best noted in the first twelve hours after the operation, and the more ether used and the longer the operation, the greater the decrease in the excretion of phenolsulphonephthalein, even to total inhibition in some instances Shock (low blood pressure) caused a marked decrease The lower the vitality of the patient, as from some serious condition like cancer, the more sluggish the phenolsulphonephthalein output They found no definite relation of the decrease of phenolsulphonephthalein excretion to postoperative albuminuria

Slemons and Morriss[90] have shown that the rest nitrogen is increased in both maternal and fetal blood after chloroform anesthesia

THE VENTILATION OF THE LUNGS IN PNEUMOTHORAX

In his well known essay on the factors of safety in the living organism, Meltzer[1] called attention to Nature's extravagance in furnishing most of the important organs with a large surplus of tissue above the amount necessary to perform their ordinary physiologic tasks This provision is a great blessing, serving to avert many a disaster which might follow impairment or a greater scantiness of functional matter Meltzer reminded us that life may continue though a great part of the lungs is destroyed, if only the disease which caused the destruction comes to a standstill In some cases of pneumonia one lung can be entirely consolidated without seriously impairing the process of ventilation Furthermore, a patient whose thorax is freely opened to evacuate a one-sided pleural abscess has less dyspnea after the opening than before In empyema, as in pneumonia, it is essentially the infection and intoxication with their reactions which cause the apparent disturbance in the respiratory mechanism, and not so much the mechanical interference with the ventilation of the corresponding lung Since the classic experiments of Regnault and Reiset, many investigators have stated that compression of one lung, or a unilateral pneumothorax, exerts little influence on the respiratory exchange of gases

An even more specific and, so to speak, quantitative study of this question has been reported in connection with an attempt to find out on man what effect a great reduction in the functioning lung surface would have on the various factors of respiration The observations were made in persons with pneumothorax by Means and Balboni[2] at the Massachusetts General Hospital, Boston They make it evident that at rest all the factors of respiration, gaseous exchange, carbon dioxid tension, and the mechanical factors, are normal in persons with a collapsed lung, that the well known reaction to carbon dioxid resulting in more rapid breathing is normal up to the point at which respiration is trebled or sometimes quadrupled, but that beyond this point a limit may be reached

Here again is clear evidence that the ventilation of the lungs can be accomplished in an entirely normal manner in spite of a greatly reduced vital capacity One lung is as efficient as two except when an increase at least threefold in contrast with normal ventilation is called for Means and Balboni have shown as the only difference between normal persons and persons with a collapsed lung that the latter when called on to increase their ventilation reach their limit a little sooner than the former Furthermore, the histories of patients bear out what might be expected in view of the foregoing, namely, that there will be no dyspnea in pneumothorax except after moderate exertion Thus does the liberal surplus of functional tissues prevent disease from hampering our activities or spoiling the pleasure of living

THE VENEREAL DISEASE PROBLEM—III

The English Venereal Disease Act

The order of July 12, 1916, of the Local Government Board puts in operation in England and Wales a system of state provisions for the diagnosis and treatment of venereal disease This order is practically an enactment into law of the recommendations of the Royal Commission on Venereal Diseases[1] Its detailed provisions so closely follow the recommendations of the commission that a consideration of them would be but a repetition of the analysis of the recommendations The essential purpose of the order is to furnish, as a sanitary measure, universal opportunity for prompt diagnosis and treatment of the venereal diseases The cost of this is to be met to the extent of 75 per cent from the imperial treasury, and only 25 per cent from local government funds Existing institutions are to be improved so that they can be utilized for this work, and new institutions are to be avoided as far as possible The venereal clinics are to be a part of general clinics, and every effort is to be made to relieve the scheme of the stigma of the venereal diseases

Facilities for diagnosis and treatment are to be furnished throughout England and Wales The institutions are to be accessible, evening clinics are to be provided, and embarrassing or deterrent restrictions are to be avoided as far as possible Treatment is to be given to all, regardless of their residence or means, but patients who are not objects of charity are to be referred, if possible, to private practitioners of their choice who, in conducting the treatment, are to receive the cooperation and advice of the medical officials in charge of the government clinics Arrangements are to be made for supplying salvarsan or its substitute to practitioners for the treatment of their patients The order shows evidence of appreciation of the importance of obtaining the cooperation of general practitioners, and of increasing the expert knowledge of venereal diseases among them The clinics are to be made centers of instruction for practitioners and students

[1] The Venereal Disease Problem—I editorial The Journal A M A, Feb 3 1917 p 375, II Recommendations of the British Royal Commission on Venereal Diseases Feb 10 1917 p 463

Like the report of the royal commission the order of the Local Government Board avoids radical steps It is a measure which carefully takes into account the social conditions under which it must be operated The privacy of the individual is not to be invaded His secrets are to be protected He is simply to be given universal opportunity for treatment and every effort made to induce him to avail himself of it The weak point of the plan, which apparently is unavoidable at present, is the fact that there are no adequate provisions for compelling attendance for treatment until the patients have passed beyond the contagious stage This is a requirement which sooner or later must be embodied in state measures for the control of venereal diseases The only body in the community which may regard the measure as a radical step is the medical profession The measure is socialistic in its tendencies, but so are most measures for the public good, and it is fully justified on the ground of its general importance as a sanitary measure to the whole people However much it tries to protect the private practitioner, it will tend somewhat to the sacrifice of his income That is true of every measure for the control of infectious diseases As past experience shows, this will not deter the medical profession in the end from giving the scheme its whole-hearted support It will doubtless have opposition until it justifies its existence by its results

The order is in many respects epochal It marks the first effort of an English-speaking country or, indeed, of any large state, to deal with the venereal problem on a large scale by providing facilities for diagnosis and treatment There is a vast difference between the state of public mind of so short a time as ten years ago, when it was impossible to get the English government even to appoint a commission to consider the venereal disease problem, and the state of public opinion today, which causes the government to put into the form of law the recommendations of a commission on venereal diseases within four months after its report is issued

This act presents under political and social conditions much like those of the United States, an organized effort by a state to reduce the prevalence of the venereal diseases by providing universal opportunities for treatment As such its results will be of great interest to us It may be said at once that the effort is well worth the making Whether or not it solves satisfactorily the problem of the venereal diseases, it gives every prospect of being of sufficient benefit to justify its cost It is to be hoped that it will obtain the support both of the medical profession and of the public to the extent necessary for its success

UREA AND UREMIA

The observation that normally the kidneys can excrete very large quantities of urea without evidence of what has been regarded as renal "fatigue"[1] might well stimulate an inquiry as to whether urea itself can manifest toxic properties in the body Now that it is understood to be far more difficult to raise the concentration of urea locally in the circulating fluid and tissues than was assumed before the days of modern detailed blood and tissue analysis, the possible harmfulness of urea itself in the body has lost some of its former probability Accordingly, instead of grossly ascribing the apparent intoxication in so-called uremia to urea, a more critical attitude has arisen It must be admitted today that, in certain patients toxic symptoms occur when the urea and the total incoagulable nitrogen of the blood are either not increased or are increased to such a small extent that the symptoms observed can hardly be attributed either to the urea or to an increase in the total incoagulable nitrogen of the blood This appears to be particularly true of those cases of uremia in which generalized epileptiform convulsions dominate the symptomatology In such cases particularly, the search for a specific toxic substance seems indicated, and N B Foster[3] has reported the isolation of a toxic base from the blood of patients suffering from the convulsive form of uremia As extremely large doses of urea seem, on the evidence of recorded investigations,[4] to be required to produce definite toxic effects in experimental animals, skepticism regarding the real toxicity of urea has further arisen

For these reasons, as Hewlett and his collaborators remark,[2] the view has become generally accepted that the toxic effects of urea in any concentration encountered in patients are negligible, and that the symptoms of uremia are due to the action of the other and more poisonous substances They have therefore undertaken the somewhat heroic and certainly disagreeable task of determining once again the possible toxic effects of urea by experiments in which men served as subjects The investigations of the level of urea nitrogen in the blood in well defined cases of uremia of characteristic asthenic type show that urea concentration is usually not less than 100 mg per hundred c c of blood, and that marked clinical symptoms almost invariably attend concentrations of 200 mg As urea diffuses rapidly from the blood into the tissues, the quantities of urea taken by healthy persons by mouth must be very large in order to attain comparable concentrations in the blood, particularly in view of the rapid elimination from the body by way of the kidneys in such normal subjects

[4] Herter C A and Wakeman A J On Alterations in the Composition of the Blood Resulting from Double Nephrectomy Jour Exper Med, 4 117 1899 Marshall, E K, Jr, and Davis D M Urea Its Distribution in and Elimination from the Body Jour Biol Chem, 18 53 1914

It was found that by giving approximately 100 gm of urea by mouth over a short interval of time it is possible to increase the concentration of urea in the blood of normal persons to levels of from 160 to 245 mg per hundred c c The investigators point out that such concentrations are comparable with those encountered in the asthenic type of uremia, and that if the symptoms in the latter condition are in any way dependent on the concentration of urea in the blood and tissues symptoms should occur under the conditions of their experiment They found, indeed, that at such levels of blood urea definite symptoms occur These consist of headache, dizziness, apathy, drowsiness, bodily weakness and fatigue These cerebral and bodily symptoms were most pronounced at the time of maximum concentration of urea in the blood

It seems probable, therefore, in the words of the authors mentioned, that when as a result of nephritis the blood urea exceeds a concentration of 150 mg per hundred c c, the symptoms of bodily and mental asthenia may be explained in part as being due to the high concentration of urea in the body fluids and tissues This by no means excludes the possibility that other substances may play a role in producing the symptoms of this type of uremia, indeed, the fact that animals die only when extraordinary doses of urea are administered suggests that the fatal outcome of asthenic uremia in man may be due to other substances than urea

BRAZILIAN TRYPANOSOMIASIS—CHAGAS' DISEASE

When we speak of human trypanosomiasis, we think only of the sleeping disease of Africa In Brazil, however, there occurs an entirely different form of human trypanosome disease, which was described in 1909 by Carlos Chagas[1] It was in the course of an antimalarial campaign that certain observations were made which led to the discovery of this "new disease" Chagas noted that patients with fever, lymphatic and thyroid enlargements, and other symptoms, but without malarial organisms in the blood, lived in houses which harbored an insect which sucks human blood Studying this insect more closely, he found that it contained trypanosomes, and by letting it bite monkeys and other vertebrates he could produce a form of trypanosomiasis In the next place, he found that the blood of infants in the region contained the same trypanosome, and by injecting guinea-pigs with such blood he could produce trypanosomiasis in them As one of the chief characteristics of the trypanosome thus discovered is sporulation without fertilization—schizogenesis—it accordingly was named *Schizotrypanum cruzi* The insect in question is known as *Conorhinus megistus* The cone-nose beetle, another species of the same genus, is widely distributed in the United States, and in some localities it may infest beds and suck human blood

The human disease caused by the *Schizotrypanum cruzi* is endemic in certain regions of Brazil and occurs there in various forms In infants it usually is an acute disease with fever and other general symptoms, enlargement of lymph nodes, of the spleen, the liver and the thyroid, with a kind of myxedematous condition of the skin, and trypanosomes in the blood Death may occur with meningo-encephalitic phenomena After from twenty to thirty days of acute symptoms, the fever may fall, the parasites in the blood diminish in number, and the attack pass into a chronic phase In older persons the disease usually is chronic, progressive enlargement of the thyroid is a marked feature, and there may be cutaneous pigmentation, muscular weakness, irregular heart action, and even cerebral diplegia While symptoms of hypothyroidism may be quite distinct, typical cretinism with idiocy does not appear to occur in such marked form as in European regions of endemic goiter[2] The evolution of the trypanosome in the insect host has been traced quite fully,[3] and there seems to be no doubt that in nature the bite of the conorhinus and possibly other insects is the regular mode of transmission of the disease, which, however, may be congenital In man and other vertebrates the trypanosome first lives in the blood, whence it passes into the tissues, practically no organ being spared, the flagella and undulating membrane being lost, and a rounded form not unlike that of the leishmania assumed Intercellular and intracellular agglomerations of small rounded bodies are found which, when liberated, may assume the typical trypanosome form The skeletal muscles seem to be the seat of choice, then the adipose and connective tissue, the heart muscle, lymph nodes, etc The parasite may multiply in muscle tissue without causing a definite reaction In man the serous membranes, especially the peritoneum and pericardium, have been found greatly increased in thickness, and the lymph nodes, liver, spleen and heart enlarged There may be marked parasitic and cellular infiltration and other changes in the heart muscle and in the brain, especially in the acute form, may be multiple parasitic foci with invasion of the neurocytes The thyroid is enlarged regularly, with infiltrations and fibrous changes, and, as stated, the effects of disturbed thyroid function are seen in the clinical picture.

Whether morbid conditions associated with goiter, occurring in other parts of the world, are of the same or similar nature as this interesting Brazilian disease we have yet to learn.

PHILOLOGY AND PATHOLOGY

Sometimes the man of letters who, in criticizing the follies of others, ventures out of his field, presents a spectacle quite as amusing as any which he satirizes. In a recent book "On the Art of Writing," by Sir Arthur Quiller-Couch, occurs some animated comment on that useful, if hybrid, word "antibody." Sir Arthur's sprightly English is worth quoting:

> But I have another word for our men of science. It was inevitable, perhaps, that Latin—so long the universal language—should cease in time to be that in which scientific works were written. It was impossible, perhaps, to substitute, by consent, some equally neat and austere modern language, such as French. But when it became an accepted custom for each nation to use its own language in scientific treatises, it certainly was not foreseen that men of science would soon be making discoveries at a rate which left their skill in words outstripped; that having to invent their terms as they went along, yet being careless and contemptuous of a science in which they have no training, they would bombast out our dictionaries with monstrously invented words that not only would have made Quintilian stare and gasp, but would affront the decently literate of any age.
>
> After all and though we must sigh and acquiesce in the building of Babel, we have some right to examine the bricks. I was waiting, the other day, in a doctor's anteroom, and picked up one of those books—it was a work on pathology—so thoughtfully left lying in such places, to persuade us no doubt, to bear the ills we have rather than fly to others capable of being illustrated. I found myself engaged in following the antics of certain bacilli generically described as 'antibodies.' I do not accuse the author (who seemed to be a learned man) of having invented this abominable term; apparently it passed current among physiologists and he had accepted it for honest coin. I found it later on, in Webster's invaluable dictionary: etymology, 'body' (yours or mine) 'anti' up against it, compound, "antibody,' a noxious microbe.
>
> Now I do not doubt the creature thus named to be a poisonous little wretch. Those who know him may even agree that no word is too bad for him. But I am not thinking of *him*. I am thinking of *us*; and I say that for our own self-respect, whilst we retain any sense of intellectual pedigree, 'antibody" is no word to throw even at a bacillus. The man who eats peas with his knife can at least claim a historical throwback to the days when forks had but two prongs and the spoons had been removed with the soup. But "antibody" has no such respectable derivation. It is, in fact, a barbarism, and a mongrel at that. The man who uses it debases the currency of learning; and I suggest to you that it is one of the many functions of a great University to maintain the standard of that currency, to guard the *jus et norma loquendi*; to protect us from such hasty fellows or, rather, to suppeditate them in their haste.

We have no wish to dwell on the novel conception of antibody here advanced for the delectation of pathologists, and shall only express the hope that some day Sir Arthur will push his researches a little farther than Webster's dictionary. It is impossible to refrain, however, from drawing attention to the implication presented by another mongrel word which pops out with delightful spontaneity in the easy flow of Sir Arthur's gentle diatribe. When he chanced on the debased and barbaric word "antibody" he was waiting, he says, "in a doctor's anteroom." Meticulous pedants may be pardoned for wondering why a "sense of intellectual pedigree" is not offended by the use of the word "anteroom," but is revolted by "antibody."

In point of fact, the novelty in a language has always to fight its way into good society. Once its position is made good it is accepted by writers of high and low degree, often, indeed, with touching unconcern, by the very persons who would preserve the "purity" of a language against newcomers of exactly similar lineage. Whatever be the case with respect to precise scientific nomenclature, which some believe stands on a different footing, there is no doubt that our ordinary language grows through additions based on usage and not according to strict rules of procedure. The hybrid may claim a right to live equally with the mutant.

Current Comment

THE FUNCTION OF THE PROSTATE

The student of medicine who searches for physiologic wisdom in regard to the functions of the prostate will be sorely disappointed. Structurally the prostate consists of glandular, connective and nonstriated muscular tissues. The latter are said to be arranged both longitudinally and circularly in relation to the glandular tissue, and the organ also is supplied with numerous nerve cells. Among the conjectures made in reference to this anatomically complex and therefore presumably physiologically active outfit has been the hypothesis that as a muscular structure the prostate possesses the properties of a sphincter for the bladder. This has been denied on the basis of available experimental evidence by G. Walker.[1] He believed that the prostatic musculature has as its prime function the discharge of the secretion prepared in the glandular portions. Marshall's[2] more recent review of the behavior of the prostate indicates that its musculature contracts during ejaculation, thus forcing its own secretions into the urethra and aiding in propelling the seminal fluid along this portion of the urogenital tract. The nature of the contractions, whether tonic or rhythmic, has not been indicated. J. A. Waddell[3] has contributed some facts regarding the innervation of the prostate and its consequent response to certain drugs. In the latter respect it resembles the vas deferens[4] and the seminal vesicle[5] Like other portions of the internal generative tract which have been examined, the prostate possesses a motor parasympathetic as well as a motor sympathetic innervation The problem of the real function of the prostatic secretion itself is left unsolved It has been noted that the spermatozoa are practically motionless while in the seminiferous tubules of the testis, but become actively motile in the vas deferens, or when mixed with prostatic secretion This observation, however, is far from solving the questions at issue, especially since removal of the prostate and seminal vesicles in animals seems to prevent the possibility of fertilizing, although the testes remain apparently intact[6]

SOME ASPECTS OF PLACENTAL FUNCTION

A century and a half have elapsed since John Hunter or his brother William Hunter—or, if it serve truth better, both of these—discovered the real nature of the connection between the mother and the fetus, thereby laying the foundation for our present knowledge of the structure of the placenta There is no direct channel of communication between fetal and maternal circulation The placenta represents the fetal organ for respiration, nutrition and excretion As to the nature of the exchanges which go on between the two related organisms and the mechanisms involved in the transference, practically nothing is known The structure of the parts concerned favors an interchange of products between the mother and the fetus An extensive vascular bed, chiefly secured by division of the large fetal vessels into a myriad of smaller ones, is further enlarged by the arrangement of the smallest of these, they form loops which hang toward the maternal blood The vascular loops surrounded by connective tissue, which, in turn, is covered by epithelium, constitute the chorionic villi These tiny, finger-like projections are immersed in lakes of maternal blood They act both as receptors of nutriment for the fetus and as its excretory agents Beyond these facts, we are told by Slemons and Morriss, from whom the foregoing description is borrowed, knowledge of the physiology of the villi is fragmentary How substances pass from one circulation to the other through the layers of the chorionic connective tissue and epithelium—which, together with the wall of the fetal vessels, constitute the placental partition—is a question which is answered thus far only hypothetically It has been assumed that the placenta takes some undefined sort of active participation in the preparation of the fetal nutriment In this "vitalistic" conception, placental enzymes have recently been made to play a part, as is so often the case when physiologic obscurity necessitates so vague a hypothesis The supporters of the "mechanistic" theory of placental function, on the other hand, believe that the placenta behaves essentially as a permeable membrane Slemons and Morriss have studied the comparative chemical composition of fetal and maternal blood As nearly as possible the specimens were obtained simultaneously, just after birth occurred In a considerable number of normal obstetric patients the average rest-nitrogen was found to be 25 mg per hundred c c in both maternal and fetal bloods, the urea-nitrogen was likewise essentially the same in the two circulating fluids This identity of content, particularly in the case of urea, indicates conclusively that this substance passes through the placenta by diffusion Complications accompanied by an increase of urea in the maternal blood—toxemias of pregnancy, syphilis, decompensated heart lesions, and others—were also attended with a corresponding increase in the fetal blood-urea This novel finding in pathologic cases clearly confirms the diffusibility of urea through the placenta Whether or not there is an equally ready transfer of all the other soluble blood constituents, commonly included under the term rest-nitrogen of the blood, needs to be ascertained for each of the individual substances concerned A ready equalization on each side of the placental partition seems more than probable, however, in the light of these new blood analyses

THE FATE OF TRYPSIN IN THE STOMACH

The proteolytic enzyme of the pancreatic secretion has long been regarded as exceedingly sensitive to acids In the presence of even low concentrations of acids, the tryptic power seems to be permanently diminished or completely lost Many believe that gastric juice is peculiarly destructive to the proteolytic pancreatic ferment by virtue of the action of pepsin on the enzyme There is a practical aspect to this On the one hand it concerns the possible survival of tryptic power when intestinal contents are regurgitated into the stomach, as occasionally happens On the other hand, the futility of administering trypsin preparations by way of the mouth must be gaged in part by the fate of the enzyme in its contact with the gastric contents Judging by experiments which Long and Hull[1] have conducted in vitro, it appears that the common proteolytic enzyme of the pancreas, isolated as trypsin, is capable of withstanding a rather long digestion in presence of hydrochloric acid and pepsin, provided sufficient protein of some form is present to combine with all or part of the acid and so bring the hydrogen-ion concentration down to a certain level They[2] have now corroborated these findings by a study of what happens in the living stomach of animals under conditions which might well obtain in the human stomach at times when trypsin is ingested Long and Hull report new experiments in which the secretion of pepsin and acid was abundant, and from this point of view the conditions for the persistence of trypsin were not favorable Yet, in the larger number of experiments, the latter ferment was not destroyed by the other combination when sufficient protein was present to bring the concentration of the free acid down to a certain value Trypsin seemed to be destroyed or greatly weakened only when the acid was in excess with pepsin From these observations it appears, further, that possibly some tryptic digestion may occur even within the stomach when the free acid is low from protein combinations, and the destruction or weakening of the trypsin is a function, probably, of the hydrogen-ion concentration The trypsins employed in these experiments were relatively strong products It is not to be concluded that these results even remotely suggest that the administration of a few grains of the various commercial products claimed to contain trypsin or pancreatin would have any therapeutic significance In the dosages employed, such preparations are, as has been shown elsewhere, too weak to have any appreciable action

FOOD SUPPLY AND GROWTH OF POPULATION

The bodily welfare of man is dependent in large degree on a satisfactory solution of the problems of food, clothing and shelter With the rapid growth of population the need of suitable nutrients increases at a corresponding rate Economic foresight accordingly leads the critical observer of the increasing number of persons who demand sustenance to inquire whether the sources of supply continue to be adequate and whether they are likely to keep pace with the demands of the expanding nation in the years to come Prophecies of impending crises have been made from time to time by serious minded scientists and economists One writer, basing his view on the contention that wheat is the most sustaining food grain of the Caucasian race, has ventured the belief that if prophecies based on population statistics are trustworthy, the crisis will be on us before the end of the century It must be remembered, however, that the acreage devoted to agriculture is still expanding and that conservation processes as well as other factors, such as improved transportation facilities and changing customs in diet, are helping to improve the outlook New food possibilities are frequently being brought within the range of present needs In 1900 the population of the United States was 76 millions, now it is estimated at over 100 millions — a growth of 33 per cent The latest report of the secretary of agriculture gives some indication of the extent to which the supply of a variety of food products has kept pace with the growing demand occasioned by this increment of population The total production of most items on the food supply lists, such as poultry, fish, cereals, potatoes, citrus fruits and orchard fruits, during the sixteen years in which 26 millions of persons were added to the numbers to be fed, shows no diminution per capita The sugar production is the only one showing a significant increase Meat and dairy products constitute 37 per cent of the average diet, fish 2 per cent, cereals 31 per cent, Irish and sweet potatoes 13 per cent, and other vegetables 8 per cent It is notable that, notwithstanding the rapid increase in population, the production per capita of the commodities indicated, with the exception of meats and dairy products, has remained approximately the same or has increased

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals education, public health etc)

CALIFORNIA

Tuberculosis Foes Meet—A joint conference of the San Francisco and California Associations for the Study and Prevention of Tuberculosis was held at the St Francis' Hotel San Francisco January 25 The following physicians were reelected members of the board of directors Drs Mariana Bertola, Walter B Coffey Attilio H Giannini Charles G Levison Harry M Sherman and William C Voorsanger, all of San Francisco

Intern Examination—The Civil Service Commission of the County of Los Angeles announces an open competitive examination for intern in the Los Angeles County Hospital, to be held March 2, at various places throughout the country Applicants must be at least 21 years of age, citizens of the United States and must make application on blank forms, which will be sent on request to the Los Angeles County Civil Service Commission There are eighteen positions to be filled in July, 1917 and ten in January 1918 The service is for eighteen months and the compensation includes full maintenance and uniform All successful candidates must be graduates of medical institutions of recognized standing

ILLINOIS

Tuberculosis Hospital for Springfield—St John's Hospital, Springfield will build a tuberculosis sanatorium to cost $500 000 It will be 6 miles east of Springfield on a site of 153 acres Work will be begun in March

Smallpox in Mining Camps—Over 100 cases of smallpox have been reported in mining camps at Tovy, Bulpitt, Kincaid and Jerseyville The situation is in charge of Dr Edwin B Godfrey state board of health epidemiologist

Library for Society—Sangamon County Medical Society has established a medical library in the lecture room of St John s Hospital, Springfield A number of medical books and magazines have been donated, and *it is hoped to open* the library in March

Chicago

Personal—Dr Jacob J Minke returned to Chicago, February 8, after eight months' service in a military hospital at Pardubitz, near Prague Bohemia

Dr Billings Convalescent—Dr Frank Billings, who has been ill with pneumonia at his home, has safely passed the crisis and is steadily improving

Women's Clinics—The Women's Medical Club of Chicago held clinics for women physicians of Illinois, February 12 to 16 February 14 a banquet was held at the college club rooms Clinics were held at various hospitals during the week

Scarlet Fever at University—February 8 two additional cases of scarlet fever were reported in the Delta Upsilon fraternity house at the University of Chicago Thirteen members of the fraternity were placed under quarantine and part of Hitchcock Hall was also quarantined

New Red Cross Unit—A new Red Cross unit was formed at St Luke s Hospital February 10, with Mrs Heaton Owsley as chairman The organization will be divided into two classes under the direction of Dr Lewis L McArthur, and will meet at St Luke s and Michael Reese hospitals

INDIANA

Fire at Hospital—Fire at West Baden, February 11, destroyed the hospital at the West Baden Hotel, with a loss of about $25,000 No lives *were lost*

County Hospital Opened—The Bartholomew County Hospital Columbus, built at a cost of $100,000, was opened, February 6 This is the first hospital to be built in the state under the law giving counties the right to erect public county hospitals on petition of the requisite number of tax payers

Personal—Dr J Rilus Eastman, Indianapolis, who has been chief surgeon in charge of a hospital in Vienna for several months will return about February 20 Dr Henry O Bruggemann, Fort Wayne who had expected to sail for Rotterdam, February 5, to take Dr Eastman's place, has given up the trip on account of the severance of diplomatic relations between the United States and Germany——Dr Robert C Johnson, Frankfort, has been appointed first lieutenant, M C, Ind N G, and assigned to Ambulance Company No 1, succeeding Dr Donald C McClelland, Lafayette resigned——Drs Julius E Hiatt, Edson K Westhafer and George H Smith, Newcastle, suffered a loss of their offices furniture and fixtures by fire, February 6——At the annual meeting of the Indiana Society for the Prevention of Tuberculosis held in South Bend, Dr Alfred Henry Indianapolis, was elected president and Dr Roscoe L Sensenich, South Bend, vice president

MARYLAND

Hospitals Offered to Government—The Eudowood Sanitarium at Towson and the General and Marine Hospital at Crisfield have been offered to the government in case of war

Personal—Dr Ernest H Gaither and Dr Dwight H Mohr Baltimore, have been appointed on the staff of the Franklin Square Hospital——Dr Howard A Kelly, Baltimore, who has been ill with pneumonia in Florida is recovering and will return to Baltimore within a few weeks

Infant Mortality—The Baby Welfare Association has issued a report showing the relative standing of the ten largest cities in the country with regard to the infant mortality rate The ten cities and the order in which they stand are St Louis New York Philadelphia Boston Cleveland, Pittsburgh, Chicago, Detroit, Buffalo and Baltimore the rate ranging per thousand from eighty-nine in St Louis to 118 in Baltimore While Baltimore stands tenth in actual infant mortality rate the city has made the largest reduction in the infantile death rate of any of the ten cities

NEW JERSEY

Site for Hospital Offered—Edward Seifert has offered 28 acres on the New Homestead Road to the Rockland County Tuberculosis Hospital

Smallpox at Railway Camp—Following a case of smallpox in a camp of the Erie Railway at Jersey City, 300 workmen, mostly Mexicans and negroes, were vaccinated, January 28

War on Mosquitoes—The New Jersey Mosquito Extermination Association has asked the legislature for $100 000 for the current year to pay for work done by the municipal authorities and salt marsh counties to rid the state of mosquitoes According to the New Jersey state entomologist, nearly 200 000 acres of marsh in Ocean, Burlington, Atlantic and Cape May counties remain to be drained

Personal—Dr Jacob C Price, director of the state department of health gave a luncheon in Trenton, January 11, to the chiefs of various departments, in honor of Dr Millard Knowlton, who has been in charge of the bureau of education and publicity since its beginning, and who has resigned to take up the study of public health at Harvard University——Capt Frank Y Neer Paterson, assigned to Fifth Infantry, has been promoted to major, succeeding Major Joseph V Bergin resigned——Lieutenant Craig, Ridgewood, has been promoted to captain

NEW YORK

New Laboratory Site—The state department of health has purchased a site for a new laboratory at Albany, at a cost of $40 000

State Society to Come to Utica—The Medical Society of the State of New York will meet at Utica, April 23 to 26 Headquarters will be at the state armory

Ambulance Company Officers Entertained—The officers of the Second Ambulance Company, which returned from the border a short time ago were entertained at dinner by the officers of the Rochester Base Hospital at the rooms of the Rochester Physicians' Association Dr John M Swan presided

Hospital Wanted for Westchester—Three hundred thousand dollars has been appropriated for a hospital at East View The present county hospital has accommodation for 110 patients, and during the last year there were at least 185 patients who needed hospital treatment The new hospital will cost $1,200,000, and will accommodate 600 patients

Reduction of Infant Mortality—In spite of a recent epidemic of infantile paralysis, the infant mortality rate for the state, outside of New York City, for 1916 was ninety-four per thousand, a reduction of six points from 1915 and of twenty points from 1911 There was also an actual reduction of 481 deaths of infants during the year The death rates from scarlet fever, typhoid fever, diphtheria and tuberculosis were the lowest in the history of the state

Personal—Dr Raymond Sanderson has resigned as director of the Ulster County Laboratory, Kingston, to accept the position of pathologist at Vassar Hospital, Poughkeepsie——Dr Franklin N Barrows has been appointed assistant health commissioner of Buffalo——Dr James Taylor Harrington has been appointed commissioner of health of Poughkeepsie, succeeding Dr Lewis H Marks, resigned——Dr John H Pryor has been elected president of the Buffalo Association for the Relief and Control of Tuberculosis

Compensation Cost—The State Industrial Commission states that the aggregate amount of compensation paid in New York state under the workmen's compensation law during 1916 was $11,500,000, which includes $5,000 000 for deaths, nearly $4 500,000 for permanent injuries and nearly $2,000,000 for temporary injuries This does not represent the total economic loss from accident and it does not include the cost of medical benefits the administration of the compensation law or the wages and medical loss of injured employees not covered by the compensation This would probably make the direct and indirect loss of the year amount to nearly $30 000 000

New York City

Harvey Society Lecture—The next of the series of Harvey Society Lectures will be given at the New York Academy of Medicine February 24 Prof John R Murlin of Cornell University will lecture on The Metabolism of Mother and Offspring Before and After Parturition '

Three Ambulances for City—The Militia of Mercy has presented to the city three ambulances, used since last September for transporting infantile paralysis victims from their homes to hospitals for after-treatment These ambulances cost $4 500 each, and have transported 5,000 patients since last September

New Tuberculosis Procedure—At a conference with Chief Justice McAdoo on the control of unruly consumptives Judge McAdoo suggests that unruly consumptives be brought before him for possible commitment to the custody of the department of corrections for disorderly conduct Hereafter this method will be adopted

Nasal Diphtheria Prevalent—An unusual number of cases of nasal diphtheria have been brought to the attention of the department of health by the physicians of Willard Parker Hospital The disease runs a mild course and resembles an ordinary rhinitis Physicians are urged to be on the lookout and to send cultures of rhinitis in infants to the department laboratory for diagnosis

Conference on Hospital Social Service—The seventeenth meeting of the New York Conference on Hospital Social Service was held at the New York Academy of Medicine February 7 The topic of the evening was "Children" Papers were presented by Dr Henry D Chapin on Preventive Care of Children' , by Dr Charles R Conklin on "Preventive Work for Children,' and by Dr Frederick L Brush on "Home Convalescence '

Increased Death Rate—During the week ending February 3, there were 200 deaths more than in the corresponding week of 1916 Of the 1 754 persons who died in the city, 239 deaths were from lobar pneumonia 121 from bronchial pneumonia forty from influenza and twenty-one from bronchitis, a total of 421 deaths from respiratory diseases The death rate for the week was 15 95 per thousand, which compares unfavorably with 14 41, the rate for the corresponding week of 1916

Examination for Oculist—The Municipal Civil Service Commission will receive at the Municipal Building up to February 23, applications for the position of oculist, grade two Applicants must be between 21 and 45 years of age, and must present a license to practice medicine in the state of New York, and evidence of at least one year of internship or three years' service in the outpatient department of a hospital giving special training in diseases of the eye Duties are supervision and responsibility for the diagnosis and treatment of diseases, physical abnormalities and other conditions of the eyes in the City Hospital Clinic or other institutions Compensation varies from $1,030 to $1 380 a year Oculists are usually required to work twenty-one hours a week in the department of health

OKLAHOMA

Personal—Dr Benjamin S Gardner, Marietta, fell from a porch at his home recently, dislocating his hip——Dr Joseph W Bone, Sapulpa, who has been ill for several months, is reported convalescent

OREGON

Date Fixed for State Meeting—The next annual meeting of the Oregon State Medical Association will be held in Portland, June 28 to 30

State Board Asks Larger Staff—The state board of health in its report asks for a school nurse for the inspection of schoolchildren and the supervision of school sanitation, an epidemiologist as deputy health officer, and a field representative for public educational work

Personal—Dr Harry F McCay, Portland, has been appointed county physician of Multnomah County, to succeed Dr E P Geary——Dr Spiro Sargentich, Portland was the guest at a dinner given by fifty physicians of the city recently, at which he detailed some of his experiences as a surgeon in the Serbian army

PENNSYLVANIA

To Disinfect School Pencils—A bill introduced into the senate February 7, provides for the daily disinfection of all pencils and penholders used by the school pupils

Typhoid Fever—Dr Howard Hull of the state department of health, Harrisburg, is investigating the typhoid epidemic in Rush Township, Center County, where he found eighty-eight cases instead of the thirty-five originally reported by the health board It is planned to open a temporary hospital at Osceola Mills, in the infected territory

Economic Topics Discussed—The Lehigh Valley Medical Association met in Palmerton, February 1 Dr John W Luther, chief surgeon of the New Jersey Zinc Company, Palmerton, spoke on "The Physical Examination of Employees", Major Robert U Patterson, M C, U S Army, director of the Bureau Service of the American Red Cross, on "The Relation of the Red Cross to Civilian Physicians and the Military Service," and Dr Francis D Patterson, Harrisburg, chief of the Division of Industrial Hygiene and Engineering of the Department of Labor and Industry, on "The Relation of the Physician to Some of the Problems of Modern Industry"

Personal—Dr Henry A Gorman, first assistant physician at Mont Alto Sanatorium for five years, was elected senior resident physician of the Harrisburg Hospital January 29——The residence and office of Dr Willet E Hughes, Ashley, were damaged by fire to the extent of $4,500, January 30——Dr William C White, medical director of the Tuberculosis League Hospital, Pittsburgh, has accepted an invitation to go to France and assist in restoring the health of French soldiers who have returned from the front suffering from pulmonary tuberculosis——Dr Robert M Patterson, Beaver Falls is recovering from an operation for appendicitis——Dr Robert H Jeffrey, Uledi, has been appointed director of the safety department of the W J Rainey Company, Uniontown to succeed Dr Samuel A Baltz, resigned

Philadelphia

Memorial to White—In memory of the late Dr William White, his widow has presented a motor ambulance to the American Ambulance corps on the western war front

New Field Hospital Established—Dr Eugene Swayne at a meeting held January 18 organized a new field hospital company to be known as Field Hospital Company No 3, N G Pa

New Officers—The newly elected officers of the Philadelphia Pediatric Society are president, Dr John F Sinclair, vice president, Dr William Duffield Robinson, secretary, Dr A Graeme Mitchell and treasurer, Dr Charles V Dorwarth——Section of Ophthalmology of the College of Physicians Dr William T Shoemaker, chairman, and Dr J Milton Griscom, clerk

Alumni Day—Alumni Day will be celebrated at the University of Pennsylvania, February 21, with a luncheon in Houston Hall, an alumni meeting at which information about the medical merger will be given, and a dinner by the provost to visiting alumni in the evening February 22, the exercises of University Day will be held at the Academy of Music The address will be delivered by President Jacob Gould Shurman of Cornell University

Personal—Dr L Webster Fox has been reelected president of the Pennsylvania Home Teaching Society and Free Circulating Library for the Blind——Dr Francis Abbott has returned to the war zone in France——Dr Hugh B O'Donnell was injured, January 19, in a collision between his automobile and a trolley car——Dr Horace Phillips has been appointed visiting physician in the psychopathic ward of the Philadelphia Hospital succeeding Dr Albert C Buckley, resigned——Dr David N Husik has been appointed laryngologist and otologist to the Philadelphia General Hospital succeeding Dr Charles P Grayson, resigned

CANADA

Personals—Col Herbert A Bruce, Toronto, was tendered a complimentary banquet by many medical friends in Toronto, February 14——Capt Robert J Wilson, Toronto, is home from the Ontario Military Hospital England having come out as medical officer with a party of wounded soldiers——Col John Taylor Fotheringham, Toronto, has been made a C M G

University News—At the McGill annual class dinner it was announced that 1 800 graduates of McGill were serving abroad, that 132 had been killed and 163 wounded One of the fellows of the medical faculty has received the V C four the D S O one the C M G, one the Order of the Bath and seven have been mentioned in dispatches The forty three graduates of the class of 1917 have volunteered in a body

Insanity in Quebec Increasing—The annual report of the Verdun Hospital for the Insane shows that at the close of 1916 there were 766 patients as inmates, an increase of forty over 1915 The 1916 figures comprise 382 men and 384 women Twenty returned soldiers were admitted during the year, of whom thirteen were being treated at the close of the year The total number of patients undergoing treatment throughout the year was 962, as against 911 in 1915 Dr Burgess, the superintendent stated that the principal causes of insanity were mental anxiety due to family afflictions business worries disappointments, etc Drink and drugs came a poor second while senility heredity and vice filled up the rest of the list During 1916 131 patients had been discharged and there were sixty-one deaths, general paresis leading as the cause of death

GENERAL

Sioux Valley Medical Association Meeting—The Sioux Valley Medical Association will hold its next annual meeting at Sioux Falls S D, in June

Red Cross Base Hospital at Milwaukee—The Milwaukee Chapter of the American Red Cross has raised $30 000 for a base hospital of which Dr John L Yates will be in charge

Indian Service News—Dr Joseph A Murphy, medical supervisor, has resigned——Dr Robert W Bell of the San Juan Reservation, N M, has been placed on the active list, M R C, U S Army

New Journal of Endocrinology—The first issue of a quarterly to be known as *Endocrinology The Bulletin of the Association for the Study of Internal Secretions* has just appeared It is edited and published by the secretary at Glendale, Calif

Railway Surgeons to Meet—The tenth annual meeting of the Association of Surgeons of the Illinois Central and the Yazoo and Mississippi Valley Railroad companies will be held in New Orleans, March 30 and 31, with headquarters at the Hotel Grunewald

McIntire Prize—The American Academy of Medicine announces two prizes from the McIntyre fund, one to be awarded in 1918 and the other in 1921 The subject for 1918 is "The Principles Governing Physicians' Compensation in the Various Forms of Social Insurance" The committee to award this prize consists of Drs John L Heffron, Syracuse N Y, Reuben Peterson Ann Arbor, Mich and John Staige Davis Richmond, Va The subject for 1921 is "What Effect Has Child Labor on the Growth of the Body?" The committee consists of Drs Thomas S Arbuthnot, Pittsburgh, Winfield Scott Hall Chicago, and James C Wilson, Philadelphia The prize for 1918 will amount to $100, and in 1921 to $250 Detailed terms governing the competition may be secured from the secretary of the academy

Bequests and Donations—The following bequests and donations have recently been announced

Presbyterian Hospital, Philadelphia, $5 000, to maintain a bed for the members of the Harriet Holland Memorial Church Sunday School by the will of Ella B Morris

The John S Billings Memorial Fund, for the purchasing of books for the New York Public Library and the Anna Palmer Draper Fund $450 000 Polyclinic Hospital New York, $47 767, Children s Aid Society New York Association for Improving the Condition of the Poor New York Skin and Cancer Hospital, and Laboratory of Surgical Research of the New York University each $23,883, by the will of Mrs Mary Palmer Draper

New York Association for Improving the Condition of the Poor and New York Association for the Blind, each $10 000 by the will of Mrs F T Lord

Postgraduate Hospital New York $2 000 the proceeds of a sale and entertainment for the benefit of the Babies Ward

FOREIGN

Psychopathic Prize—The late Dr Valentin Magnan, formerly president of the Paris Academy of Medicine, has bequeathed to that organization the sum of $5,000 the income of which is to be awarded triennially to the author of the best work on a psychopathic subject

Swiss Neurologic Journal—The Swiss Neurologic Association at its recent annual meeting voted to found with the Alienist Association a journal to be the official organ of the two societies and publish their transactions and original articles

From Cuba—Dr R Menocal, professor of clinical surgery and skin diseases at the University of Havana, has been appointed secretary of the national public health service, better known as the "Sanidad y Beneficiencia" The profession in Cuba tendered him a banquet on the occasion He takes the place left vacant by the death of Dr Enrique Nuñez Prof F Dominguez Roldan was appointed dean of the medical faculty in place of Menocal

Deaths in the Profession Abroad—E Cervera, one of the leading surgeons in Spain director of the Instituto Rubio since the death of Rubio, aged 61 He is said to have been the model of a good physician who was at the same time a most skilful operator He founded a department at the institute for research on cancer and published a number of works on abdominal and nerve surgery, and on the gastro-duodeno-hepatic associations of pancreatic disease

Cooperation with International Health Board—The president of the state of Rio de Janeiro according to W C Downs commercial attache at Rio (*Commerce Reports*, February 8), has been given authority to facilitate the mission of the International Health Board by decreeing sanitary measures, taking the necessary steps to obtain the aid of municipal councils and meeting necessary expenses by opening the required credit A decree covering these points will be submitted to the legislative assembly at its first regular meeting for definite approval

Presentation of Bloch's Portrait—An oil portrait of Prof O T Bloch was hung recently with appropriate ceremonies in the hall of the Surgical Academy at Copenhagen in preparation for his approaching seventieth birthday The surplus left from the subscriptions for the portrait was presented to him and he turned it over to the building fund of the medical society He was for a long time on the editorial staff of the *Hospitalstidende* and has published numerous works in this and in Scandinavian British and French surgical journals He has also published several books, including one on the history of treatment of wounds from the earliest to modern times

Association of Medical School Inspectors in the Netherlands—Replies to a questionnaire sent out to the members of the Netherlands Vereeniging van Schoolartsen show that the advice of medical inspectors is seldom sought when a new schoolhouse is contemplated, and still more rarely is it heeded In three new schoolbuildings the schoolrooms are on the north and the locker rooms take up the south exposure In others the playgrounds are to the north of the building At the recent annual meeting a number of speakers emphasized the importance of open-air schools in the fight against tuberculosis They complete the cure for children who have taken a course of treatment in a sanatorium The ferry boat open-air schools of New York were commended The fact that some other member of the family has or has had tuberculosis should entitle a child to admission into the open-air school, but 'open" and surgical tuberculous patients belong in institutions The association, in connection with the association of language teachers, voted to found a special journal

Inconsistencies of Recent French Legislation on Taxation of Pharmaceuticals—G Linossier comments in the *Paris medical* on a recent law imposing a tax on pharmaceutic specialties A tax is imposed on pharmaceutic specialties of which the formula is not published and which an older law prohibited from being sold Officials are in a quandary, as infractions of the old law have been overlooked to an extent impossible under the new law Pharmacy inspectors find it difficult to forbid the sale of remedies on which the state has already collected a revenue tax The restriction of the tax to pharmaceuticals with secret formulas hits French manufacturers in particular as most French pharmaceuticals are merely combinations of known drugs put up in an attractive way under a fancy name The owners do not like to publish the formulas, as any one could then make them up German pharmaceuticals are mostly new synthetics, the composition of which is known and which are exempt under the new law Linossier admits that the legislators had no intention of favoring German pharmaceuticals but blundered merely from ignorance, and asks whether or not it is the proper thing to entrust such matters to incompetents

Foreign Exchanges in 1916—The first week in February brought an unusually large batch of European medical journals The mail included the December numbers making the volumes for 1916 complete for those received during the year With the exception of Germany until last week weekly exchanges have arrived as regularly as in the years before the war They have come unfailingly from England France, Holland, Italy Russia the Scandinavian countries Spain and Switzerland The monthlies in some of the countries have taken two years to complete their 1915 volumes, but they are now complete and are starting on their 1917 volumes The Swiss *Correspondenz-Blatt* announced that it had skipped the November and December issues on account of a labor strike The issue of the Netherlands weekly for July 29 failed to arrive, and also No 2 of the big quarterly issued by the Swedish Medical Association With these exceptions the file is complete for twelve exchanges from France, with three others not quite complete yet, one complete each from the Netherlands, Finland, Russia and Spain, three from Italy, three from Japan, seven from the Scandinavian countries and two from Switzerland A few other journals from various countries show several gaps Besides the above, the four journals from the leading South American states have arrived with a regularity unknown until 1915 Only about half of the issues of the five big German weeklies were received during 1916 They have been published abstracts from the missing numbers have appeared occasionally in the Holland and Scandinavian journals The *Zentralblatts* stopped coming in November 1915, and only one lone *Zentralblatt* arrived in 1916 The above includes merely the journals in foreign languages that it has been the custom to review regularly in the current literature department

WAR NOTES

Praise for Wisconsin Surgeon—A surgical unit sent to Austria last summer in charge of Dr John R McDill, Milwaukee, has received high praise for efficiency from Prof von Eiselsberg, in charge of Austrian military hospitals

American Surgeons Abroad—Drs Carl Edwin Allison, Somerville Mass James V Ricci, Providence, R I, Jerome F Potts, Washington D C, William M Findley, New York, Frederick A Simmons Wakefield, Mass, J Franklin Harvey, Boston, Charles Curtis Allen, Topeka, Kan, Leo Thomas Kewer, Waverley Mass, Charles F Gormly, Providence R I, William H Mackay, Worcester, Mass, Audley O Sanders, Boston Stanley Bridges Worcester, Mass, and Guy Watt, Worcester sailed from New York, February 10, for service in the British hospitals on the western front

PARIS LETTER

Paris, Jan 18 1917

The War

IMPROVEMENT IN THE ORGANIZATION OF THE MILITARY SURGICAL SERVICE

The undersecretary of state of the military health service has adopted various noteworthy measures of organizing the surgical service of the army For instance, a consulting surgeon has been appointed for each army corps Surgical squads have been formed to assist at the base hospitals whenever there has been a great deal of work Each of these squads consists of a surgeon and his usual aids assistant surgeon, anesthetist and trained assistants This combination accomplishes results far superior to those obtained heretofore by isolated surgeons who had to work with untrained help picked at random

INTER-ALLY CONFERENCE FOR THE STUDY OF PROFESSIONAL REEDUCATION

As stated in a previous letter, this conference will be held in Paris March 6 at the initiative of the Belgian government supported by the French government The program of this conference will be as follows First section—Physical reeducation (*a*) physiotherapy and medical gymnastics, (*b*) prosthetic apparatus, (*c*) professional work Second Section—Professional reeducation (*a*) aspect of professional life, (*b*) When shall professional reeducation begin? Of what shall it consist? (1) Intellectual and (2) manual departments, (*c*) mechanical aids working arms, orthopedic appliances and special equipment for the use of invalids, (*d*) organization of schools large general schools, small special schools methods of teaching, utilization existing institutions and facilities Third Section—The placing and adaptation of invalids (*a*) in agriculture and the minor industries and business, (*b*) in industry war industries and others, (*c*) relation of the able bodied and invalids in shops as to salaries and division of work, etc Fourth Section—Economical and social interests of invalids (*a*) obligatory reeducation, (*b*) reeducation after the war of men who were unable to take advantage of this service during the hostilities, (*c*) absolute invalids, (*d*) permanent protection of the mutilated and crippled, mutual societies cooperative societies official organizations and private institutions Fifth Section—The blind the deaf, etc (*a*) their reeducation, (*b*) their placing, (*c*) their economic and social interests

VALUE OF NERVE SUTURE IN WAR SURGERY

Drs Chiray and E Roger reported to the Societe medicale des hopitaux de Paris on cases of nerve suture They insist that in order to draw valuable conclusions it is necessary to classify the observations carefully and to base them only on cases of nerve suture after complete section Chiray and Roger found that nerve suture is followed by negative results in 29 per cent of the cases, sensory response to electric stimulation, without motor response, occurs in 48 per cent and motor and sensory restoration occurs in 23 per cent Return of sensation always precedes return of motion Motion returns in the radial nerve after five months, in the ulnar after eight months, in the median after seven months, in the sciatic and popliteal after from two to five months The radial sciatic and external popliteal nerves seem to give the best results Experience has shown that early operation is the most effective, nevertheless, operations performed at the fourth or the sixth month are often successful Chiray and Roger emphasize the importance of total resection of all fibrous tissue coaptation of the severed ends without tension and without bruising The particular method of operation does not seem to have any decisive bearing on the result End-to end suture and nerve grafting give equally good results Chiray and Roger are convinced of the importance of postoperative treatment particularly the use of a prosthesis and of the local ionization of potassium iodid Dr Albert Frouin, who has done considerable research work on the suture of nerves after complete section reported to the Societe de biologie the results he obtained He makes an immediate suture using silk floss instead of catgut for suture material and the finest needles obtainable so that he can suture the perineurium without injuring the axis cylinders Seventeen animals operated on in this manner walked very well on the soles of their feet after fifteen days

CULTURE OF MEDICINAL PLANTS

M de Poumeyrol recently presented to the general syndicate of the French drug trade a report on the harvest and culture of medicinal plants in France The war has caused a considerable decrease in importation of these products which come almost exclusively from other countries and it is necessary to take steps to remedy this *state of affairs* Russia has created a special section in her agricultural department, and has distributed to farmers seeds amounting in value to 9 000,000 rubles She has also appropriated premiums and arranged for loans to those who will cultivate these plants M de Poumeyrol s report requests that tests be made in agricultural and rural schools, that a manual be placed in the hands of those who would like to engage in this culture, that the necessary advice be given to those who want to cultivate medicinal plants now growing in a wild state, and that measures be taken by transportation companies to modify the tariff on these articles, which is already too high

POISONING BY EXHAUST GASES IN AUTOMOBILE AMBULANCES

Dr Tanon called the attention of the Reunion medicochirurgicale de la V e Armee to the danger of heating auto ambulances from the exhaust pipe when the motor is not working right and the joints are not sealed hermetically Fumes are discharged into the interior of the car These fumes are noxious In some cases they have caused fatal results Although the quantity of carbon monoxid contained in the gases is small the lesions observed at the necropsy are those of carbon monoxid poisoning The products of incomplete combustion do not cause death in the animal They do not destroy the red blood cells nor do they reduce the hemoglobin Blood impregnated with carbon monoxid is capable of reabsorbing oxygen but greater activity of the respiratory apparatus and the respiratory center is required The first symptoms experienced appear to be the result of a toxic action on the respiratory center Physicians at base hospitals should instruct the chauffeurs as to the dangers of exhaust heating systems Every conveyance heated in this manner should be inspected regularly and often, and repaired as soon as even a trace of gas is detected

LONDON LETTER

London, Jan 22, 1917

Sanaphos versus Sanatogen a Comedy of Quackery

The vicissitudes of the German nostrum Sanatogen since the beginning of the war, have been described in previous letters They are not yet ended, and may be described as a comedy in three acts

Act I Taking advantage of the animosity against everything German, a British company starts a new nostrum under the name of Sanaphos and with the usual blatant boastfulness, proclaims it a soverign remedv and an improvement on Sanatogen

Act II The government sells the assets of Sanatogen to a British company (The Journal, Dec 16, 1916 p 1861) which announces that 'the business will be conducted on those thorough scientific lines which have in the past given the Germans almost a monopoly in the production of skilful organic compounds" Many physicians" it was also stated 'informed us that they were disappointed with the effects of the numerous imitations of Sanatogen"

Act III The wrath of the Sanaphos people has been aroused by this move and they have sent to physicians the following circular letter as a rejoinder

> In accordance with the strange policy adopted by our Government in connection with Enemy concerns the German owner of Sanatogen has been allowed to capitalise his good will [This is only another way of saying that the government has sold the good will and the question what will be done with the proceeds remains for settlement after the war The object of course, is to make capital out of the anti German feeling of the country] Presumably the proceeds and the accumulated profits collected for him by the State will be held for his benefit at the end of the War The new owners have in connection with their advertising scheme thought it right to attack their British competitors We desire to make it clear that Sanaphos is not and never was an imitation of Sanatogen but it is what it professed to be viz an improvement on Sanatogen as is proved by the *following* scientific statement Considerable light has recently been thrown on the *etiology* of deficiency diseases and you will agree that nervous disorders come within this category Healthy nutrition is the *only* restorative in such cases and that is why the nerve food Sanaphos is so remarkably *successful* It does not supply mere constituents like casein and *phosphorus* compounds but contains also the vitalising and activating entities vitamines and enzymes *In other* words it is not a moribund chemical combination of casein and phosphates, but provides *in addition* the quickening nourishing qualities characteristic of fresh uncooked milk due to unde stroyed vital constituents *Sanaphos* is *therefore* paramount in the treatment of deficiency diseases and its *powerful* restorative effects as a nerve food and general reparative is thus accounted for by well established physiological facts It is unique also in being soluble pre senting its constituents when mixed with *water* exactly in the same condition as milk and is further reinforced with easily appropriated organic phosphorus compounds

Investigation of Cerebrospinal Fever

In the first year of the war outbreaks of cerebrospinal fever occurred among the newly enlisted young soldiers in several of the camps scattered throughout England The director-general of the Army Medical Service at once arranged for an investigation of the disease by the Medical

Research Committee (a body appointed under the insurance act for the purpose of organizing medical researches) A central laboratory and thirty-seven district laboratories were equipped

The report of the committee, which has just been published is most important It was found by agglutination tests that there were four different types of meningococci From these a serum was prepared for the treatment of the disease It was found that 1 A case of cerebrospinal fever yields only a simple type of meningococcus from the cerebrospinal fluid, that is, a case is always strictly one type or another 2 The type found in the nose is always the same as the type in the brain 3 The germ is always present in the nose at the beginning of the attack, therefore every case of the disease is an instance of a "carrier" becoming a victim to his own carried infection 4 Finally, "type breeds true' in every case, the types are not interchangeable As soon as a case is diagnosed serum is administered Swabs are taken from the nose and from all contacts The energy with which this is done is shown by the fact that in the case of an outbreak in a large garrison, a large section amounting to 10 000 men, the vast majority of whom had not been in contact with patients, were swabbed and 400 of these were isolated until they became free from organisms The results of treatment indicate great improvement, thus out of thirty-three military cases treated in the London district alone last season by serum prepared under these methods, only three patients died, a result in marked contrast with the 40 to 60 per cent mortality usually found before this serum was available

The Suppression of Quacks

Lord Rhondda (president of the Local Government Board) received a deputation yesterday from a number of local authorities and medical bodies who submitted their reasons for urging that unqualified practitioners should be prevented from undertaking the treatment of venereal diseases The lord mayor of Birmingham expressed the opinion that public money should not be spent unless the best results could be obtained, and that the work should not be minimized by unqualified persons being allowed to treat venereal cases These diseases, to be perfectly treated, should be taken in hand in the early stages, and in order to protect the work of the local authorities quack advertisements should be suppressed, and unqualified persons prevented from treating the patients Dr Frederick Taylor, president of the College of Physicians, said that theoretically all diseases should be treated by those who knew how to deal with them and for that reason the Royal College of Physicians asked that unqualified persons should be stopped

Lord Rhondda, in reply to the members of the deputation said that his department fully realized the burning nature of the great question We had to consider not only the health of the present population but also the health of future generations, and the need of bringing up a healthy race Of all the matters which came before him he looked on this as one of the most urgent and important questions which his department had to deal with in the near future Having taken that view and having put their hands to the plow, there would be no turning back He thought he could give them that assurance He wished to thank the Royal Commission on Venereal Diseases for the work it had done He thought it was largely due to the commission that the country today was so impressed with the urgency of the matter They would not expect him to commit the government definitely that day to any particular form of legislation, but he thought he could give them the assurance that legislation would be required, and that it would probably be brought in He was perfectly satisfied that physicians were actuated by considerations of state policy and not self-interest

Restriction of the Production of Alcoholic Drinks

The government has issued an order reducing the quantity of beer to be brewed from April 1 to 70 per cent of the output of the preceding year This means a reduction to one half of that of the year preceding the war There is to be a corresponding restriction in the release of wine and spirits in bond

The food controller, Lord Devonport, states that these steps are in no way to be deemed measures of temperance or social reform The barley, sugar and other ingredients used in brewing are required for food It is a question of bread versus beer In the year preceding the war ending March 31, 1914, the quantity of beer brewed amounted to 36 000,000 standard barrels The production of beer will be restricted by the new order to 18 200,000 standard barrels The food side of the reduction is represented by 286,000 tons of barley, 36,000 tons of sugar and 16,500 tons of grits, also a brewing ingredient On the transport side there will be, first of all, a large saving in mercantile marine tonnage, and further, a considerable saving in land transport, such as railway and other forms of haulage There will also be a consequent reduction in the amount of labor employed and fuel consumed in the process of manufacturing beer This restriction of brewing will further have a direct favorable effect on the production of meat and milk, because it will set free for the use of agriculturists—the class which produces meat and milk—a greater percentage of offals (the residuum of the barley used in brewing) than at present produced from brewers' grains At present the brewer returns 25 per cent of the barley he uses in the shape of feeding offals But the barley, when milled—as it is intended to be by this order—gives, in the first place, 50 per cent of flour, which is, of course, direct human food, and, of the remainder, 40 per cent is returned in the shape of what is termed millers' offals The liquor interest has asserted both by advertisement and by misinformed press statements that any restriction of brewing would have the injurious direct effect on feeding stuffs used by agriculturists As a matter of fact, under these restrictions, the contrary will be the case

THE NEW YORK SESSION

Scientific Exhibit

The Scientific Exhibit as the New York Session will occupy the Belvedere on the ninth floor of the Hotel Astor The Belvedere is the summer roof-garden restaurant of the hotel It is a beautiful hall with a glass roof and sides, and occupies the entire width of the building Probably never before has the Scientific Exhibit been so luxuriously housed Applications for space and a plat of the Exhibit Hall will be sent on request to individuals or institutions desiring to make exhibits Applications should be made as early as possible Final assignment of space will be made Monday, April 2, 1917, and all applications for space must be received before that time The exhibit will open at noon, Monday, June 4, and will remain open until noon, Friday June 8 The Scientific Exhibit has come to be regarded as one of the features of the Annual Session, and the exhibit at New York promises to be one of the best ever held Application blanks and further details can be secured from Dr Frederick R Green Director Scientific Exhibit American Medical Association, 535 North Dearborn Street Chicago

List of New York Hotels Recommended by the Local Committee on Arrangements

The local Committee on Arrangements, on recommendation of its subcommittee on hotels, urges those who plan to attend the coming annual session in New York June 4 to 8 to address the management of the hotel of their selection to make reservation directly with the hotel Those who plan to attend the New York session should make their selection and write directly to the hotel, stating the accommodations desired and indicating the rate they are prepared to pay The management of the hotel should be advised of the day on which guests expect to arrive in New York and the length of time they plan to remain The local committee assures those who write for accommodations that they will receive a prompt response from these hotels If, in any instance, a satisfactory arrangement with some one of the listed hotels is not made, write to the chairman of the subcommittee on hotels, Dr Reginald H Sayre, 17 West Forty-Third Street, New York

The accompanying table lists a number of New York hotels indicating the accommodations which are offered and naming the rates per day All rates are for accommodations on the European plan except when, as indicated, the American plan is also offered

David F Sullivan, Frankfort S D (license, South Dakota, 1887) aged 72, a practitioner since 1869, vice president of the Spink County Board of Health, died at his home, January 10

Mary A Latham, M D, Spokane Wash, Cincinnati College of Medicine and Surgery, 1886 aged 72, died in the Sacred Heart Hospital, Spokane, January 20, from pneumonia

Benjamin Franklin O'Daniel, M D, Denver, University of Louisville, Ky 1874, aged 66, died at Mount Airy Sanatorium, Denver, October 15 from chronic interstitial nephritis

James Henry Wilkerson, M D, Knoxville Tenn, Tennessee Medical College, Chattanooga 1892, aged 50, a Fellow of the American Medical Association, died at his home, January 1

Charles Valores Webb, M D., Wallingford, Conn, Hahnemann Medical College, Philadelphia 1898, aged 44, died in the Middletown (Conn) State Hospital, December 26

Gordon White, Nashville, Tenn, Baltimore College of Dental Surgery, 1879, aged 59, a Fellow of the American Medical Association, died at his home December 6

Morris Pitcher, M D, Sardinia, N Y, Tuft's College Medical School 1900, aged 31, a specialist in diseases of the eye, ear, nose and throat, died at his home, January 17

Charles Hope Mullen, M D, Foster, Ky, University of Nashville, Tenn, 1858, aged 78, a veteran of the Civil War, died at his home January 12, from senile debility

William F Phillips, M D, Wilmore, Ky, University of Louisville Ky, 1893, who was stricken with paralysis eight weeks before, died at his home January 19

Nathan A Mossman, M D, New York, New York Homeopathic Medical College New York 1861, aged 79, died in his apartments in New York, January 15

William R Blossom, Caribou Me (license, Vermont, 1903), aged 58, a member of the Maine Medical Association, died at his home, about January 2

Charles J Holmgren, M D, Oakland, Calif, Hahnemann Medical College of the Pacific, San Francisco, 1889, aged 82, died at his home, January 18

Samuel Houston Ridenour, M D, Pittsburgh, University of Pittsburgh, 1890, aged 58, died at the home of his sister in Cumberland Md, January 1

John J Ryan, M D, East St Louis, Ill, American Medical College, St Louis, 1878, aged 72, died in St Mary's Hospital, East St Louis, January 20

W L Noel, Boaz, Ala (license, LaMar County, Ala), aged 68, a practitioner and druggist, died, November 23

Z N Young, Lafayette, Tenn (license, Tennessee, 1889), aged 75, died at his home, about January 17

Thomas G Welch, Mount Scott, Okla (license, Oklahoma), aged 80, died at his home, December 21

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

FIRWEIN

Report of the Council on Pharmacy and Chemistry

Firwein is a product of The Tilden Company, New Lebanon, N Y It is sold under the claim that when swallowed it has a predilection" both for the bronchial mucosa and also for the genito urinary organs To quote

> Expectorant Sedative Antispasmodic in the Treatment of Inflammations of the Bronchial and Genito Urinary Mucosæ
>
> Firwein being a bland soothing balsam possesses a wide range of adaptability and increased potency because of its healing virtues and usefulness as an expectorant, sedative and antispasmodic in bronchitis and inflammation and catarrh of nose throat and lungs '
>
> Firwein has a special predilection for mucosae this being as marked in diseases of the genito urinary system as it is in the respiratory organs In inflammatory diseases of the genito urinary organs its bland, curative properties are exerted in a gratifying degree In cystitis and uritis it is clearly indicated

Little information is given concerning the composition of Firwein An old circular says

> Firwein contains Phosphorus Iodin and Bromin finely blended with a balsameous elixir made from the fir tree

From a more recent circular we quote

> Firwein is prepared from the inside fresh green bark of the fir tree

The label on the product reads

> Firwein is pleasantly and effectively blended with salts of iodin and bromin held in solution with 20 per cent alcohol

The therapeutic claims made for Firwein and the mystery enshrouding its composition make it obvious that the product is intended to appeal to those who are either thoughtless or ignorant This is emphasized by the suggestion that Firwein be combined with (1) cod liver oil (under the claim that it will 'promote the efficiency of the oil"), with (2) whisky for the treatment of bronchorrhea of the aged, and with (3) syrup of hypophosphites for the treatment of persistent bronchitis

As the composition of Firwein is secret the therapeutic claims unwarranted and its use irrational the Council declared it inadmissible to New and Nonofficial Remedies

FIROLYPTOL PLAIN AND FIROLYPTOL WITH KREOSOTE

Report of the Council on Pharmacy and Chemistry

Firolyptol, another product of The Tilden Company is we are told, composed of eucalyptol 10 drops cottonseed oil ½ ounce and Firwein enough to make 1 ounce As the composition of Ferwein is secret it is evident that the composition of Firolyptol is also unknown, except to the manufacturers 'Firolyptol with Kreosote' is said to contain in addition to whatever may be the component parts of Firolyptol 10 minims of creosote to each ounce According to an advertisement, Firolyptol with Kreosote is 'antituberculous antistrumous" and contains all the desired features of cod liver oil and is readily assimilated"

The advertisements of Firolyptol Plain' and "Firolyptol with Kreosote seem to have for their key-note the assertion that cottonseed oil is a particularly valuable nutriment and that when combined with constituents of Firolyptol and Firolyptol with Kreosote becomes particularly valuable to the tuberculous To quote from an advertising circular

> Now that the reconstructive properties of cottonseed oil are better appreciated by the profession the advantages that follow the administration of a palatable emulsion of this strengthening and fattening food product are being demonstrated in hundreds of cases where formerly reliance would have been placed in cod liver oil A recent writer says that pure cottonseed oil is the greatest and purest vegetable oil known to chemistry and will do much toward revolutionizing the treatment of the GREAT WHITE PLAGUE If the treatment of tuberculosis could resolve itself into the administration of a fatty substance in a readily assimilated form there would be no need for any part of FIROLYPTOL but the Cottonseed Oil The toxic material constantly produced in the system by the germs of tuberculosis tend to expose it more and more to the ravages of the disease, and the physiologic functions of the body suffer a constant depression To neutralize this germ activity with a consequent production of toxins it seems most logical to employ such agents as have demonstrated their suitability for such purposes, for which reason Eucalyptol and Kreosote with Firwein are incorporated in FIROLYPTOL

The assertion that cottonseed oil is an especially valuable form of fat is without warrant, but even if it were true the fat is available in cheap and palatable forms in numerous other cottonseed oil products It is unnecessary to discuss the problematical value of creosote in the treatment of tuberculosis or the value of eucalyptol (now generally abandoned) or even of the secret mixture Firwein Food and fresh air, not drugs, constitute the fundamentals of the treatment of tuberculosis and it is both irrational and detrimental to the interests of the tuberculous to administer various potent agents in fixed and unknown amounts with such simple articles of food as cottonseed oil Neither of these products is acceptable for New and Nonofficial Remedies

Editorial Note —Firwein[1] has been advertised to physicians for twenty-five or thirty years and it is a sad commentary on the intelligence of our profession that a preparation sold under such obviously false and misleading not to say silly claims should still be in existence Firwein is claimed to "prevent waste of tissue' in tuberculosis If it had this power it would have found its place long ago among the few great agents in drug therapy As a matter of fact Firwein has gained virtually no recognition outside of the literature of the Tilden concern The claims made for Firwein are a peculiar mixture of studied candor—when the truth is not likely to hurt its sale—and inane vaporing—when the facts would not redound to its credit The Tilden Company declares that Firwein stands without a peer in its class" But the company adds 10 drops of eucalyptol and some cottonseed oil to this peerless product and an improvement is born—'Firolyptol ' Then, to perfect the already perfectly perfected, 10 drops of creosote are added to Firolyptol' and the profession is offered 'Firolyptol with Kreosote"! In just what verbal pyrotechnics the Tilden Company might indulge, should it decide to add ten drops of something else to Firolyptol with Kreosote" one shudders to contemplate

If we are accused of exhibiting undue levity in discussing a therapeutic problem we can only answer that it is impossible to consider seriously the Charlie Chaplins of the nostrum world The following medical journals have during 1916, carried advertisements either of Firwein or Firolyptol with Kreosote or both

MORE MISBRANDED NOSTRUMS

Collins' Ague Remedy, Swaim's Panacea and Swayne's Panacea—James F Ballard St Louis, was made the defendant in three cases brought by the federal government against the respective products named 'Collins' Ague Remedy" which admittedly contained 33 3 per cent alcohol was sold under the claim that it was an effective remedy for chills and fever dysentery, most forms of malarial diseases intermittent, remittent and swamp fevers, cholera morbus and diarrhea These claims the government declared were false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity "Swaim's Panacea" was found to contain nearly 5 per cent alcohol with 62 3 per cent of solids, of which 58 5 per cent was sugar There was also 1/10 of 1 per cent salicylic acid and some sarsaparilla present The public was asked to believe that this stuff was effective as a remedy and panacea for syphilis, pulmonary diseases, eczema, influenza, anemia, consumption and a great many other things These claims were declared to be false and fraudulent and made knowingly and wantonly "Swayne's Panacea" seemed to be very similar in composition to Swaim's Panacea" and was sold under claims virtually identical with those made for the latter product The government officials naturally declared these claims false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity James F Ballard pleaded guilty and was fined $30 and costs—[*Notice of Judgment No 4373*]

---

[1] Three other Tilden products have been the subject of deserved and unfavorable comment in The Journal Narkine in the issue of Oct 24 1908 Hydrocyanate of Iron Tilden in the issue of June 19 1909 and Febrisol ' in the issue of June 29 1912 The first two articles are reprinted in the latest (9th) edition of The Propaganda for Reform '

Croxone—The American Croxone Co, Cleveland, Ohio distributed this product The government chemists reported that each small box of the product contained 32 capsules in each of which was a white-coated pill and a red oil The oil was essentially a small amount of oil of pine or oil of juniper dissolved in a fatty oil or mixture of oils The pill consisted essentially of strychnin, a trace of brucin, aloin hexamethylenamin, lithium carbonate, potassium nitrate and probably a trace of atropin The stuff was sold as a 'cure for rheumatism and kidney disease and a preventive of dropsy and gravel" These claims were declared false and fraudulent and applied knowingly The company pleaded guilty and was fined $25 and costs—[*Notice of Judgment No 4386*]

Freeman's Balsam of Fir Wafers—Edgar S Fossett, who did business under the name Freeman Pharmacal Company Portland Maine, manufactured 'Dr Freeman's Balsam of Fir Wafers' which the government declared misbranded Federal chemists reported that the lozenges consisted of sugar with very small amounts of oil of turpentine and eucalyptus with the possible presence of a trace of balsam of fir They were sold under the claim that they were an effective remedy for relieving consumption and for stopping the raising of blood in consumption' and effective also as a remedy for all affections of the throat and lungs, bronchitis, asthma croup whooping cough, la grippe, etc These therapeutic claims were declared false and fraudulent and applied knowingly and wantonly Furthermore, the fact that the name of the product would indicate that the article contained an appreciable amount of balsam of fir (which it did not) further constituted misbranding Edgar S Fossett entered a plea of *nolo contendere* and was fined $40—[*Notice of Judgment No 4391*]

Renne's Pain Killing Oil—This was another preparation put out by James F Ballard of St Louis, who in this case did business under the trade name 'Dr Herrick Family Medicine Co" The chemists of the Bureau of Chemistry declared that analysis showed it to be essentially a water-alcohol solution of sassafras oil and cayenne pepper containing 78 6 per cent alcohol and 4 per cent volatile oils There were also indications that the stuff contained a little mustard oil and soap The government charged Ballard with falsely and fraudulently claiming in reckless and wanton disregard of the truth of the statements, that this stuff was a reliable remedy for cholera, diphtheria, rheumatism, croup and a number of other conditions Ballard pleaded guilty and was fined $10 and costs—[*Notice of Judgment No 4400*]

Schuh's Yellow Injection and Schuh's White Mixture—The Schuh Drug Co, Cairo Ill put both these products on the market The first was sold under the claim that it was "a Speedy Cure for Gonorrhea and Gleet Cures in 3 to 5 days" The federal chemists reported that Schuh s Yellow Injection was an aqueous solution of boric acid carbolic acid and berberin The government charged naturally that the therapeutic claims made for this nostrum were wantonly and recklessly false and fraudulent The second preparation, Schuh s White Mixture" also was analyzed by the government chemists who reported that it was a mixture of mucilage of tragacanth balsam of copaiba, and probably sandalwood oil, flavored with cassia This stuff was sold as "a Safe and Certain Cure for Gonorrhea and Gleet Cures in 3 to 5 days" and other similar claims These, of course, were declared false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity The Schuh Drug Company pleaded guilty and was fined $10 and costs—[*Notice of Judgment No 4396*]

Elmore's R'eumatine Goutaline—"Dr D M Elmore's R'eumatine Goutaline" was put on the market by George Bayne, Bayonne N J, under the claim that it was a remedy for all rheumatic disorders and all forms of rheumatism and a remedy for all disorders of the kidneys, liver and bladder, besides being effective for curing malaria The government chemists reported that the stuff was apparently a dilute tincture of colchicum The claims made for it were declared false and fraudulent and applied wantonly and recklessly George Bayne pleaded guilty and was fined $10—[*Notice of Judgment No 4374*]

Armstrong's Croup Ointment—Harold G Carpenter and Herman J Pierce manufactured and sold this product under the trade name, Carpenter & Pierce Co, Troy, Pa It was claimed to be a cure for croup, catarrh, asthma, and cold in the head, throat or lungs The government chemists reported that this ointment contained eucalyptus oils and traces of other oils possibly cassia and thyme The therapeutic claims were declared to be false and fraudulent A plea of *nolo contendere* was entered by the defendants, who were fined $10 and costs—[*Notice of Judgment No 4375*]

Anticephalalgine—The defendant in this case was James I Johnson, a corporation, Raleigh, N C The stuff admittedly contained 30 per cent alcohol and 4 grains acetanilid to the ounce The government chemists reported that it also contained sodium bromid sodium salicylate, caffein and antipyrin It was sold under the claim that it was a cure for all kinds of headaches, claims that the government officials declared were knowingly false and fraudulent The defendant pleaded guilty and on payment of costs the court suspended judgment—[*Notice of Judgment No 4376*]

Wright's Rheumatic Remedy—The Wright Medicine Company Peru, Ind, made this preparation which, according to government chemists, was an emulsion composed principally of turpentine, methyl salicylate, sugar acacia, and water, with probably some resinous or plant extractive matter It was sold under the claims that it was an effective remedy for gallstones and a specific remedy for kidney and bladder troubles These claims were characterized by the government as false and fraudulent and made knowingly and in reckless and wanton disregard of their truth or falsity The company pleaded guilty and was fined $50 and costs —[*Notice of Judgment No 4398*]

H G C—This preparation was manufactured and sold by the Acme Chemical Mfg Co, New Orleans, La According to the government chemists the product was a watery solution of borax and berberin sulphate It was sold under the claim that it was a cure for gonorrhea, gleet and leucorrhea, a claim that was declared false and fraudulent The company pleaded guilty and was fined $100 and costs —[*Notice of Judgment No 4397*]

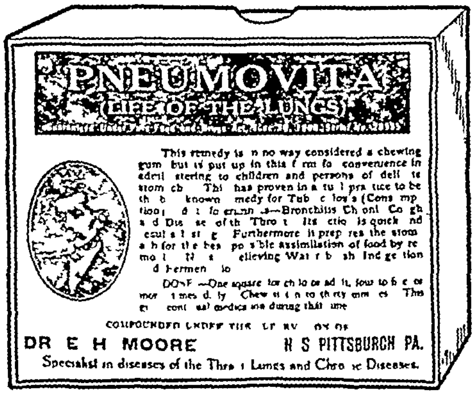
ACME CHEMICAL MFG. CO LTD., New Orleans, La.

Russell's White Drops—This soothing syrup" was manufactured by the Russell Medicine Co, Providence R I and was sold under the claim that it was an invaluable remedy for the relief and cure of diarrhea and dysentery, that it would prevent convulsions and was a remedy for cholera infantum and all diseases incident to children, especially during teething Further, that it would give new life and vigor to the whole system The claim also was made that it contained nothing that would injure the most delicate child Government chemists reported that the stuff contained from 13 to 16 per cent of alcohol as well as codein, a poisonous and harmful drug The therapeutic claims were declared false and fraudulent and applied knowingly and wantonly The company pleaded guilty and was fined $20—[*Notice of Judgment No 4388*]

Pneumovita—Edwin H Moore Pittsburgh Pa, sold this stuff as the best remedy known for Tuberculosis, (Consumption) and its forerunners—Bronchitis, Chronic Cough and Diseases of the Throat" The government chemists reported that the stuff was a sweetened gum containing small amounts of charcoal and iron phosphate having a wintergreen flavor Of course the claims made were declared false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity Edwin H Moore entered a plea of *nolo contendere* The court imposed a fine of 6¼ cents, with costs of $15 07—[*Notice of Judgment No 4394*]



Correspondence

Sodium Cacodylate in the Treatment of Syphilis

To the Editor —Dr William G Ward's letter (THE JOURNAL, Feb 3 1917, p 390), and the recent admirable article by Dr Harold N Cole (THE JOURNAL, Dec 30, 1916, p 2012) recall to mind Dr J B Murphy's clinical note on the use of sodium cacodylate in the treatment of syphilis (THE JOURNAL, Sept 24 1910, p 1113), and the experimental work of Capt H J Nichols, U S Army (THE JOURNAL, Feb 18, 1911, p 492) The results of Nichols work conclusively proved, at least from a laboratory standpoint, that this drug was of very little value as a spirocheticide in combating syphilis Prior to the publication of Dr Murphy's letter, I had *employed sodium cacodylate extensively as a remedy in* psoriasis, and I still continue to use it in selected cases of the disease

Adopting Dr Murphy's suggestion I gave the agent an extensive trial in syphilis in all stages of the disease The results were extremely disappointing, from both clinical and serologic points of view More recently during the scarcity of salvarsan, I gave the drug a second trial employing it in large dosage in the hope that the previous failure had been due to the employment of insufficient amounts The results were not tabulated but, judging roughly from my experience in a score of cases its therapeutic value as an antisyphilitic was nil A few of the patients underwent a temporary improvement probably owing to the tonic effect of the drug, but in every instance the serologic findings were unaffected

R L SUTTON M D Kansas City, Mo

Compulsory Health Insurance

To the Editor —Your invitation to discuss health insurance is too attractive to be ignored During the past eight months I have read many articles by American physicians on the subject, and I have been saddened by the general tone of quiescent acceptance Those advocating insurance are entirely altruistic This group is not composed of employers, but employers will welcome the move so far as it increases economic efficiency better than other methods The altruistic workers are depending on the medical profession to educate the insured to want insurance and to keep its own remuneration low enough to make the plan feasible

Dr Lambert has had unequaled opportunity, and is probably the best informed man in the medical profession on this subject He makes no mention of advantages pro or con but contents himself with discussing details This assumption that the thing must be I consider a mistake It is the mistake which harassed the profession in England in 1912 and caused the failure of its combative efforts

Dr Lambert's report states that, after twenty-five years' experience European countries have concluded that any plan for voluntary insurance is a failure The profession agrees with insurance workers in this conclusion These countries then decide that the remedy is compulsory insurance Since volition is a failure, then compulsion must be successful This reasoning is insufficient yet five countries in a period of three years did adopt it Sufficient time has elapsed in these instances to prove that friction is continually present and will continue to be until such time as free choice of physician and unchanged relationship between patient and physician may be allowed, instead of a commercial physician hired by a third party and called through expediency This point is the greatest stumbling block that has been encountered, and it is so entirely because of increased and prohibitive expense Patients want it and the profession wants it, yet it has been necessary to ride over it with no one achieving satisfaction except the carrier of insurance

As to relative conditions, the report of the American Medical Association Health Insurance Committee shows that Norway under a voluntary plan insures 25 8 per cent, England, before the act of 1912, insured 31 per cent, and France, voluntary 10 or 12 per cent In the United States it is estimated that labor unions alone insure 10 per cent, so that when other agencies are accounted for, it seems that we are in fully as good a position as were European countries previous to the adoption of compulsory plans

Under the compulsory plan Germany has seen physicians go on strike after ten years over the free choice contention, has seen their clientele uphold them to the defeat of strikebreakers and of the organization, has temporized, and the end is not yet England at present deplores the fact that its medical profession has not improved the quality of its work as was planned in 1912 Just how or why a physician could or should improve as a salaried commercialist over what he was as a friend, trusted by choice with the lives and health of his clientele, is not clear, especially when he is handicapped by more pieces of work at a smaller rate of recompense It was, however, in the plan that he should improve, and the fact that improvement has not occurred is a bitter disappointment which is now producing complaint

None of these five countries has yet proved that compulsory insurance can be continuingly operated with satisfaction to all or even to any, of the three parties concerned—and this under forms of government in which policies can be stable and reasonably permanent! One of the misfortunes of our form of government is that no policy which works any dissatisfaction even though it is a good policy, can be maintained with any reasonable degree of preplanning or permanence a quadrennial upheaval may change all arrangements which have been made by injecting into the administration a new personnel with fresh ideas

Agreeing that the panel plan recommended by the American Medical Association committee is the most feasible for use and the least undesirable I doubt if good men in sufficient numbers could be found to serve as referees, to check up the work of the medical profession on points of judgment, inability for work inadvisability of working, etc I cannot conceive of men capable of passing those nice judgments, men whose intelligence and integrity the profession could respect, belittling themselves to the point of resigning practices to take up work of this class for the benefit of an employer who paid them a clerk s salary Men of sufficient caliber to be capable of such work would invariably be too big to need it and too free to want it, while men willing to accept the jobs would invariably be of too small caliber to be of trustworthy judgment, because our territory differs from that of England and the European countries In England men could accept the act and work under it or they could starve for there was no other place to work In the United States, for many years to come, men unwilling to empanel have the option of leaving the industrial centers to work in country communities where only a negligible proportion of the population would fall under insurance classification Good men could feel confident of doing well in choosing to emulate Aesop's hungry wolf On the other hand, mediocre men who had been unable to build up satisfactory practices in country territories could come to the industrial centers, empanel, and be granted a regular amount of work and three meals a day, to their own betterment and to the detriment of the insurance workings

While these insurance plans were being evolved in Europe, little was being done in the way of preventive medicine

Had our present-day knowledge of public health and sanitation been available and in general effective use, there is question that paternalistic governments would ever have attempted so fantastic a scheme as that of acting as financial fathers to their entire population

The trend of opinion among American writers is that health insurance is inevitably coming and that we should adjust our affairs to it by entering now into petty bickerings and bargainings over the details of its arrangement If it were a proved blessing I should agree with this view, even though it reduced medical men to the class of salaried workers and members of a trade union, but it is not proved None of the European plans has shown a greater humanitarian or economic improvement than could very probably be attained by the employment of the sanitary methods and instruction with which present-day knowledge is enabling them to handle their armies were these methods applied to civilian population, accompanied by government money and government compulsion in amounts equivalent to those which have been expended annually on the older idea

I should like to see the Council on Health and Public Instruction of the American Medical Association and the committees of all state societies offer programs as a substitute for social insurance activities, and work in such fashion that laymen, the press and our legislative bodies understood the reasons therefor I believe that all would have great cause to be satisfied with the increased economic output as compared with the results of the older method which has been heralded as new

W D Chapman, M D, Silvis, Ill

Mouth Sepsis

To the Editor —Considerable attention has been bestowed on oral sepsis as an essential etiologic factor in systemic infections, and there is reliable scientific evidence in support of the tooth-root theory of this large class of diseases The fact that chronic septic foci in teeth and elsewhere are exceedingly difficult to recognize in the majority of cases is undoubted It is particularly instances of periapical infection or abscess that offer the greatest difficulty in this respect Here, even a Roentgen examination which should always be made by an expert, may fail to render reliable aid

Daland states that the diagnosis of mouth sepsis should be made by a dentist who is specially trained for this, in which opinion I concur The physician, however, who encounters a case of systemic infection in which the teeth are suspected should refer the patient to a competent nose and throat specialist with a view to eliminating all foci other than those which may be present in the mouth before invoking the services of the specially trained dentist It sometimes happens that multiple foci are discoverable in as many different organs, as the teeth, tonsils and sinuses

Successful treatment of secondary systemic infection demands, first and foremost, the removal of the septic focus or foci on which they depend Before reducing the masticating surface of a particular patient however, the evidences of an existing necessity for so doing should be as clear and convincing as possible An attempt by a competent dentist should be made to heal the morbid lesions in and about the tooth roots, since some of these are amenable to expert management, before ordering the extraction of the teeth

Within the past six months a number of dentists have informed me that countless teeth are being removed without justification, on the advice of physicians, usually following a Roentgen examination (by amateurs in many instances) In well authenticated cases in which one or two teeth were the seat of peripheral infection physicians have gone so far as to give emphatic directions to the effect that all of the remaining teeth be extracted For example, one of Philadelphia's best known specialists in extraction was requested by a physician to pull out all of a certain patient s teeth—twenty—but he courteously, though firmly, declined to do so

It seems to me that the rapidly growing custom of sacrificing teeth, many of which are merely suspected of being septic, cannot fail to arouse the most ardent activity of dentists in opposition thereto, and must prove the ultimate chagrin of the medical profession It would appear that an amazingly low estimate is being placed on the value of human teeth by an increasing number of physicians, who should appreciate the importance of a good masticating apparatus to the digestive function—to the maintenance of health

I do not mean to disparage the significance of these latent chronic septic foci as a cause of secondary systemic infections or to depreciate investigations in this, comparatively speaking new field of endeavor The object of this letter is to utter a word of warning with a view to lessening what I believe to be an unwarrantable present-day sacrifice of the masticating surface, and to spare the medical profession the adverse criticism of the future, by a broader conception proper to the subject of oral sepsis and its management in the present

Request for Names of Hospitals Facing Public Parks

To the Editor —I would appreciate the receipt from readers of The Journal of the names and addresses of hospitals facing public parks I wish the information to present to our city council, which is considering an ordinance prohibiting the building of a hospital within 200 feet of a public park

M M Enos M D Delger Building Oakland, Calif

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

ELIMINATION OF DIPHTHERIA BACILLI IN DISCHARGING EAR

To the Editor —I am writing to know if you may be able to suggest anything relative to the subjoined case

P L boy aged about 2½ years, contracted scarlet fever which ran the usual course At no time was there an unusual sore throat and there was never any membrane of the tonsil The small amount of throat trouble cleared up in a few days

About the second week of the child's illness the mother who was attending him and doing her work, developed diphtheria Ten thousand units of antitoxin were used on the mother and 1,000 on the child as a preventive, and a trained nurse was employed There was no reaction to the antitoxin in the child The mother made an uninterrupted recovery Shortly after the mother had contracted diphtheria, the child developed a discharging ear When the time came for the lifting of the quarantine *a culture was made* from the discharge of the child's ear and the diphtheria bacillus was discovered The culture from the mother's throat was negative Repeated cultures from the child's ear have shown the germ to be present and finally a laboratory test was made with the guinea pig to see if the germs were virulent The pig died in thirty six hours and the diphtheria bacillus was found in the pig

As stated before the child is apparently well otherwise and is regaining his strength and gaining in flesh What am I going to do to get rid of this germ? Everything that I have used has been of no avail and I have not found anything in my available literature to help me

W B Wallace M D Detroit

Answer —This case emphasizes the necessity of making cultures from all discharging ears, since virulent diphtheria bacilli are found in the ears much more often than is generally supposed The failure to get rid of the bacilli is probably due to local conditions which prevent antiseptic or germicidal agents from reaching the focus of the bacilli Examination of the ear should determine whether the drainage is free and whether the perforation in the drum head is too small or so situated that free drainage is not secured Any such unfavorable conditions should be corrected by the aurist As in the nose and throat so also in the ear, persistent carriage of diphtheria bacilli is usually dependent on some local condition which must be corrected to facilitate the elimination of the bacilli

HYDRORRHEA GRAVIDARUM

To the Editor —A woman aged 32 secundipara who had a miscarriage about six months ago whose present temperature is normal the pulse 68 and who has had no menstruation since Oct 5 1916, while going about her housework Jan 12, 1917, passed a quantity of fluid which she believed to be a rupture of the 'bag of waters' For about two hours she experienced sharp pains in the lower abdomen of the nature of labor pains January 13 I made bimanual examination and found the uterus enlarged to about the size of a three months pregnancy but the organ was hard like a normal uterus The pains have ceased entirely There has at no time been any sign of hemorrhage Could this be hydrorrhea gravidarum? What is the proper method of procedure on the supposition of pregnancy? I have maintained that curettage would be proper Please advise Would you not expect to find the uterus soft and patulous if this were a pregnancy? Please do not publish signature F S D

Answer —The escape of fluid from the urogenital tract during pregnancy may be due to incontinence of urine, hydrorrhea decidualis or hydrorrhea amnialis In this case it is possible that the cause is a hydrorrhea decidualis, that is, a collection of fluid is formed between the decidua vera and the egg, perhaps as a decidual cyst, which eventually is discharged through the cervical canal The hydrorrhea amnialis, due to rupture of the membranes probably high up in the uterus, is generally attended with slight bleeding The firm consistency of the uterus found on examination was probably due to its contraction at the time of the examination Whatever the cause of the discharge, the proper treatment is prophylactic treatment for abortion, that is, rest in bed and, if necessary, opiates The chance for the continuance of gestation is better in hydrorrhea decidualis, although even if the discharge is from the liquor amnii the rent in the membrane may close and pregnancy may continue

CERTIFIED MILK

To the Editor —Please advise me as to the requirements necessary to establish a certified milk business I particularly desire to know whether a local certified milk organization would have to be connected with another certified milk organization or would have to get permission to use the trademark of certified milk

W G Bain M D, Springfield, Ill

Answer —To establish a certified milk business, a dairyman must be willing to cooperate with a medical milk commission and fulfil its specifications The local medical milk commission need not be connected with any other certified milk organization It would be advisable, however, to limit the term certified milk" to milk produced in accordance with the requirements of the American Association of Medical Milk Commissions These requirements may be obtained by consulting the annual reports of the association, and also Public Health Report 85 published May 1 1912 The secretary of the American Association of Medical Milk Commissions is Otto P Geier, M D, Ortiz Building, Cincinnati

SUBSTANCES INTERFERING WITH REACTION FOR SUGAR

To the Editor —What substance or substances in the urine which fail to reduce Fehling's solution are fermented by yeast? I recently examined the urine of a supposed diabetic Fehling's test was negative acetone and diacetic acid were present in great excess and the fermentation test showed 1 6 per cent of sugar (if sugar it was) That the Fehling's solution had not deteriorated was shown by the fact that on the same day it reacted promptly to a specimen shown by the fermentation test to contain 1 2 per cent of sugar H B

Answer —For practical purposes there is no substance in the urine fermented by yeast that does not reduce Fehling's solution, provided proper technic is employed The reducing action of glucose, or other sugars is diminished by strong alkali Furthermore the urine contains some compounds which interfere with the detection of glucose with strongly alkaline solutions In addition urine contains certain substances which prohibit the immediate precipitation of the cuprous hydroxid or oxid Care must be exercised that the concentration of the alkaline cupric tartrate and the sugar is relatively low

CHVOSTEK'S SIGN

To the Editor —In The Journal Jan 13 1917 p 157 appears an abstract on the facialis phenomenon or Chvostek's sign Will you kindly inform me how to elicit this sign?

Edwin A Tuits M D Arkansas City, Kan

Answer —Chvostek's sign is a peculiar excitability of the muscles of the face so that spasms are produced if the trunks of the facial nerve are lightly percussed This occurs particularly in tetany, occurring in this condition even if the skin is lightly stroked

Food Requirement and Food Consumption —The discrepancies which are so frequently to be observed between food requirement and food consumption may be explained as due in part to present lack of adjustment to recent and enormous changes in environment and human activities and in the nature of foods It seems quite possible that adaptation of diet to the activities of the organism, and other important hygienic measures, may come about, not simply through the slowly accomplished downfall of degenerate classes and nations, which history has so often shown us—for neither the rich fruits of shrewd business capacity nor the activities of the altruistic can ultimately shelter physical degeneration—but through the further discovery of the principles of scientific management of the human organism, and through the apprehension of these by the enlightened classes and the consequent practice of them by the world's population —Minna C Denton, *Scientific Monthly* December, 1916

Book Notices

On Modern Methods of Treating Fractures By Ernest W Hey Groves, M S M D, B Sc, Surgeon to the Bristol General Hospital Cloth Price $2 75 net Pp 286 with 136 illustrations New York William Wood & Co, 1916

In this small volume the author tries to choose that which he considers best in the modern developments of the treatment of fractures, and substantiates it wherever possible by extensive experimental work He assails separately the principles of the "classical school, which aims at setting the bone, prolonged immobilization and fixation of the neighboring joints leaving the soft parts to take care of themselves In their stead he advocates the intelligent employment of the modified methods of Bardenheuer on continuous extension of Lucas-Championniere on early massage and motion, and of Lane on open operation Causes for bad results in the various types of fractures treated by different methods are discussed A special chapter is devoted to the various types of external extension appliances, as Buck's extension Bardenheuer's extension methods the Balkan splint Hodgen's splint, and the crutch splint of Borchgrevink for fractures of the humerus Mechanical modifications of these external methods are detailed, as the Steinmann nail extension, and double transfixion apparatus of Lambert and Groves About 100 animal experiments are given, showing the relative values of a great many operative methods of fixation of the fragments as plates and screws, plates and cotter pins, and intramedullary pegs of bone living and dead, ivory, horn, metallic magnesium and steel There is considerable comment on bone regeneration and the healing of comminuted fractures The work is concluded with a chapter on the operative treatment of special fractures, giving the author's results

Diseases of Occupation and Vocational Hygiene Edited by George M Kober, M D LL D and William C Hanson M D Cloth Price $8 net Pp 918, with illustrations Philadelphia P Blakiston's Son & Co 1916

This work deals with a multitude of subjects which should be of vital interest to a variety of people, the physician the employer, the worker and last but by no means least, the legislator For the physician especially, it contains information concerning the diseases which are caused or aggravated by the different kinds of employment Although the various articles are from the pens of different writers, they show a commendable tendency to stick closely to known facts The chapter on 'Cancer and Occupation' is an example of this The more important theories of the etiology of cancer are discussed in an unbiased manner

The conclusions reached may be briefly summarized as follows Concerning a specific infection, 'Repeated attempts to isolate such an agent from mammalian tumors have invariably failed' the question of contagion 'has never been demonstrated' concerning heredity 'while the data collected up to the present time from animal experimentation are insufficient to serve as a basis for any sweeping conclusions concerning human inheritance we are of the opinion that the results already obtained are sufficient to call for a reconsideration of the subject of heredity with reference to cancer", concerning injury, the principal cause would appear to lie in the peculiarity of the individual, for trauma is of so great frequency that it cannot in any sense be regarded as the specific cause of any type of tumor", in regard to chronic inflammation as a basis for cancer, 'there are agents to which all individuals are exposed to a greater or less degree that are mildly injurious The undue or prolonged exposure of the skin to such agents evidently has a tendency to bring on a premature senility of its tissues especially in certain individuals Since however most of the tumors of this type are of comparatively slight malignancy such influences are not of first importance' No very marked preponderance of cancer in any of the more usual occupations is shown by Newsholme's Statistics" The effect of Roentgen ray in this connection is recognized but 'there are as yet no reported cases of carcinoma arising from radium burns" However the similarity between Roentgen ray and radium should warn against the indiscriminate or careless use of this agent It is perfectly evident from the above that the real cause of cancer is not yet known, nor can cancer be directly connected in a causal way to any particular occupation

The work was written for laymen as well as physicians and many employers might derive much profit in the way of better and more efficient work by their employees if more attention were given to better hygienic conditions in the shop factory, etc, but there seems to be few of them who are longheaded enough to see that far Not the least among those who might derive much benefit from the careful study of this work are legislators In this day of legislative mania, when quantity seems to be a greater desideratum than quality, much half baked and even unbaked legislation is being passed, particularly along the line of so called health laws

Disturbances of the Heart Discussion of the Treatment of the Heart in Its Various Disorders, with a Chapter on Blood Pressure By Oliver T Osborne A M M D, Professor of Therapeutics, Yale Medical School Second Edition Cloth Price, 75 cents Pp 269 Chicago The Journal of the American Medical Association 1916

Safe and sane guides to therapeusis are particularly needed in diseases of the heart and blood vessels which occur frequently and in which much can be accomplished for the patient by rational measures Osborne presents a concise description of the methods of treatment indicated in these diseases In the chapters on blood pressure, proportionately more full than those dealing with other cardiac disturbances, the methods of determining pressures are discussed, together with the significance of high and low pressures, as related to the heart itself and as indexes of the presence of concomitant conditions Chapters on pericarditis, myocardial disturbances, endocarditis and chronic valvular disease follow Heart disease in children and in pregnancy are discussed, as are also the problems of therapy arising in cardiorenal disease Abnormalities of rhythm and rate are considered in the light of recent studies with the electrocardiograph The section on the indications for therapy in angina pectoris and heart block are brief but to the point The importance of chronic infections as a cause of the pain in pseudo-angina might profitably have received more emphasis As a concise statement of what to do and what can be accomplished in the treatment of disturbances of the heart and blood vessels, this manual can be heartily recommended to all practitioners of medicine

Manual of the Medical Department United States Army Cloth Pp 395 War Department Document No 504 Washington Government Printing Office 1916

This manual, prepared under the supervision of a board consisting of Lieut-Col Henry C Fisher and Majors Elbert E Persons and Reuben W Miller, Medical Corps, presents many features which offer opportunities for efficiency not found in previous manuals As it now appears, the manual is a complete treatise on medicomilitary administration, so arranged that even the neophyte may read and understand it Instead of including all the information bearing on military administration which is to be found in the army regulations general orders and service manuals, which should be in the hands of all medical officers, the manual contains an appendix which refers by subject headings, to the more important orders containing matters of interest to medical officers If the manual and appendix were printed on loose leaves and assembled after the method of the U S Navy Regulations it would be possible to print changes in regulations on loose leaves which could be inserted This would avoid the haphazard method, at present necessary, of clipping orders and circulars and pasting them in the manual, to the eventual detriment of the binding by reason of bulk Many sections of the manual have been rewritten, new articles have been added, and all matter has been brought up to date One aid to the student of the manual is the introduction of subject running heads on the right hand pages

More Hospitals—The greatest need of practical medicine today is more and better equipped hospitals—V C Vaughan, M D, *Science*, Dec 8, 1916

Social Medicine, Medical Economics and Miscellany

Fatal Case of Periodic Vomiting with Acetonemia in a Child

A case reported recently by P Busacchi in a boy of 4 had all the features of this syndrome except that the attacks came on without any vomiting The prostration each time was severe, with coma and fever and the acetone odor of the breath was intense while the urine contained notable amounts Another child had repeated attacks, but only one was known to be accompanied by vomiting He suggests, therefore that the syndrome had better be called hemo acidosis of the cyclic or acyclic type, with convulsions or depression as the case may be In a recent case a boy of 6 previously robust was taken suddenly with severe vomiting and high fever and he became unconscious with erythema of the face and trunk convulsions and coma dying within twenty-four hours The odor of acetone was strong in the breath and urine throughout and the Kernig sign was pronounced Nothing was found in the vomit or stools to suggest poisoning from without The necropsy findings excluded meningitis and other probable causes, the syndrome being thus evidently the work of hemoacidosis of the convulsion type The thymus and lymph glands were enlarged Busacchi knows of only eleven cases on record with a fatal outcome, and only a few had necropsy control His little patient had never shown signs of a nervous predisposition and nothing was found to indicate acute or chronic indigestion or appendicitis, but a sister of 9 had presented two similar severe attacks The mother had died at 39 She had been subject to headache and arthralgia In connection with a possible gouty basis for the trouble Busacchi relates that the urine in the first case mentioned above contained a large number of uric acid crystals during the days following an attack Comby regards the syndrome as an equivalent for the manifestations of the exudative diathesis In Busacchi s fatal case the viscera had evidently suffered recently and severely from the acidosis, the changes in the kidneys being enough to explain the fatal outcome In his report, which appeared in the *Rivista Critica di Clinica Medica,* 1916, **17,** 473, he discusses the pathogenesis and reviews the literature on the subject The fatty metamorphosis found in the liver is, he thinks, merely secondary, as the children always seemed well and strong outside of the attacks

---

Nature of Gout

R Bass and R Herzberg have recently published some researches in this line, according to a summary of their work in the *Norsk Magazin for Lægevidenskaben* They recall that the variations in the output of uric acid in gout—'uric arthritis"—may depend on the secreting power of the kidneys so that it is necessary to determine the uric acid content of the blood in estimating the case But this examination of the blood generally does not take place until the attack of gout is fully developed By that time the diet has already been changed in order to arrest the attack This change to a purin-free diet rapidly reduces the uric acid content of the blood, whether or not there has been a preceding attack of gout In order to study the influence of an attack on the uric acid content of the blood, it would therefore be necessary to refrain from reducing the purin elements of the diet during and after the attack, or else the conditions would have to be studied in a patient having an attack on a strictly purin-free diet The influence of drugs must also be excluded Three patients were put on a purin-free diet during an attack, and the uric acid in 100 c c of blood dropped from 7 2 to 5 from 5 5 to 4 and from 4 3 to 2 7 mg In two others who had been on a purin-free diet before the attack, the uric acid in the blood kept at exactly the same figure during the attack, and when reexamined one and three weeks later namely, 5 and 3 2 mg Other patients were on a purin-containing diet both during and after the attack and these had approximately the same figures for the uricacidemia during and after the attack, in only one case was there a difference amounting to 0 4 mg Spontaneous attacks of gout can thus develop and subside without modifying the uric acid content of the blood

Experience has shown however, that ingestion of large amounts of purin-producing foods can bring on an attack of gout at the same time that the uric acid content of the blood increases In order to ascertain whether it is the uric acid which works on the joints, Bass and Herzberg injected intravenously considerable amounts of sodium urate, up to 1 8 gm of uric acid in 100 c c of fluid But this never induced symptoms in the joints even in gouty persons who were extremely subject to attacks and even when the uricemia rose to 10 mg It is probably therefore not the uric acid as such, but other intermediate purin substances which elicit the pains in the joints, such as the nucleosids or purin bases The article of Bass and Herzberg appeared in the *Deutsches Archiv fur klinische Medicin* 1916 **119,** 482 and concludes with the deduction from the foregoing research that uricacidemia cannot be regarded as the specific feature of gout Merely the distribution of the uric acid in the body seems to be the characteristic of gout F Muller calls uric acid an ' arthotropic substance ' but the uric acid content of the blood and of the fluid in the joints proved to be approximately the same in a large number of tests, including some on the cadaver the joints punctured after death None of these subjects had had attacks of gout, but in two patients who had succumbed to uremia, uric acid was found in the joint fluid in a concentration of 18 5 and 20 8 mg, while the blood content was only 10 and 8 2 mg There thus exists in fact an abnormal attraction for uric acid in the joints in gout which does not occur in other affections Persons with gout have evidently an exceptionally high capacity for taking up uric acid in the tissues With intravenous injection of uric acid, the blood content keeps at the same level so long as the kidneys eleminate it properly But in the gouty the uricacidemia is lower, nothwithstanding reduced elimination in the urine More uric acid, therefore must be taken up by the tissues in the gouty than in other patients

---

Pregnancy Toxicoses

Our Norwegian exchange brings an abstract of an article on his subject by L Seitz in the *Therapeutische Monatshefte,* 1916 p 173 Seitz advises in treatment of eclampsia a combination of Stroganoff s prophylactic method and venesection to relieve the high blood pressure and get rid of some of the toxins in the blood These measures are supplemented with subcutaneous infusion of Ringer's solution, and the patient is made to drink freely of lemonade The childbirth must be hastened as much as possible with gentle means, avoiding all severe operative intervention (The Stroganoff method was described in THE JOURNAL, Feb 12, 1916, p 530) With pregnancy nephritis the retention of salt and water is best combated by bed rest, and this must be absolutely enforced The kidneys are spared further by avoiding intake of salt keeping to milk alone As a rule under these measures the nephritis subsides entirely, so that the pregnancy can go on to term In only a very few cases is it found necessary to interrupt it Generally speaking, the nephritis which develops acutely with sudden and pronounced edema and albuminuria is the most dangerous Seitz combats pregnancy dermatoses with a milk-vegetable diet, bed rest and subcutaneous injection of Ringer s solution If this does not cure, he tries injection of horse serum or 20 c c of serum from a normal pregnant woman Rest and dieting are the main things An essential element in the treatment of the incoercible vomiting of pregnancy is the removal of the patient from her wonted surroundings The first one, two or three days after she reaches the clinic she is allowed nothing whatever by the mouth, but saline is given by the rectum by the drip method eventually with addition of potassium bromid R Freund has also found injection of serum gives good results Only a few cases prove intractable. These refractory cases are more of a toxic than of a nervous character, and the uterus will have to be evacuated Dryness of the tongue, offensive breath, bad pulse, albuminuria and especially a rise in temperature call for the arrest of the pregnancy without delay

Validity of Regulations Bearing on Transportation of Milk into City

(City of Chicago vs. C. & N. W. Ry. Co. (Ill.) 113 N. E. R. 849)

The Supreme Court of Illinois reverses a judgment imposing a fine of $100 on the defendant for delivering in the city of Chicago Aug. 21, 1914, milk at a temperature of from 67 to 76, or higher than 55 F., the milk having been brought to the city in baggage cars having no refrigerating facilities, the trip taking in the neighborhood of two hours. The city charged violation of an ordinance covering in detail practically all matters regarding the supervision of the production, handling and delivery of milk to be sold within the city—not only its treatment in the city, but on the farm from whence it is shipped, including the straining and cooling of the milk immediately after the cows are milked and the temperature at which it shall be kept from that time until it is delivered to the consumers in Chicago. The court says that counsel for the defendant admitted that a municipality has the power to regulate what kind of milk shall be sold within its limits, and that such rules and regulations may indirectly affect the production of the milk on the farms outside the city limits, and that it may thus apply regulations that will in effect require milk to be cooled immediately after it is taken from the cow and to be kept cool until transported to the city for delivery. This is undoubtedly the law. This court, in construing certain provisions of this ordinance with reference to the regulations for pasteurizing milk, upheld the validity of the ordinance in that respect, and, in effect, held regulations such as are before the court in this case valid provided they are reasonable and are adapted to the objects sought to be attained. The court thinks that, under any fair construction, the ordinance was intended to apply to common carriers in the transportation of milk from the country to the city; otherwise it would be ineffective. The object sought to be obtained would be absolutely defeated if common carriers, in the transportation of milk from the country to the city, were not required to keep it cool in transit. The court does not agree with the contention that as common carriers ordinarily must accept all freight tendered therefore they would not be justified in refusing to receive cans of milk even though they were not within the limitations of temperature required by this ordinance. The common carrier should not be permitted to be the one agency of those handling milk between the time it is milked and the time it reaches the consumer to defeat the purposes of a reasonable health ordinance on that subject. But it was contended that the ordinance here in question, if intended to apply to common carriers, was invalid, being unreasonable in its method of regulation, that other provisions of the ordinance require that cans of milk be sealed before they are shipped and that the seals shall remain unbroken during transportation by the carrier, and that the carrier therefore cannot ascertain the temperature of the milk at the time it is shipped. And the court suggests that on the record before it, it must be held that the provision here in question of this ordinance, so far as it applies to common carriers, is unreasonable and void, though it suggests further that, after the case is sent back to the trial court, if it can be, more proof be presented to show that the ordinance is reasonable on all the questions involved. Notwithstanding divers scientific theories, on subjects of this nature the courts usually defer to the determination and decisions of the proper authorities as to the basis of police regulations, unless such basis is manifestly erroneous. The court realizes how important the question under consideration is to the health of the people of Chicago and the state at large, and it has no hesitation in reaffirming the rules heretofore laid down by it with reference to the right of the authorities of the city of Chicago to make all proper and reasonable regulations with reference to the care, transportation, sale and delivery of milk in order to protect and promote the health of the people—especially the children—of that city.

Guarding Against Typhoid Fever—May Require Blood Test of Milk Dealers

(People ex rel. Schulz vs. Hamilton et al. (N. Y.), 161 N. Y. Supp. 425)

The Supreme Court of New York, special term, Monroe County, per Justice Rodenbeck, denied an application for a writ of mandamus to the commissioner of public safety of the city of Rochester and others to compel the issuance of a license to the relator to sell milk, after he had refused to submit to a blood test to determine whether or not he had typhoid fever and was a carrier of typhoid germs. The court says that the condition of the public health of the city at the time with respect to typhoid fever was not abnormal, and still the requirement of a blood test as a condition for a license to sell milk and cream seemed to be a fair and reasonable precaution, to protect the public against any increase of typhoid. Milk is a peculiarly sensitive product, produced under conditions which, if not regulated and controlled, may carry and disseminate the germs of typhoid or other diseases and spread them in the community. It is the chief food of infants, and lies at the basis of their health and strength. It may be heated, sterilized or pasteurized, but even then contact with unclean utensils or unclean human beings may make it the carrier of disease germs. Unlike other articles of food, it cannot be washed and otherwise cleansed in the home. The impurities may be hidden from sight, and thus a sense of security engendered which may render it a still more serious menace to health. Under these conditions it would seem to impose no unreasonable hardship on a dealer in milk or cream to require him to submit to a blood test, to make sure that he has not had typhoid and is not a typhoid carrier. That typhoid fever is a contagious disease and may be transmitted by one afflicted with the disease is a matter of common knowledge, and the court will take notice of that fact without proof. The court will also take notice of the fact that an examination of a drop of blood will reveal whether or not the person from whom it has been taken has had typhoid. This may not be universally held by scientific men or universally believed by the people, but, until science disproves the value of the test, it will be accepted by the courts as true. The imposition of this test with respect to this particular occupation, and the requirement of this and any other test in any other occupation which may affect the public health rests in the sound discretion of the state or local authorities in whom the discretion to pass on the subject has been vested. This rule does not infringe on the civil rights of the individual. Government has been instituted among men for their mutual protection, and no man has the right to make himself or his business a menace to the public health. It is important to the whole community that the supply of milk and cream should be kept clean, pure and wholesome and should not be contaminated with impurities, or infected with disease, and it is the duty of the health authorities to see that this is accomplished by the establishment of such reasonable regulations as may be necessary to meet existing conditions or to ward off impending dangers to the public health, and in imposing a blood test as a condition to a license to sell milk and cream in the city, the commissioner of public safety and the health officer acted within the scope of their authority, and applicants for such a license should cooperate with the public authorities, and assist, rather than oppose, reasonable efforts to provide pure and wholesome milk and cream for the people of the city. The requirement of a blood test of an applicant for a license is just a step, and a small one, in the direction of the protection of the public health, but every reasonable effort made in this direction should be encouraged, so long as it does not unreasonably infringe on the rights of the individual. The court holds, too, that the health authorities of the city are not required to wait until an epidemic of typhoid has broken out before taking precautions against it, but in the exercise of a reasonable judgment may anticipate such a condition, and may and should make all reasonable efforts to perform the duty imposed on them by statute and to take all reasonable precautions to protect the public health before the emergency arises.

ANNUAL CONGRESS ON MEDICAL EDUCATION, PUBLIC HEALTH AND MEDICAL LICENSURE

THIRTEENTH ANNUAL CONFERENCE OF THE COUNCIL ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION

Held in Chicago, Feb. 5, 1917

Dr. Arthur Dean Bevan, Chicago, in the Chair

Progress of the Year in Medical Education

Dr. N. P. Colwell, Chicago: The requirement of two years of college work for admission to medical colleges is reasonable, and the action taken by the House of Delegates last June in making that standard a requisite for the Class A rating was not drastic. This is indicated by the fact that at that time fifty-one medical colleges and sixteen licensing boards had already adopted that standard. At present sixty-five medical schools and nineteen state licensing boards have adopted two years of college work as the minimum standard of preliminary education.

A clause in the recommendation adopted by the House of Delegates stated that the colleges of arts and sciences in which the two years of college work were to be obtained should be "approved by the Council on Medical Education." This made it the duty of the Council to prepare a list of approved colleges. The Council has secured lists of those approved by various standardizing agencies such as the Association of American Universities, and the North-Central and Southern Associations of Colleges and Secondary Schools and by leading universities.

The House of Delegates also instructed the Council to cooperate with other educational organizations in an endeavor to save one or two years of the student's time during the course of his preliminary or medical education. For the present session of the medical schools from which reports have been obtained a large majority show increases in the enrolment of students in freshmen classes. Although the total number of medical schools has been reduced by over 40 per cent. in the last twelve years, the number of colleges having improved educational standards has been increased by over 95 per cent. The numbers of medical students and medical graduates from these high standard colleges have been increased in about the same proportion.

One of the most satisfactory accomplishments of the Council has been the development of the medical students' register, which was started in 1910. In that work from the beginning the Council has had the cooperation of a large majority of the medical schools, which have furnished intricate and detailed reports regarding the new students enrolled each session. In addition, the colleges have sent reports from the individual students giving their educational histories up to the time they entered medical school.

Attention was called a year ago to clauses in the medical practice acts of the Canadian provinces of Ontario and Quebec discriminating against medical schools of the United States. Correspondence with officials in Ontario has resulted favorably and the discriminatory clause has been stricken out. With the Province of Quebec, however, the practice act still requires that before a graduate of any medical school in the United States can secure registration in that province he must follow the last year of the medical course in one of the schools of medicine of Quebec.

A year ago attention was called to the lack of safeguards in the chartering of educational institutions in the various states. Correspondence has since been carried on with superintendents of public instruction, presidents of state universities, secretaries of state medical licensing boards and officers of state medical societies calling attention to that need and urging the securing of better legislation. As the correspondence progressed it was ascertained that any legislation regulating the chartering of educational institutions should contain the following provisions: (*a*) restrictions in the use by any person, organization or corporation of the terms "school," "academy," "college" and "university"; (*b*) educational standards which should be met by institutions seeking the right to grant degrees before a charter is issued; (*c*) revocation of the charter of any institution which is found to lack the needed equipment or teachers, which may be found to be using fraudulent methods or which for other reasons is not living up to the standards fixed by the state; (*d*) a state board, commission or other body which would have in charge the regulation of such institutions as have been chartered, and (*e*) ample funds for effectively carrying out the provisions of the law.

The objection to medical cults is their lack of adequate education. Any one having to do with the treatment of human diseases needs to have a sufficiently thorough training to be able to recognize the disease he is attempting to treat; otherwise his treatment is unscientific and as liable to do harm as good. A training in the fundamental sciences is needed, no matter whether drugs are employed or not and no matter what system or method of treatment may be used.

The educational standard adopted in all leading nations as the reasonable minimum standard for practitioners of the healing art includes: (*a*) a secondary school course equivalent to that of the better high schools of this country and in addition the completion of one or two years of work in a college of liberal arts, including courses in physics, chemistry and biology; (*b*) a thorough medical training provided by a four year course in a well equipped medical college including two years in the laboratories of anatomy, physiology, bacteriology, pathology, pharmacology and physiologic chemistry, and two years in clinical instruction in dispensaries and hospitals, and (*c*) the practical experience obtained in a fifth year spent as an intern in a good hospital.

The Problem of Higher Degrees in Medicine

Dr. Horace D. Arnold, Dean Harvard Graduate School of Medicine, Boston: Opportunities for advanced study and research have long been offered by medical schools, yet the problem of higher degrees in medicine has arisen only recently. Degrees for the recognition of advanced scholarship are sanctioned by our best universities and help to establish and maintain high standards of scholarship. Medicine is undoubtedly a proper field of learning in which to grant advanced degrees.

The existing degrees of B.A. and B.S., M.A. and M.S. and Ph.D. are comparatively satisfactory. The curriculum of a professional school is on the same relative level as the collegiate course, in that it properly leads to a baccalaureate degree, e. g., LL.B., B.D. A bachelor who completes such a curriculum should receive a second baccalaureate degree rather than a master's degree or any other higher degree. Medicine is an exception to this rule, as the regular medical course leads to the degree of Doctor of Medicine, instead of Bachelor of Medicine. This custom has become so firmly established in practice that it must be regarded as permanent, and it is not practicable to change from M.D. to M.B. The problem of higher degrees in medicine is complicated, therefore, by the fact that the doctorate degree is conferred after a course properly leading to a bachelor's degree.

In some instances the degree of Doctor of Science, Sc.D., has been utilized, but this is undesirable, since that degree is used much more commonly as an honorary and not as an earned degree. The use of the Sc.D. degree with mention of the professional field, D.S.Med., D.S.Jur., D.S.Theol., D.S.Eng., has been suggested as the best way of recognizing advanced research in the various professions.

As an advanced degree with less exacting requirements, the Master of the Science of Medicine, M.S.Med., is suggested. The Master of Science without designation of field is conferred after the attainment of B.A., B.S. or an equivalent degree, and, therefore, would not be satisfactory after the attainment of the M D

Professional study beyond that corresponding to a master's degree might lead to a practitioner's degree, types of which are found in the engineering profession, such as Civil Engineer and Mechanical Engineer The call for such a degree in medicine is indicated by the recent efforts to establish suitable standards for specialists by the American College of Surgeons the societies in ophthalmology and other societies of specialists

DISCUSSION

Dr Victor C Vaughan Ann Arbor, Mich The multiplication of degrees is something that should be avoided so far as possible There are already too many degrees The Master's degree as a graduate degree in literary colleges is a joke While as a rule it is not a disgrace, it is at least no honor to have it With these postgraduate degrees there is always a tendency to keep the student in the school where he obtained his undergraduate work Some years ago we tried to encourage the migration of students so that a student could spend one year in one college, another year in some other university and so on A man who has had four years as an undergraduate in a medical school, in getting his clinical work should go to other medical schools so as to come in contact with different men Examinations are a necessary evil and I do not see how we can get rid of them They interfere with a man's originality and with his research work They constantly loom up before him as a specter The National Board of Medical Examiners has set a high standard, and the passing of its examination ought to be equivalent probably to the highest medical degree obtainable in this country The board does not want ordinary students, but does want the six or eight best students in every class after they have had a hospital year

Harry Pratt Judson President University of Chicago The multiplying of degrees will not help us much A man should be known by what he has accomplished rather than by the degrees he has obtained One man may be eminent in medicine and another in research work yet both may hold the same degree, they are known by what they do rather than by the degree they hold A simple solution of the problem would be to give the degree of Doctor of Philosophy It does not matter whether a man is a specialist in mathematics or specialist in pathology, it is all the same so far as the degree goes

Dr Horace D Arnold, Boston The Council's chief object is to establish some means of standardizing the best medical men I know of nothing more likely to raise the public estimate of the medical profession than to have it recognized by universities as on the same high plane as the arts and some of the sciences which would be the case if its eminent specialists were granted the degree of Doctor of Philosophy

Dr Arthur Dean Bevan Chicago It is the function of universities to determine this matter, and the Council may give them the point of view of the medical profession The Chair desires to appoint the following special committee to investigate and report on this subject Dr Horace D Arnold, Boston, chairman Dr N P Colwell, Chicago secretary, Dr L B Wilson Rochester Minn, Dr Isadore Dyer New Orleans, Dr John M Dodson Chicago, Dr William Pepper, Philadelphia Dr Victor C Vaughan, Ann Arbor, Mich, Dr J M T Finney Baltimore, Dr Edward Jackson, Denver, and Dr James Ewing New York

Economy of Time in Preliminary and Medical Education

Dr Arthur Dean Bevan Chicago A study of conditions in Germany and England shows that in countries abroad a student goes from the secondary school direct to the medical department of the university in Germany at the age of 19 and in England somewhere between 17 and 20 In this country the requirements of preliminary education have been gradually raised until the accepted American standard is two years of college work including the sciences preliminary to medical education As a result, medical graduates, after completing their hospital intern year, are 28 years of age on the average, whereas in Germany and England the average is from 25 to 26 years

It is not in the interests of national efficiency for us to graduate our men in medicine two years later than is done in England and Germany Men at the younger age are more eager, more plastic, and have greater possibilities of a future than men graduating two, three or four years later This points clearly to the desirability of reorganizing our scheme of education so as to save two or three years of the student's time

A conclusion forced on me has been the little excuse for the four year college course that is sandwiched in between the high school and the university without definite aim or purpose Nothing like this has developed in any other country It has been demonstrated that two years of special technical training in sciences after leaving high school is sufficient for admission to the medical school The investigation made shows that even with this saving of two years of time as compared with the full college course, the length of time required to complete the premedical and medical training is too great by at least two years, and that some rearrangement should be made in the primary school, in the high school or elsewhere, in order to reduce the time required

Economy of Time in Preliminary and Medical Education

Hon P P Claxton, United States Commissioner of Education Washington, D C The high average age at which students begin their medical studies in this country is due to several causes Many students pay their way through high school and college by going to school a year or two and then working one or more years for money with which to pay their school bills Then after graduating from college they may teach one or more years before beginning to study medicine The older age raises considerably the average age of all professional students and graduates

Another important cause is the shortness of the school year The usual length of the school year in American cities is less than 175 days after holidays are counted out, and the length of the average school day is five hours In rural schools the average school year is from ten to seventy days shorter than in cities the average difference being nearly forty days between city and country schools In western European countries, in Canada, Australia New Zealand and Japan, the school year is from 220 to 250 days The principle of short hours for efficiency is no doubt correct in a measure, but we have carried the matter to an extreme, especially as it applies to the school year

Another cause is irregular attendance There are still states without compulsory school attendance laws, and in none of our states or cities are the attendance laws as rigidly enforced as in most European countries The average daily attendance in our schools is not more than 70 per cent of the enrolment, which means that an average of thirty out of a hundred enrolled are out of school daily Then there is the lack of definite education and professional preparation on the part of teachers In the rural schools a large proportion of the teachers are young and inexperienced The average term of service does not exceed probably five years The constant changing of teachers is another cause Children in our schools change teachers so often that all continuity of study and teaching is lost Then there is the lack of definite organization of courses of study, but most of the time lost in American schools is probably through the long drawn out elementary courses running through eight years and continuing two or three years after the beginning of adolescence and the consequent postponement of the time of beginning high school subjects, by the attempt to crowd all secondary work into four years, and by a false policy in college administration which fails to make the first two years of college life as effective as they might be

European countries gain much for the children of the upper classes and for all who are looking forward to the university and professional studies in life by making their secondary schools—the gymnasium, the realschule, the lycee, English public schools, etc—to parallel their elementary schools in time rather than to follow them

I should strenuously oppose any scheme for the reorganization of public education in this country based on class distinctions I should oppose also any dual system of schools

I believe in our democratic tandem system of elementary and secondary schools, but I believe it is possible to make a much better arrangement and use than we now do of twelve years' elementary and secondary schooling

DISCUSSION

Harry Pratt Judson, President, University of Chicago The age at which students on the whole receive their M D degree is too advanced, and the causes are perfectly obvious One is the utterly unrelated character of our American educational system Every branch today is considered separate from everything else Those in charge of medical education have steadily advanced the requirements for beginning medical work wisely and advisedly Those entrusted with our colleges have and will advance their requirements for admission In secondary schools, many subjects are taught which were not thought of a generation ago In like manner, elementary schools have many studies which a generation ago were not heard of Unfortunately there has been no correlative force in this country to view education as a whole or to bring it together in a systematic or coherent way I believe the elementary school work can be covered in six, or at least in seven years, because we have tried and found that it can be done We can save not only one year in this way, but ultimately, I believe two years What we need is a complete, drastic reorganization of our whole system of education involved in colleges and secondary schools preceding the professional work It is not so much a knowledge of different things that students need, but a better training of the mind

C H Judd, Professor of Education, University of Chicago We need the cooperation and intelligent sympathy of the community When a school man starts to work out these reorganizations he commonly finds he is definitely opposed by the community It is difficult to make the changes suggested when it comes to their administration In the University of Chicago we have eliminated the eighth grade in the elementary school, but it was opposed by some of the patrons of the institution There is a general movement at the present time in the United States toward the organization of what is known as the junior high school, but this is opposed in many quarters as an innovation inimical to the development of our American educational progress

Thirty per cent of our colleges today are going out of business, and the expansion of secondary schools has been enormous In the last twenty-five years we have twice doubled the total population in our secondary schools In 1890 there were 300 000 students in secondary schools, this year there were 1 300 000 students It necessitates a complete reorganization of the elementary and secondary schools and the subjects taught and by means of the junior high school there will be a welding together of the schools, which is of great importance We need sufficient backing to carry the work out and to articulate the junior college with the high school With the proper reorganization we could develop a satisfactory American system of education

Kendric C Babcock Dean College of Liberal Arts and Sciences University of Illinois All who have watched higher education and secondary education as connected with it agree that much time is wasted and that we should proceed at once to save as much of that time as possible Doctors and educators are not agreed as to how that saving should be made One reason for students getting their M D degree at an advanced age is the tendency of youngsters to change their minds After spending four years in a high school many do not want to pay the price of changing their minds Many students in the premedical course have gone over to law or to some other subject and afterward taken up medicine

Dr George Royal Des Moines, Iowa The new president in the University of Michigan has gathered statistics showing what effect university training has had on students He found that the really successful or prominent men were those who graduated at 22 and 23 and that those who graduated at 25 or later were not, as a rule, so successful Two years can be saved before students reach the medical college

Dr. H Gideon Wells Chicago The University of Chicago has a quarterly system which permits a student to work eleven months in the year instead of nine, which enables him to do more work, although it does not shorten the period at which he may graduate

Dr S B McCormick, Pittsburgh It is necessary to educate the people in regard to this plan of saving one or two years' time in preliminary studies The time is coming when many institutions which are now colleges will become junior colleges and be incorporated under the general public system of education If we have cooperation, we shall ultimately eliminate much of the waste of time

Mr Augustus A Downing, Albany N Y I consider it a crime against the child and against the community to turn a child lose from the elementary school and high school at the end of June and let them go anywhere and everywhere until the first of September They would be better off if the school term were materially lengthened

(To be continued)

NEW YORK ACADEMY OF MEDICINE

Meeting held Jan 18 1917

Dr Edward D Fisher in the Chair

Etiology of Typhus Fever in Mexico

Drs P K Olitsky, B S Denzer and C E Husk This report presents the results of an expedition into Mexico during the early part of 1916 for the purpose of studying typhus fever The work was done in Matehuala Central Mexico, a town of 10 000, in which the estimated number of cases during the winter months was 500 The mortality was 20 per cent Clinically, the disease corresponded to the classical type The scientific work consisted in virus and bacteriologic studies serologic tests work on the pathogenicity of the organism recovered from the blood, and prophylactic inoculation with a vaccine made from the *Bacillus typhi-exanthematici* The virus studies confirmed previous observations that the blood of typhus fever patients removed during the height of the disease and injected into guinea-pigs produces a rise in temperature of from four to eleven days duration after the incubation period of from seven to fourteen days The Mexican virus was transmitted in this manner through three generations of animals Blood cultures were taken in thirty-one cases and numerous controls The technic and mediums employed were those used in the original studies in New York in 1914 except in three cases Of the twenty-eight cultures made on 2 per cent glucose serum agar only eight could be followed a sufficiently long time These eight cultures showed an organism identical with that first isolated and described by Plotz in 1914 Agglutination tests performed on the serum of typhus fever patients with the *Bacillus typhi-exanthematici* confirmed the previous findings The organism obtained from the blood, as well as that isolated from lice was identified by its morphologic and cultural characteristics and serologic reactions The organism is a slender bacillus about 1 micron in length usually gram-positive, although many strains are gram-positive It is an obligatory anaerobe, and grows sparsely on 0 5 per cent serum glucose agar, it ferments glucose, maltose inulin and galactose, and fails to ferment lactose, mannite and saccharose Agglutination, using endemic typhus serum against Mexican strains, showed positive reactions in four out of five of those tested In like manner, complement fixation tests against typhus immune serum showed uniformly positive results, and uniformly negative results with nontyphus serum In a word there is a complete correspondence culturally and serologically of the Mexican organism with the bacillus of Plotz Experiments on guinea-pigs indicated that the organism is pathogenic for this animal in the original culture, and loses its virulence on repeated cultivation

Isolation of the Bacillus Typhi-Exanthematici from the Body Louse

Drs P K Olitsky, B S Denzer and C E Husk Up to the time of the Mexican expedition all cultural work proved fruitless One of the results of the expedition was the finding of the same organism in infected lice which Plotz reported as the etiologic agent of typhus fever The work in Mexico on typhus-infected lice may be grouped into (1) the production of typhus fever by the injection of infected lice and (2) the isolation of the typhus bacillus from such lice In two instances the injection of thirty and sixty-five lice, respectively, intraperitoneally into guinea-pigs led to the production of typhus fever In the one case cultured the typhus bacillus was recovered from the spleen of the guinea-pig Six series of lice taken from five different typhus patients were cultured From all of these lice, the typhus bacillus was isolated In all the experiments made, these lice were proved infectious A striking observation was that these organisms are usually gram-negative in the original colonies After one or two subcultures they become definitely gram-positive Since 1910 many observers have reported the finding of an organism in typhus-infected lice but not in normal lice This organism is believed to have a causal relationship to typhus fever In Mexico we were able to grow the bacterium and to show that morphologically, culturally and serologically it is identical with the typhus bacillus

Etiology and Epidemiology of the Typhus Fever of Eastern Europe

Drs G Baehr and H Plotz The bacteriologic studies made on sixty-four individuals with the disease demonstrated that the *Bacillus typhi-exanthematici* is regularly present in the blood of people suffering from the typhus fever of eastern Europe In Volhynia anaerobic blood cultures were positive in nineteen out of twenty-four cases, or 79 per cent of the cases studied In the Balkans, where blood cultures often could not be placed in an incubator until four or five days after they were taken, the percentage was lower, 47 5 The relative bacteremia was also proportional to the severity of the disease For example, in the Russian typhus in which the mortality was 5 5 per cent and in the Balkan 1915-1916 typhus in which it was 11 per cent, the bacteremia was greater than in the New York series in which the mortality was negligible, 0 2 per cent , it was much less than in the Mexican typhus (mortality about 20 per cent) or the severe Balkan type of the disease (mortality from 18 to 60 per cent) It was found, furthermore, that during chills enormous numbers of organisms may be present in the blood, the maximum being 1,183 colonies in 13 c c of blood Morphologically, culturally and serologically, the organisms recovered from these Russian and Balkan patients were identical with those originally recovered in the New York cases The *Bacillus typhi-exanthematici* has therefore now been recovered by the authors and others from typhus fever patients in the United States Mexico Serbia, Bulgaria, Austria and Russia The maximum titer of agglutinins for *Bacillus typhi-exanthematici* in the blood of the cases studied was 1 1,600, the average was 1 200 As a result of systematic studies carried out in 100 cases of typhus fever, it was found that agglutinins usually first appear in the blood on about the tenth or eleventh day of the disease or at about the time when the temperature begins to break The agglutinin titer of the serum then rapidly increases as the temperature drops to normal, and reaches its maximum toward the end of the first or the beginning of the second week of convalescence At this time 97 per cent of the serums were positive After this time the agglutinins diminish in amount very slowly, and usually persist in the blood for many months The curve of the development of specific agglutinins in typhus fever is therefore a typical immunity curve During the course of the work, specific agglutinins and complement-fixing antibodies were found in the blood of twenty normal persons, in amounts otherwise observed only in convalescents from typhus fever None of these persons had ever shown any clinical manifestations of typhus fever These twenty patients were either physicians, nurses or male attendants in typhus hospitals in which they were constantly handling typhus patients, or they were peasants who had been living with relatives or friends ill with the disease As these twenty contacts were the only persons, aside from typhus convalescents, in whom such findings were made, it was reasonable to assume that during the time of their exposure to typhus fever they had actually been infected with the bacilli in quantities sufficient to induce the clinical manifestations of the disease, and had reacted with the production of specific antibodies Such persons, who have probably become immune without having the disease, may act as carriers of infected lice and be agents of their distribution throughout a community

Studies in Prophylactic Immunization with the Bacillus Typhi-Exanthematici

Drs H Plotz, P K Olitsky and G Baehr Vaccination was carried out in Serbia, Bulgaria, Russia and Mexico during the winter of 1915-1916 The vaccinations were restricted as far as possible to those persons who were most exposed to infection In addition to the doctors, nurses and orderlies many other hospital units were vaccinated, and in a few instances small military groups The reactions following vaccination were very slight Among the 5,251 vaccinated persons in Bulgaria, there occurred only three cases of typhus fever, one of the patients died After completion of vaccination, although 300 patients were admitted in the subsequent three weeks, no further house infection occurred In Volhynia 3,169 persons in forty-six institutions were vaccinated, and up to May, 1916 there occurred only three cases of typhus fever among those vaccinated About 2,000 were vaccinated in Mexico, but owing to the fact that the men carrying on the work had to leave Mexico, no statistics are as yet available Whatever reports have come from Mexico up to the present time seem to be favorable Altogether 8 420 persons, members of 109 hospital, sanitation and other units in Serbia, Bulgaria and Volhynia were vaccinated during the epidemic of 1915-1916 and only six of this number developed the disease during the four months of the epidemic

DISCUSSION

Dr Gedide A Friedman I have observed typhus fever in Russia during three *epidemics* and I have also *seen many* sporadic cases I was glad to hear a confirmation of the opinion I expressed six years ago about ambulatory typhus cases I have seen such patients over and over again, sometimes with high temperature, who gave a history of having been sick five or six days I was interested to hear of the severe chills which occurred in some of the cases seen in the Balkans It is a peculiar fact that typhus fever manifests itself in the beginning with chills which were not seen in other diseases, except perhaps malaria, and I have seen cases wherein the chills lasted for hours I have occasionally observed chills in children, but very rarely , commonly typhus in children does not begin with a chill, or perhaps a slight chill might be overlooked The mild course of the typhus tabulated in the statistics might be explained by the fact that most of the patients were Jews, and I have emphasied the fact that the course of typhus in some races, such as the Jews and Arabs, was mild and the mortality was not so high as among other races The most severe cases occurred among the Russian peasants As to the body louse being the transmitting agent, I could add from my own experience that this is probably true because typhus is a disease of the poorer classes I have rarely seen it among the well to do

Dr Nathan A Brill There is not the slightest doubt in my mind that the *Bacillus typhi-exanthematici* is the only cause of typhus fever, and that the body louse is the agent of transmission of the epidemic form of the disease to man There is some doubt in my mind whether it is the only agent concerned in the transmission of the endemic form of typhus fever It has been conclusively shown by Nicolle, Anderson and Goldberg that the body louse is rendered inactive by temperatures above 20 C (68 F) that the optimum temperature for its life and activity is between 12 and 14 C (53 6 and 57 2 F), and that it is impossible to keep lice alive in the presence of food in test tubes exposed even to the moderate temperature of the vest pocket The effect of heat on the body louse is utilized by the peons of Mexico, whose important article of dress is the blanket, which is used for all purposes of covering To rid their blankets of lice they expose them to the warm rays of the sun and on shaking them thereafter, the lice thus rendered lethargic fall off and are removed It appears that the body louse is active in cold and inactive in warm temperatures This fact would explain many of the epidemiologic features of *epidemic* typhus fever, a disease chiefly confined to the colder regions of the earth, and when it does occur in the warmer latitudes it is restricted in the main to the highlands where the daily temperature is low All statistics will show, whether you search the English, the German or the Russian, in all of whose countries epidemic typhus fever has repeatedly appeared, that this form of the disease is rampant in the winter and diminished in severity and in the number of infected people as the summer approaches, when it disappears almost entirely When, on the other hand one studies the facts which relate to the endemic form of typhus fever as it existed in New York City, it is found that by far the greatest number of cases of endemic typhus fever occur during the summer months, when according to investigators the body louse is inactive and does not live A study of the statistics dealing with this point shows that 60 per cent of all endemic typhus fever cases occurred in the four summer months, between June and October, while the remaining 40 per cent were distributed over the other eight months of the year, with by far the fewest cases in the winter, the very reverse of the situation as regards the epidemic form of the disease This induces me to believe that either we shall have to modify our views in reference to the effects of temperature on the body louse, which seem fairly well established, or that we shall have to look for some other agent of transmission of the infection in the endemic form of typhus fever Another argument in support of this view is furnished by the fact that house and family infection of the endemic form of this disease practically does not exist In over 400 cases of this form of the disease observed by me I have never seen more than one member of a family affected at even approximately the same time until last spring when the first cases of nearly simultaneous infection of husband and wife were seen in the hospital If the body louse transmits the endemic form of the disease one would expect marital infections to be very common Such infections are extremely rare and practically nil Therefore while I am not prepared to say that the body louse is not an agent in the transmission of endemic typhus fever, I hope to see more positive proof than has been offered that there is no other source and agent of infection in the endemic form of the disease

8 9 10 and 11 Abstracted in The Journal, Nov 4, 1916, p 1392

Cleveland Medical Journal

December 1916, XV, No 12

15 *Pyloric Stenosis in Infancy H G Sloan, Cleveland —p 761
16 Case of Fracture of Base of Skull and Some of Its Characteristic Symptoms A Peskind Cleveland —p 776
17 *Obscure Case of Empyema A Peskind Cleveland —p 788
18 *Fate of Iodin, Iodids and Iodates in Body T Sollmann, Cleveland —p 792
19 Case of Ethmoiditis in Child Complicated by Unilateral Exophthalmus D A Prendergast, Cleveland —p 802

15 **Pyloric Stenosis in Infancy**—Sloan recommends the Rammstedt operation for these cases Vomiting is seen much less than after gastro-enterostomy In case the baby cries for fifteen minutes or over, the author advocates giving paregoric, 30 drops, to keep it quiet during the healing of the wound There is practically no shock when the surgical procedure is carried out on the principles outlined Food is taken as in a normal infant and the weight gain is immediate and progressive So far, literature contains no account of the recurrence of the symptoms following the Rammstedt operation

17 **Case of Empyema**—The most interesting features in Peskind's case was that the child must have originally suffered from a latent pneumonia or pleuropneumonia of the upper right lung, which culminated in a small interlobar encysted empyema, perhaps in the pleuropericordial fold

18 **Iodin, Iodids and Iodates in Body**—The immediate object of Sollmann's investigation was to determine these questions (1) whether the administration of elementary iodin can result in the appearance of iodid and iodate in the blood or tissues, and (2) whether elementary iodin can be liberated from iodid and iodate, combined or separately, with the reaction (hydrogen-ion concentration) that is known to exist in the body The following results were found Tests depending on the liberation of small quantities of iodin cannot be applied to protein-containing fluids or to urine, since considerable iodin is immediately bound by the aromatic radicals Under the conditions used, the amount of iodin bound by serum was about 1 3,000 By the use of the dialysis method it was shown that neither iodid nor iodate undergo any change in the serum Free iodin is promptly bound, with the formation of iodid, but no iodate is formed even in the presence of alkali so that subsequent acidulation does not liberate iodin (unless, of course, more iodin has been added than can be disposed of by the serum) The statements hold also for other proteins, urine and phenol Large doses of free iodin, administered by stomach, exist in the blood solely as iodid The addition of acid to the blood does not regenerate iodin No iodin is liberated from iodid iodate or iodid nitrite, or iodate sulphocyanid mixtures, until the acidity surpasses Hp = 4 49 It is therefore impossible that iodin should be liberated from iodid under any conditions existing in the body (excepting solely the gastric juice) On the other hand, the alkalinity of the body is not sufficient to bind any noticeable quantity of free iodin—even in the absence of proteins and aromatic groups The questions that were proposed are therefore answered in the negative

34 **Venom Hemolysis After Splenectomy**—Since the phenomenon of venom hemolysis appears to be intimately associated with the lecithin or ether soluble activators present in erythrocytes, particularly fatty acids and their soluble soaps, and the removal of the spleen has been shown to alter the content of fatty substances in the blood, the resistance of erythrocytes to venom before and after splenectomy was investigated by Kolmer He found that the resistance of erythrocytes of dogs to the hemolytic activity of cobra venom is increased after splenectomy This increased resistance was observed as early as four days after splenectomy and usually persisted for a period of about three weeks when the resistance gradually decreased to normal or slightly beyond The decrease of resistance to the hemolytic activity of venom for the erythrocytes of splenectomized dogs following the primary increase is apparently coincident with the anemia following splenectomy An intercurrent infection such as distemper, tends to reduce the resistance of erythrocytes to venom An increased resistance of the erythrocytes to hypotonic salt solutions was found with all the splenectomized dogs in which these tests were made Increased resistance to hypotonic salt solutions apparently persists for a longer period than the increased resistance to cobra venom As the lysis of erythrocytes by venom is dependent on the presence of certain lipoidal substances within the cells, and as the spleen may exercise an influence over the lipoidal contents of corpuscles and serum, it is suggested by the author that the increased resistance of erythrocytes to the hemolytic activity of venom after splenectomy is due to alterations in the lipoid content of the erythrocytes

35 **Effects of Serum Treated with Pararabin**—Horse serum, kept for two hours at 38 C in the presence of one fifth its volume of a suspension of 0 5 per cent of pararabin in physiologic salt solution and then freed by means of centrifugalization and filtration from the pararabin, produced, when injected in appropriate doses into a normal rabbit, a considerable and prolonged fall of the blood pressure, a distinct retardation in the coagulation of the carotid blood, and, sometimes, in addition, acceleration of the respiratory rate and the expulsion of numerous scybala, that is, the various symptoms observed to occur after the intravenous injection of horse serum in sero-anaphylactized rabbits If the horse serum is first heated for thirty minutes to 56 C and then treated with pararabin in the manner described above, the intravenous injection of this serum into a normal rabbit exerts no more action on the arterial pressure, the coagulability of the arterial blood the respiratory rate, and the intestinal activity, than does normal horse serum when introduced into the vein of a normal rabbit

36 **Albumin Globulin Ratio in Experimental Intoxications and Infections**—The intoxication which develops as the result of a simple obstruction or a closed intestinal loop is accompanied by an alteration in the normal albumin globulin ratio of the blood serum, the globulin fraction is greatly increased and at times the normal relation of the two fractions may show a complete inversion The increase in the globulin content of the blood serum is most marked in the animals which show some of the complications met with in loop animals rupture of the loop and peritonitis In the latter conditions especially the globulin increase is rapid and large The authors believe this reaction to be of diagnostic value in acute infections attended by the sudden liberation and absorption of a toxic exudate Infections and intoxications produced by inflammatory irritants are also accompanied by a rise in the blood globulins This observation suggests that tissue disintegration with absorption of toxic products is responsible for the changes noted, and that bacterial invasion is important only in so far as it gives rise to toxic substances Animals which have developed a tolerance to proteose intoxication following the periodic injection of small doses of proteose, do not show a globulin increase These experiments do not support the view that the rise in globulins observed in these experimental conditions is an expression of a resistance or tolerance developed by the animal From the experimental evidence it seems more probable that the alteration in the partition of the blood protein fractions is one of the results of the metabolic disturbance which has been shown to occur in these conditions

37 **Nymph and Prosopon of Tsutsugamushi**—Tsutsugamushi or kedani disease is an acute exanthematous infectious disease, which at present occurs only in the northern coast districts of Japan, namely in Niigata ken Akita ken and Yamagata ken Recently it has also been found to exist in Formosa The mortality of the disease varies according to the district and year, between 20 and 50 per cent It closely resembles Rocky Mountain spotted fever, but it possesses some distinct features The specific cause of the disease has not yet been established with certainty That tsutsugamushi disease is transmitted to man by a diminutive mite is now established Brumpt considered it to be a larva of a new trombidium, which he called *Trombidium akamushi* The nymph and the prosopon of the tsutsugamushi, however, do not bite warm blooded animals That the investigation of this mite has so far been neglected is chiefly due to the danger of the bite which causes the disease and to which the investigators are exposed while working in the infected region The authors report on the nymph and the prosopon of the tsutsugamushi

39 **Pancreas Intoxication**—According to Goodpasture a toxic constituent is present in the fresh pancreas of dogs before trypsinogen can have been activated The toxic fraction is present in the betanucleoprotein, and therefore is thermostable It is gradually destroyed by autolysis but can be obtained in concentrated form from a gland which has autolyzed twenty-four hours The toxic material is probably protein in nature Intravenous or intraperitoneal injection of from 0 05 to 0 1 gm per kilogram of body weight is usually fatal and elicits in dogs symptoms comparable to those of spontaneous hemorrhagic necrosis of the pancreas Dog pancreas differs from that of beef or pig in that guanylic acid and toxic protein combined with it are slowly broken down by autolysis After autolysis of dog pancreas the toxic protein and guanylic acid may be separated and obtained in relatively pure form

40 **Changes in Nonpregnant Guinea-Pig**—The authors found that a definite cycle exists in the mammary gland of the nonpregnant guinea-pig which corresponds to the cycle in the ovary and uterus Extirpation of the ovaries prevents not only the proliferation of the mammary gland associated with the first stage of the sexual cycle, but in all probability also

inhibits the proliferation of the mammary gland which occurs under certain conditions toward the end of the sexual cycle, or in instances of experimentally prolonged sexual cycle in which well preserved corpora lutea and deciduomas are present In animals in which the ovaries were hypotypical, the mammary glands were in an inactive condition The presence of hypotypical ovaries has the same influence on the mammary gland as castration Complete extirpation of the corpora lutea seems directly or indirectly to prevent the secondary proliferation of the mammary gland, which occurs during the latter part of the sexual cycle or during an experimentally prolonged cycle, in cases in which the extirpation is not followed at once by a new ovulation In cases in which the whole or almost the whole uterus had been extirpated, the corpora lutea were well preserved and the mammary gland was proliferating

41 **Changes in Pregnant Guinea-Pig**—In the pregnant guinea-pig proliferation of the mammary gland becomes regular only at a later stage of pregnancy, namely, during the period following the twenty-fourth day of pregnancy Previous to this period proliferation was absent in the majority of cases After the completion of pregnancy and in the beginning of secretion some mitotic proliferation may still be present, but it soon ceases Some proliferative stimulus seems still to be active In cases in which abortion took place in the first half of pregnancy, secretion in the gland was not established, secretion occurred in two animals aborting toward the latter part of pregnancy In guinea-pigs castrated during an early period of pregnancy, in which pregnancy continued for some time, proliferative changes were absent in the mammary gland Extirpation of the corpora lutea during pregnancy induces a new ovulation and with it the primary proliferation in the mammary gland, abortion does not necessarily prevent these proliferative changes Five injections of cow s lutein given in relatively large quantities intraperitoneally do not produce proliferation of the mammary gland in the guinea-pig

43 **Epithelial Cells and Saprophytes in Sputum**—Microscopic examination of sputum that has been washed with isotonic salt solution, Otani says indicates its source Sputum from above the vocal cords contains polygonal flat epithelial cells and numerous species of nonpathogenic micro organisms Sputum from below the cords is clear of saprophytes, although it sometimes contains broncho-alveolar cuboidal cells In every instance he found erythrocytes in the pulmonary sputum after severe pulmonary hemorrhage Six cases of laryngeal affection referred to in the paper had had no subjective symptoms, but microscopic examination showed tubercle bacilli in the laryngeal sputum

45 **Salicylate in Blood and Joint Fluid**—The concentration of salicylate in the blood and joint fluid of individuals suffering with rheumatic fever and receiving full therapeutic doses of sodium salicylate was estimated by the authors The results indicate that the concentration of salicylate in both fluids does not differ markedly, being somewhat less on the whole for the joint fluid as might be expected The following average concentrations were found 0 02 per cent for blood and 0 018 per cent for joint fluid The concentration of salicylate tends to be less in the blood of rheumatic than nonrheumatic individuals There was no demonstrable free salicylic acid in the joint fluid of rheumatic fever patients The true reaction and the reserve alkalinity of the blood were not perceptibly altered by the administration of salicylate even in large doses

47 **Pharmacology of Stovain**—Experiments made by Smith and Hatcher afforded no evidence that stovain exerts any direct action on the blood vessels after the intravenous injection in cats, and it failed to change the caliber of the renal vessels of the cat or dog when perfused in concentrations of 1 10,000 to 1 2,500 It depresses the heart when toxic doses are injected intravenously, and when the rabbit's heart is perfused with a solution containing 1 part of the drug in 10,000 parts of Locke's solution Stovain causes death by inducing immediate and simultaneous paralysis of the heart and respiration, the action on each being independent of that on the other Stovain disappears rapidly from the blood stream after its intravenous injection Little or none, of the drug is excreted unchanged in the urine of the cat Stovain is slightly, but distinctly, more toxic than novocain by similar modes of administration, and complete recovery does not follow the administration of toxic doses of stovain so promptly as it does that of corresponding doses of novocain

48 **Elimination of Hexamethylentetramin**—The object of this paper is to show the possible use of hexamethylentetramin as a test for renal function In none of twelve cases diagnosed clinically in general terms as 'nephritis" was any hexamethylentetramin excreted A case diagnosed as 'nephritis and gout" showed results similar to those diagnosed as nephritis Three cases of gout gave normal hexamethylentetramin excretion slightly low dye and high nonprotein nitrogen tests, high uric acid and in two of the three, normal test meal results In two cases diagnosed as cirrhosis of the liver, the excretion of hexamethylentetramin was low or zero The nonprotein nitrogen and uric acid findings were normal but the test meal results showed impairment of kidney function

76 **Surgery of Peripheral Nerves** —Porter studied 187 cases of peripheral nerve lesions In four cases of facial paralysis attempts at suture were made one primary after a razor cut, with unknown result, one six months after a pistol wound suture of the eleventh to the seventh nerve no improvement The third complete paralysis thirteen years after a convulsion The facial was split and a slip of the hypoglossal placed in the niche Fifteen years afterward there is partial recovery In the fourth case, following a mastoid operation two years before the facial was anastomosed to half of the hypoglossal Ten years afterward there are weak voluntary facial movements though faradic response is good In one case of brachial plexus lesion, operated on four months after the accident all of the cords found hopelessly blended in a mass of scars were excised and an entirely new plexus constructed which, Porter says, would defy a professor of anatomy In this case flexion of the wrist first began three years after operation, improvement continued and now, while there is flexion of the arm, wrist and fingers, and some power in the triceps, the extensors are paralyzed

The results after musculospiral paralysis are very satisfactory The nerve has been freed from adhesions or bony callus in eleven cases, with marked improvement in nine failure in one, one not heard from There have been fourteen sutures six have been successful In 1913 Porter transplanted 4 inches of a dog s sciatic between the ends of the nerve There has been no improvement The longest case was one of resuture six years after an unsuccessful union result unknown probably failure One primary suture recovered in eleven months There have been forty-eight cases of suture of the ulnar and median nerves A few of the primary sutures have been almost perfect as has one (3 months old) secondary suture of the ulna in the arm three years after the operation The results of the majority were unsatisfactory though trophic disturbances have usually been prevented Porter has operated three times on the posterior nerve roots for pain never with complete success He is certain that in addition to the division of the roots forming the brachial plexus that the fourth cervical and second dorsal should also be cut Porter sounds a note of warning about tourniquet paralysis A rubber tube should never be used about the midarm Even if the arm is padded the nerve may be crushed against the bone

78 **Resection of Thyroid** —In large, diffuse, simple goiters Pool says, double resection is the procedure which most closely meets all indications It relieves pressure, minimizes danger to parathyroids and recurrent laryngeal nerve provides a sufficiency of thyroid tissue, and ensures symmetry Double resection may be carried out readily with little hemorrhage either by Balfour s method or by the use of a clamp as described, or by a combination of the two methods

79 **Complications of Percy's "Cold Iron" Method** —The authors are convinced from a short experience with Percy s method, that fatalities must have been frequent wherever this method has been used extensively They report two fatal cases The development of a septicemia from the infected tissue at the coagulated area was the cause of death The Percy technic was applied most rigidly Nevertheless, microscopic sections show active uninjured carcinoma respectively four, eight and sixteen days afterward In both cases it was found within 1 centimeter of the previous site of the heating iron The necrotic mass produced by the cautery forms a particularly favorable medium for bacterial growth The organisms may spread to the surrounding tissues or reach the general circulation through the local thrombosed vessels The technic is considered by the authors to be ineffectual in eradicating the carcinoma

83 **Surgery of Bronchiectasis** —Included in Robinson s paper is a report of five complete resections of the lower lobe of the lung with one death Excision of the diseased portion of one lung Robinson says is the only curative treatment of advanced bronchiectasis Medications, inhalations intratracheal injections intratracheal irrigations climatotherapy or vaccines are useless Lung resections should be performed in a two or three stage operation The several stage operation of the rib resection type has been attended, in the author's experience with a 20 per cent mortality The operation of intercostal lobectomy has distinct technical advantages When performed in one stage an undue risk of life is incurred The physiologic advantages of the several stage technic may yet be successfully combined with the technical advantages of the intercostal exposure

86 **Ectopic Pregnancy** —The conclusions reached by Oastler from observation of these cases would seem to be that all subacute ectopic pregnancies should be operated on at once removing from the abdomen the tube affected, the fetus, placenta membranes and blood All acute cases should be operated on at once except cases in extremis In these cases it would seem advisable to wait watching the patient very carefully If no improvement occurs in a very short time operate Two patients of this series bled to death The ovarian artery had ruptured in both One was an interstitial pregnancy As there is no doubt therefore that patients can bleed to death operation must not be delayed too long in waiting for a reaction in these extreme cases The abdominal route was chosen in all these cases and it is undoubtedly the only safe procedure to follow Inasmuch as there were no cases extending to the viability of the child in the series, there will be no discussion of the treatment in this condition

88 **Continuous Drainage for Empyema** —Philips has devised a special cannula which is practically nonobstructible, with which one can drain the pleura through an intercostal space, into an air-tight receptacle Special provision is made for the attachment of a suction pump and a negative pressure manometer This makes it possible to maintain any desired negative pressure in the pleural sac while draining it

90 **New Intramedullary Bone Transplant** —The original feature of this operation is the method of cutting the graft at a distance of about 1 inch from the fracture, so as to leave a complete ring of bone at the fracture end The splint is pressed down into the medullary canal and driven across the line of fracture, so that half of the splint will be in each fragment

8 **Treatment of Acute Bacillary Dysentery**—The treatment given these patients by Fisher was dietetic medicinal and specific Patients are only allowed albumin water barley and lemon water for the first forty-eight hours Coincidentally with the improvement of the general conditions the diet is gradually increased Milk is not allowed except in the form of pudding or custard One dram of magnesium sulphate is given three times a day for the first few days, and then as the stools diminish in frequency and improve in appearance the amount is gradually reduced This applies to practically all cases Rectal lavage with 1 1 000 solution of copper sulphate and mistura simaruba often benefit more chronic cases Reliance is placed on specific treatment namely, multivalent antidysenteric serum Each individual case must be judged on its merits In the more severe cases Fisher injects 80 c c into the flank within a few hours of admission, but generally leaves the milder ones until the following morning, and then may give 40 or 60 c c One large dose of serum is sufficient to cure some cases others though much improved require more, and in these, after waiting forty-eight hours, Fisher gives a further 60 or 80 c c A few of the worst may need a third or even a fourth dose Some of the fulminating variety have been given 140 or 160 c c intravenously within twenty four hours of admission If four doses of 80 c c each spread over a period of six or seven days, have not brought about the desired result, further injections are indicated

9 **Id**—Results have convinced Finlayson that 100 c c antidysenteric serum should be given intravenously without delay followed if considered necessary, by a second dose within twenty four hours After one intravenous injection of 100 c c, subsequent doses may be injected subcutaneously into the axilla infraclavicular space or flank The amount which Finlayson usually gives is 40 c c in the morning or evening In association a mixture containing 1 dram of magnesium sulphate 1 dram of sodium sulphate to half an ounce of water, or 1 ounce of mistura alba is administered hourly or even more frequently, until the motions became pale and watery containing perhaps a few blood stained shreds, the interval between the doses is then lengthened according to the conditions noted The diet in the early stage is restricted to albumin water and barley water, with strained chicken tea and meat juices

11 **Flavine and Brilliant Green in Treatment of Infected Wounds**—Taking the whole of the authors results in conjunction the following points emerge of all the substances examined, the compound flavine stands out as possessing the highest sum of desirable properties for therapeutic purposes, that is, great antiseptic power, along with relative nontoxicity toward phagocytosis and lack of irritating effect on epithelium The triphenylmethane compounds, especially brilliant green and crystal violet, are extremely active in the case of cocci, but toward *B coli* their bactericidal value is considerably lower On the other hand, flavine is much the most potent, of all substances investigated, toward both groups of organisms In the case of *B coli* suspended in serum, flavine is approached only by mercuric chlorid (although the latter is about ten times weaker), but the disadvantage of the mercury salt lies in the serious effect which it has in interfering with phagocytosis When tested on staphylococci, flavine is about twenty times more powerful than mercury perchlorid, and 800 times more powerful than phenol as a bactericide Flavine is diaminomethylacridinium chlorid which was originally prepared by Benda at the desire of Ehrlich, and was found to have a very marked therapeutic effect in trypanosome infections Flavine while of approximately equal antiseptic power to the other acridin compounds, is much less harmful to phagocytosis than the latter It is also less toxic It can be administered intravenously, and does not exert toxic action on any special organ Solutions more concentrated than 1 1 000 should not be administered, however, owing to the danger of causing agglutination of the red blood corpuscles A 1 1,000 solution (equivalent, on the basis of bactericidal concentration to an 80 per cent solution of phenol in the case of staphylococci) has been applied to the surface of wounds without causing pain or local irritation and the skin has not been harmed by its use In addition, there have been no local or general toxic effects, even when quantities of the solution have been kept in contact with the tissues for a considerable time or when injected into the tissues

The authors especially emphasize the possibilities in the direction of prevention of sepsis which would be likely to attend the use of flavine or brilliant green in recent wounds applied during that dangerous period between the infliction of the wound and the establishment of an adequate local defensive mechanism It has become the custom at the outpatient department of the Middlesex Hospital to treat all casualty cases by irrigating with a 1 1,000 solution of flavine, because the conclusion has been justified that a wound so treated will in all probability heal by first intention

12 **Id**—Upward of 150 cases have been treated by Ligat with flavine compounds, about 50 per cent of these being war wounds In the case of suppurating wounds the procedure followed has been to secure adequate drainage by free incision when necessary and then to irrigate with a 1 1,000 solution of the antiseptic in normal saline, finally the wound is covered with gauze soaked in the solution, and protective applied to prevent evaporation In case there has been a cavity it has been packed lightly with gauze soaked in the solution A considerable diminution in the discharge of pus may be expected at the end of twenty-four hours In wounds of moderate severity in which no foreign body is present and in which free drainage is secured the suppurative process may be expected to come to an end after four or five days treatment Any difficulty in obtaining free access for the antiseptic to the infected area was overcome so far as possible by syringing the solution into the wound cavity under slight pressure and in some cases flavine 1 1 000 was injected into the tissues and muscle planes by a cannula, no subsequent damage to the parts was observed Ligat has used considerable quantities both of brilliant green and flavine over prolonged periods in some cases injecting the latter antiseptic into the tissues He has never observed any toxic phenomena following their use

16 **Home-Made Bread Substitutes for Diabetic Patients**—Nicholson uses a bread made of peanut flour and casein It has the advantage of being very nice to the taste and can be cut readily into slices even as thin white bread The formula for making it is as follows peanut flour 8 ounces, casein 2 ounces a pinch of salt white of eggs 12 ounces The white of egg is beaten to a snow and then the other ingredients (previously lightly mixed) are slowly added The bread is baked in a sound oven in a tin

32 *Case of Traumatic Rupture of Jejunum, Operation Recovery W S *Handley —p 109*

24 **Hemiplegia Caused by Embolism Following Gunshot Wounds of Carotid Arteries** —In each of the four cases cited by Colledge and Dunn the hemiplegia and cerebral disturbance were caused by occlusion of the middle cerebral artery or its branches In all four there was thrombus present in the carotid arteries in the neck, consequent on damage of the arterial walls and in each there were several inches of the internal carotid artery patent between that thrombus and the portion blocking the cerebral vessel Consequently the authors believe it justifiable to conclude that the blood continued to flow for a time, at least, in the wounded vessels, and that the occlusion of the cerebral arteries occurred by embolism Similar emboli were found in one instance in the branches of the external carotid also The damage to the large cervical arteries was in every case considerable In three there was actual perforation of the wall, in the fourth the trunk was found completely severed, but this, no doubt occurred secondarily by sloughing, after the vessel was fully thrombosed Hemorrhage was slight in these cases, in only one of them was ligature necessary The early appearance and completeness of the hemiplegia and the rapidly fatal issue in these cases—fifteen to seventy-two hours—resemble the effects of ligature of the common carotid

25 **Accessory Bacteria Food Factor in Nasal Secretion** —In dealing with numbers of cerebrospinal fever contacts Shearer noticed that the growth of the meningococcus was in some instances strongly influenced by the amount of nasal secretion transferred by the swab to the surface of the culture medium It was found from experiment that if a trace of dilute sterile nasal secretion was added to the surface of the culture medium, it brought about a rapid growth of the meningococcus when this medium was subsequently inoculated with this germ The growth is always many times the amount obtained on the same medium on planting out a similar quantity of culture in the absence of nasal secretion Shearer suggests that the action of sterile dilute nasal secretion in accelerating the growth of the meningococcus would seem to be entirely in the nature of an accessory food body or vitamin, as alone this secretion is quite incapable of supporting or stimulating the growth of this germ This conclusion is supported by its properties In addition to the meningococcus and its allies, it has been shown to accelerate the growth of the pneumococcus, *B typhosus, B coli-communis,* various fecal streptococci and a number of throat bacteria

29 **Laminectomy in Gunshot Injuries of Spinal Cord** —Symonds advocates using the old term "trepanning the spine" instead of laminectomy He reports cases and discusses their treatment

32 **Traumatic Rupture of Jejunum** —Handley's patient sustained a complete rupture of the jejunum from an accident, the wheel of an automobile passing over her abdomen 6 inches below the duodenojejunal flexure, the small intestine was found to be torn completely across An end-to end anastomosis was done The incision was closed after washing out the abdomen in every part with a large quantity of saline and introducing a pelvic drainage tube just above the pubes A considerable quantity of intestinal contents was found to be present in the pelvis The after-treatment included starvation diet for some days The patient made a complete and rapid recovery Solid food was first permitted about a fortnight after the operation Handley believes the favorable result of the case is largely to be attributed to his abstention from resection

Annales de Mêdecine, Paris

33 *Idiopathic Dilatation of Bladder or Other Urinary Organs (La megavessie et l hydronephrose essentielle.) L Bard (Geneva) —p 567
34 *The Urologic Syndrome with Epidemic Cerebrospinal Meningitis II (Syndrome urologique de la meningite cerebro spinale a meningocoque de Weichselbaum) P Cazamian —p 576
35 Disturbances in Sweat Secretion with Lesions of Peripheral Nerves from War Wounds (Les troubles de la secretion sudorale dans les lesions des nerfs peripheriques par blessures de guerre) A Porak —p 596
36 War Psychoneuroses II G Roussy and J Lhermitte —p 619

33 **Idiopathic Dilatation of Parts of Urinary Apparatus** —Bard insists that essential and progressive dilatation of an organ is essentially the same process wherever it occurs, although the symptoms caused by the different organs involved vary so widely The trouble is some original local subnormal condition rendering it less resistant at this point to the normal pressure which the organ creates or undergoes from the fact of its own physiology He has published four previous studies of this idiopathic dilatation as affecting the glandular organs the alimentary canal, and the eyeball, and he here describes three cases in which the urinary apparatus was involved This idiopathic dilatation wherever it occurs is distinguished by the congenital origin, its development without apparent cause, the long tolerance, and the progressive evolution The recognition of the true cause of the symptoms permits rational treatment, by shutting off the organ if it can be spared and if not, by checking the further development by relieving the organ from all possible strain He states "The polycystic kidney is the manifestation of the trouble when it affects the glomerular-tubuli apparatus, but megabladder, megapelvis, and the more generalized form cystohydronephrosis, are likewise tangible evidence of this anomaly" He had one patient succumb to uremia from the last mentioned cause, nearly the entire urinary apparatus showing this progressive dilatation with secondary atrophy of the kidneys Nothing was found, even postmortem to explain the disturbances otherwise There was no edema till the last month The urine then contained from 1 to 3 gm albumin but no tube-casts The eye fundus seemed to be normal and the heart was not hypertrophied Micturition was inclined to be frequent and scanty His second patient was a man of 48 who succumbed to sudden cerebral hemorrhage after a few weeks of slight albuminuria and symptoms vaguely suggesting a cerebral tumor The bladder ureters pelvis and calices were found at necropsy very much dilated What was left of the kidney tissue seemed normal, as also the urethra

The remembrance of these cases enabled him to diagnose this condition in the third patient, a farmer of 56, who for several months had suffered from headache, nausea and visual disturbance with other signs suggesting uremia from chronic epithelial nephritis Palpation of the abdomen revealed a very large bladder, reaching to the umbilicus, but not causing any discomfort and there was nothing to suggest bladder or prostate trouble otherwise Micturition had been abnormally frequent day and night since childhood, but this pollakiuria had never been regarded as pathologic The desires were urgent but the amount of urine was small each time Acute pericarditis soon complicated the clinical picture, and necropsy confirmed the megabladder and the epithelial nephritis, but there was no hydronephrosis, simple stasis from idiopathic dilatation having evidently sufficed to induce the latent retention with advanced uremia, just as occurs with stricture or a prostatic obstacle Discovery of the megabladder may give the clue to the nature of the kidney trouble, but when the hydronephrosis exists alone, differentiation is dificult (Bard's study of infantile glaucoma as a manifestation of this tendency to idiopathic dilatations was summarized in these columns, April 8 1916, p 1172)

34 **The Urologic Findings in Epidemic Meningitis**—Cazamian regards the polyuria in epidemic meningitis as the reflection from a polydipsia of central origin as the disease takes a turn for the better He continues his study of the subject reporting here the findings as to specific gravity reaction color, aspect and odor, and content in the normal constituents of the urine The curves of their elimination run closely parallel rising under the influence of serotherapy as convalescence approaches Only the urates may show some variability It is evident he thinks that the toxins of the disease, acting on the nerve centers first check and then stimulate the elimination of these substances the latter phase being responsible for the meningitic diabetes" to which Loeper has called attention Cazamian is now studying the elimination of abnormal constituents of the urine and will report later

39 *Requirement of Nitrogenous Foods in the Diet The Meat Question (Besoins de la France en azotes Question de la viande) E Maurel —p 42

40 Malaria in the Wounded from the Eastern Fighting Line (Paludisme et traumatisme chez les blesses de l'armee d Orient) L Moreau —p 48

41 Injury of the Ear from Explosions (Les mutilations de l organe auditif par les detonations Comment peut on les guerir?) Wicart —p 51

39 **Requirements of Nitrogenous Foods**—Maurel reaffirms that while nitrogenous foods are indispensable yet all the different nitrogenous foods can replace each other, weight by weight Whether they are of animal or vegetable origin is practically immaterial The intake of nitrogenous substances should conform to the amount used up and cast off in the vital processes An excess is as bad, if not worse than a deficit The average normal requirement is from 1 25 to 1 5 gm nitrogenous elements in a total of 35 calories per kilogram of the body weight He cites statistics which show that at Paris and Toulouse, about the largest meat-eating centers in France, during the last few years before the war, the daily amount of meat consumed per capita was 170 and 149 gm , representing only 30 and 27 gm nitrogen, that is, only about a third of the requisite nitrogen, and only a sixth and an eighth of the calories required The balance was made up with nitrogenous bodies from vegetables and fruit sources By drawing on these sources still more, the high cost of living can be materially reduced

47 Experimental Research on Treatment of Tetanus J Camus —p 24

48 *Treatment of Superficial Infectious Processes (Traitement des dermo epidermites microbiennes) H Gougerot —p 28

42 **Intravenous Injections of Quinin**—Carnot commends the intravenous route as simple and not at all dangerous, with the customary technic when it is a question of striking quick and striking hard The sterilizing effect of the quinin is reenforced by this route but even this is not effectual against the more resistant forms of the hematozoon the crescents in particular Only with series of partial sterilization are we able to cope with rebellious malaria, and periods of complete suspension are advisable to allow a new crop of the parasites to develop which may prove less resistant

43 **Treatment of Diphtheria Bacilli Carriers**—Labbe and Canat report very favorable results from insufflation of a powder made from the serum of horses previously injected with diphtheria bacilli killed by heat This powder was insufflated into each nostril of the diphtheria carriers four times a day One teaspoonful of the powder in the atomizer bottle serves for thirty insufflations In parallel series of patients treated this way and with ordinary antiseptic measures no diphtheria bacilli were to be found in thirty-five after an average of twenty-four days with the powder treatment while the intervals averaged over forty days in the other group The powder can also be used in tablet form

44 **Sciatic Paralysis After Intragluteal Injections of Quinin**—Sicard and his co workers state that in the last few weeks they have encountered ten cases of extremely painful sensory disturbances in the domain of the sciatic nerve with almost total paralysis of the leg—all the result of intragluteal injections of quinin with defective technic Five other cases have been under observation for several months, two of them have shown no improvement under a year's treatment The men of the latest group came from the Saloniki region and the injection had been made by nurses in seven of the cases Eight of the total fifteen are improving In several of the cases the reaction of complete degeneracy was pronounced in the muscles tributary to the sciatic nerve They warn to be guided strictly by the classic directions for such injections and, in case of the slightest doubt to make the injection in the thigh For intragluteal injections the patient should be seated In the sitting position the nerve lies at a point beyond the reach of the needle They advise to insert the needle above a horizontal line crossing the extreme end of the intragluteal furrow Any point above this line is safe

45 **Suprarenal Insufficiency**—Josue emphasizes that symptoms of suprarenal insufficiency should be sought for in every infectious disease It may also form a part of the clinical picture in alimentary intoxications, chloroform and salvarsan poisoning, and in heart disease with much enlargement of the heart, the *asystolie surrenale* characterized by hypertrophy of the heart with low blood pressure, weakness, white dermographism and signs of cardiac incompetency Whatever the accompanying circumstances, suprarenal insuf-

ficiency is always serious, liable to entail even sudden death Suprarenal treatment may give unhoped-for relief in the severe and malignant forms The extract of the total gland seems preferable when toxic phenomena predominate, while epinephrin is indicated more for cardiovascular disturbance The extracts can be given by subcutaneous injection or by the mouth He advises against the intravenous route unless extra rapid and potent action is necessary

Suprarenal extracts seem to stimulate the suprarenals to regenerate Hyperplasia of the suprarenal glands has been noted in rabbits after repeated intravenous injections of epinephrin, and the suprarenals were found relatively large at necropsy of a man with suprarenal asystole and cardiac insufficiency who had long been taking occasional systematic courses of suprarenal treatment The suprarenal disturbances finally completely subsided, and at necropsy several months later, the suprarenals weighed together 16 05 gm Josue regards it as probable that the prolonged suprarenal treatment had actually induced regeneration of these glands Epinephrin given by mouth has to be in a comparatively large daily dose but fractioned into small doses throughout the day, trying to keep the patient constantly under its influence This can be long kept up without inconvenience, some of his patients have taken 3 mg of epinephrin (adrenalin) daily for a month six weeks or longer, without any disturbance therefrom In acute cases he prescribes 0 5 c c of the 1 1 000 solution in a little water, from two to ten times a day For subcutaneous injection, his dose is 0 5 c c of the 1 1,000 solution repeating often Doses of 1 mg can be kept up for a month or more These injections are generally painful Or 1 mg of the epinephrin can be added to 250 or 500 c c of physiologic salt solution Addition of 0 01 c c novocain prevents pain The slowness with which this is absorbed is an advantage

In acute infectious disease, suprarenal treatment may ward off trouble In typhoid, for instance, when the pulse grows rapid and weak, from 2 to 4 mg of epinephrin, fractioned into four or eight doses, may ward off mishaps When toxic phenomena are pronounced, as in diphtheria, he gives the total extract by the mouth and injects the epinephrin-novocain solution subcutaneously Carnot has reported good results in pernicious malaria from subcutaneous injections of the epinephrin-novocain saline, supplemented by intravenous injection of quinin This technic proved effectual without offering the dangers of intravenous epinephrin treatment

48 **Microbian Dermo-Epidermitis**—Gougerot has coined this term to denote the extensive infectious processes in the skin, especially the epidermis, which are so common among the soldiers now, and so liable to run a chronic course if eczema or trophic disturbances or other causes interfere with the early healing He says that painting the skin with a 1 50 or 1 10 solution of silver nitrate is the best antiseptic and cauterizer, promoting healing and preventing itching, and it should be applied in all cases Rest in bed the foot on a higher plane than the inguinal region, the foot and toes exercised, with light massage, are important adjuvants He gives a number of formulas for mercurial pastes, graduated for the serous, the oozing and the eczema-like cases Pastes are better than salves, and oils or creams are better than petrolatum

Presse Médicale, Paris

49 *Treatment of Tuberculous Pericarditis with Effusion by Insufflation of Air P E Weil and Loiseleur—p 601
50 Treatment of Chronic Pleural Empyema (Traitement des fistules pleurales) V Pauchet—p 604
51 Self Feeding Irrigator for Carrel Dakin Method of Treating Wounds T Tuffier—p 608

49 **Insufflation of Air in Treatment of Tuberculous Pericarditis**—Letting air into the pleura to take the place of the effusion has much simplified the treatment of pleurisy It is possible by this means to release as much as 3 or 4 liters of effusion and replace it with air at one sitting The air counteracts reproduction of the effusion and attenuates the tuberculous process, transforming a hemorrhagic or seropurulent into a merely serous effusion Weil and Loiseleur have been applying this same technic in treatment of pericarditis, and have obtained such favorable results that they commend for general adoption this method of treating tuberculous pericarditis with effusion The effect was the production of a pneumopericardium and hydropericardium, which can be watched and followed with the Roentgen rays The latter permits paracentesis with an ease and precision hitherto unknown They found it necessary to complete the withdrawal of the effusion before injecting the air They used ordinary air without special filtration and found the benefit even more striking than in pleurisy In the case of a child of 14, the procedure was repeated five times The intervals were eight, fifteen, thirty-three and forty-eight days, demonstrating the progressive improvement They compare the action of this pneumopericardium with that of induced pneumothorax, the principle and effect being practically the same The patient recovers without symphysis, preexisting adhesions being generally broken up under the pressure of the air Operative measures are superfluous, but benefit was derived from exposure of the abdomen and trunk to the direct sunlight, beginning with five-minute exposures and lengthening them to a maximum of forty minutes a day The injection of the air in an amount equal to that of the fluid tapped, caused no pain nor dyspnea nor heart symptoms in the cases described Only once was there a convulsive cough, the child had long been subject to this cough and the injection of air transiently aggravated the tendency on this occasion Several roentgenograms show the exact findings

63 Pathologic Chemistry and Metabolism in Rachitis E Schloss—p 1340

52 **Spinal Cord Tumors**—Oppenheim s first patient was a woman of 36 who recuperated practically completely after removal of a fibroma 10 5 cm long extending along the spinal cord over the entire cervical region The findings in the cerebrospinal fluid aided in the diagnosis, but in two other cases of the same kind the fluid was normal The case is the most striking one of which he knows to date demonstrating the amount of compression which the cervical spinal cord can stand without irreparable injury In the second case, a myxolipoma was removed at the upper lumbar and lower thoracic vertebrae This patient was a girl of 16 whose complaints of abdominal pain had led to a useless appendicectomy a year before The Roentgen and blood findings were normal, but the pains kept increasing and spread through the abdomem, lumbar region and left leg They were regarded as imaginary for a long time, but finally the girl was treated with extension for eight weeks It gave transient relief but then the pains grew worse, intensified by sneezing, coughing or laughing, and finally the left leg showed signs of weakness, with some paresis and atrophy of the left quadriceps, and

absent knee jerk while slight clonus of the foot could be elicited On this basis the tumor of the lumbar spinal cord was diagnosed and successfully removed Reexamination several months later showed completely normal conditions except for slight weakness in lifting the left leg, slightly interfering with climbing stairs or a hill

In conclusion he mentions some cases of chronic myelitis in which the symptoms deceptively simulated those of a tumor Laminectomy in such cases is only exploratory and may whip up the disease In another case a small tumor was correctly diagnosed and removed but the patient succumbed to weak heart action a few hours later The pulse had been somewhat accelerated but not enough to warn of imminent danger In another case an obese woman of 65 with exophthalmic goiter presented symptoms of spinal-cord tumor but the sanatorium physician mistook them for hysteria and insisted on exercise He also burnt the patient during electrotherapy as her loss of sensation in the skin was not recognized A consultant diagnosed osteomalacia Oppenheim traced the symptoms to a tumor compressing the spinal cord It was easily removed but proved to be malignant, and the patient soon succumbed to weakness of the heart Even allowing for all such mishaps, tumors compressing the spinal cord seem to be one of the most grateful fields of medical-surgical endeavor

54 **Retention of Nitrogenous Waste in the Various Body Fluids**—Rosenberg tabulates the findings in regard to urea, creatinin and indican in the blood and ascitic fluid or pleural effusion in twenty-eight cases of various morbid conditions with ascites and in twenty-two with pleural effusion When there was azotemia, the urea content of the effusion in the pleura or peritoneum was from 80 to 100 per cent that of the serum The creatinin content was up to 20 per cent higher than that of the blood, while the indican content paralleled that of the blood In a third table the findings in the blood and cerebrospinal fluid are compared The latter contained from 56 to 96 per cent as much urea as the blood, but only from 37 to 75 per cent creatinin He never found indican in the cerebrospinal fluid even with the highest indicanemia

55 **Albuminoid Bodies in Expired Air**—A man blew through a cotton-stoppered crook-shaped tube into a wash-bottle containing 3 c c distilled water The water was then rapidly evaporated and chemical tests applied to the residue From this and other tests described, the presence of albuminoid bodies in the expired air was unmistakably established The amount averaged 0 000015 mg for each inspiration during quiet breathing representing a total of 0 05 mg for the twenty-four hours The proportion during speaking averaged 0 07 mg for the twenty-four hours Analyses of the findings showed a content of 0 02 mg amino-nitrogen in the air blown into the tube during twenty-four hours Tests in telephone cabinets showed marked enrichment of the air, but they also showed that the air seems to spontaneously cleanse itself About 2,200 liters air in a telephone cabinet were aspirated through a wash-bottle twelve hours after termination of the other tests The findings then were practically nil, demonstrating a self-cleansing process

58 **War Neuroses**—Mann analyzes the various methods of treatment of war neuroses and describes some of his own successful cases The hysteric manifestations in these war neuroses are the consequence of some powerful emotion which has induced, as he says, 'a physopsychic concussion" The principle of treatment for certain cases is to induce some violent new commotion which will crowd the former one to one side A pile of iron filings can be partially separated by shaking the paper holding them and then they can be reassembled in a pile by shaking again Kaufmann has been remarkably successful with his *Ueberrumpelung* method, combining startling electric measures with suggestion and exercise, the orders all in a crisp military tone and keeping up the sitting until the man is cured even if it takes two hours or more Mann has succeeded with somewhat milder means, in some cases with several months of rest alone No one method can apply to all

59 **Laws of Growth and Nourishment**—Riebesell qualifies Wamser s laws as great progress He seems to have established that the growth—the increase in weight in a given period—is inversely proportional to the gross weight (*Rohgewicht*), and that growth occurs more rapidly the more remote the end of the period of development He expresses this by formulas and Riebesell deduces from them and the individual proportions a set of figures representing the food requirements at different ages and weights

70 **Sausage Poisoning**—Schede describes an attack of botulism (*botulus* is Latin for "sausage,") in a family of five members who ate from a raw ham The pig had been slaughtered on the farm six months before About eighteen hours afterward the symptoms of botulism became apparent in the mother and two boys of 10 and 12, and the woman and the older boy died, the other recovered The father who had eaten most freely of the ham was not affected by the poisoning The only gastro-intestinal disturbances were nausea and vomiting which the older boy suppressed Extreme prostration, dryness of the mucous membrane, difficulty in swallowing and in speaking, diplopia, ptosis, absence of the knee-jerk, paresis of the bladder sphincter and other symptoms indicating severe involvement of the motor and secretory regions in the medulla oblongata were the more striking manifestations until the respiration center began to suffer The two who died succumbed to arrest of respiration Diphtheria antitoxin was given in two of the cases but without result, an antibotulism serum has been made, but it could not be procured for these cases Pilocarpin has been recommended to combat the dryness of the mucous membranes, and Schede tried it in two cases but obtained alarming results as it induced such profuse secretion of mucus in the air passages He gave 0 01 gm subcutaneously but the boy nearly suffocated from the profuse secretion that followed in the air passages, which he was unable to cough up With oxygen, heart and vessel tonics, and lowering the head, he was tided past this mishap The tenacious constipation was combated with enemas as drug purgatives might prove dangerous if they should be long retained owing to the vagus paralysis inducing the obstipation Burger advocates lavage of the stomach, even when the intoxication has been long under way On account of the paralysis of the stomach scraps of the poisonous food may be washed out with the lavage days afterward Emetics are liable to do harm on account of the paralysis of the swallowing muscles and loss of reflexes Ample nourishment should be provided, it is best given through a stomach tube Oxygen was found a great relief by one of Schede s patients Schneidemuhl commends potassium iodid on account of its efficacy in a certain paralytic affection in cattle Schede gave it to the boy that recovered, and he says that it is certainly worth a trial in every case of sausage poisoning He mentions parenthetically that the *Bacillus botulinus* finds favorable conditions for its proliferation not only in ham and sausage but also in canned beans in herrings and the like He adds that canned goods should be cooked again before serving

73 **Syphilis and Tabes from Ophthalmologic Standpoint** —Heine reviews what has been written on this subject saying that the frequency of eye troubles in syphilis can be estimated better by the statistics from general hospitals, etc rather than from ophthalmologists records In the Kiel eye clinic the optic nerve was affected in two thirds of fifty syphilitics, and there were also pupil disturbances in two-thirds while in half the cases there were disturbances in the external ocular muscles Choked disk, optic neuritis and neuritic atrophy speak for syphilis rather than tabes Uhthoff's report on 100 cases of cerebral syphilis stated that simple atrophy of the optic nerve was found in 10 or 15 per cent of all cases of tabes, but was rare in syphilis

75 **Rectal Gonorrhea in Children** —Stumpke has had eighty-eight little girls with gonorrhea in his service at Hanover-Linden, including seven infants Since 1913 rectal gonorrhea has been found in 55 9 per cent of the fifty-nine examined The rectal involvement is extremely difficult to cure, in a number of cases the findings in the rectum were still positive months after the vagina and urethra had been restored to normal In a few cases the positive findings at first were followed by constantly negative, suggesting accidental or casual contamination The only manifestations of gonorrheal processes in the rectum are swelling of the extremely red mucosa at the point affected No tendency to ulceration was ever noted

76 **Hard Edema** —Nagy reports a case which illustrates how lymph can become extravasated and cause disturbances like those of a hematoma Also how prompt benefit follows incision into the fascia and ligaments, supplemented by elastic compression when the painful stage is past

91 **Treatment of Incontinence of Urine and Enuresis** —Fuchs and Gross comment on the remarkable frequency of incontinence of urine among the soldiers on active duty A history of trauma, getting chilled, or infectious disease was found in every case, and examination of the bladder showed that the body was in a state of maximal contracture The sphincter region seemed to be normal It was impossible to inject more than a small amount of fluid into the bladder, anything beyond this caused much pain These and other facts observed suggested that local heat might relieve the contracture and this was confirmed by experience Prompt relief followed and the incontinence was conquered by rinsing out the bladder with warmer and warmer fluids, reaching a temperature of from 45 to 48 C The idea that paralysis of the bladder is always responsible for incontinence thus has to be abandoned Under the influence of the hot irrigation the contracted musculature relaxes and the incontinence is cured The incontinence has not returned in any of the cases during the months since this simple measure proved effectual They suggest a trial of it in tabetic incontinence or with other spinal processes In the ten cases of incontinence after trauma a complete cure was realized in six and great improvement in three, two were cured and four improved in the eight cases traceable to getting chilled and four cured and two much improved in ten cases of incontinence following cholera typhoid or other infectious disease In five cases of pollakiuria with relative incontinence a complete cure was speedily realized in all They injected from fifteen to twenty syringefuls at one sitting repeating the fifteen or twenty minute sitting daily The incontinence was of less than four weeks' standing in all, and the success was more constant in the more recent cases Enuresis nocturna seems to be due to some congenital disturbance in the innervation, some insufficiency of the lower segments of the spinal cord, and the hot rinsing of the bladder has no effect on it

96 **Malaria in Austrian Army** —Zweig and Matko state that as the war has taken the troops into various malarial regions the number of cases of malaria is constantly increasing Quinin prophylaxis has not proved as effectual as had been hoped In the Italian army the drop from 50 per thousand cases of malaria in 1900 to 5 per thousand in 1910 is attributed to the systematic quinin prophylaxis In the Austrian army it was not applied early enough and the technic may have been imperfect When malaria is once installed a course of quinin treatment for at least two months is necessary Even the slightest temperature above normal is a warning that the malaria has not been conquered Measures to bring on an attack, hoping thus to disclose the latent carriers, were always unsuccessful The only safe way is to treat all for two months as if certain they are carriers In nine of their recent 100 cases, after a single severe attack there were no further symptoms, although no treatment had been applied These persons must have had natural defensive bodies which conquered the infection at the start

101 **Bile Enrichment of Urine** —Trawinski tabulates his findings showing that positive findings were obtained in 50 per cent more of the tests when bile was mixed with the

urine Of the 421 specimens of urine pathogenic germs were found in over 22 per cent but this proportion rose to over 33 when 15 c c of beef gall was added to each 3 c c of urine

106 **Antimony in Internal Leishmaniasis** —Marinucci describes two typical cases out of more extensive experience to show the effect on the fever curve of intravenous injection of antimony and potassium tartrate The children were 2 and 4 years old and had been having irregular fever for nine and four months, with pallor, loss of weight and protuberant abdomen This drug intravenously and sodium acetyl p-aminophenyl tartrate subcutaneously seem to act by their chemical action, destroying the parasites like the natural process from production of antibodies These drugs also have a hemolyzing action but this is secondary, although it can be traced in the fever curve

107 **Serum Reactions in Epidemic Meningitis** —Romano gives tabulated details of his tests The deviation of complement with serum and cerebrospinal fluid was inconstant, but occurred more frequently after the sixth day of the disease while the Vincent and Bellot test with the cerebrospinal fluid gave positive findings earlier, sometimes the first day of the disease In the six cases tabulated it was positive in four, and these were at the third to the seventh day of the disease

116 **Salicylic Medication** —Yanovsky expatiates on the importance of giving the exactly proper dose of any drug we are using Any excess is liable to have a *toxic action* and counteract the therapeutic influence, while with too small a dose we not only deprive the organism of the aid it is in our power to bestow, but the drug in small amounts may have some unanticipated action Too many administer drugs in rather haphazard fashion, not appreciating the importance of exact individual dosage Yanovsky discusses here salicylic medication, saying that the proper dose of sodium salicylate in all cases of articular rheumatism and in severe muscular and tendon rheumatism is from 2 5 to 4 or 5 gm in the twenty-four hours If this does not bring improvement in three days, he changes to pure salicylic acid treatment, giving 0 6 gm four times a day By these means he has treated not less than 200 patients with rheumatism, and they proved effectual in all but three or four, although many of the cases in soldiers were exceptionally serious He reports a few typical cases of acute rebellious and recurring articular rheumatism and of persisting endocarditis to illustrate the prompt efficacy of the salicylic acid alone or after failure of other methods of salicylic medication In the most serious cases he supplemented the four powders of 0 6 gm salicylic acid during the day with 0 4 gm acetylsalicylic acid

The fear of injurious action on the heart has no foundation in fact, it is a traditional survival of the unfortunate experiences with the salicylates when they were first introduced many years ago, and they were given in enormous doses and for all kinds of troubles In reference to any injurious action on the kidneys he cites some recent experiences with epidemics, especially one hospital epidemic of infectious sore throat in which there was a complicating hemorrhagic nephritis This occurred just as regularly in those who had not been given salicylic medication as in those who had He found that pure salicylic acid is no more liable to induce disturbances in the digestive tract than any of its preparations while it is more effectual and more reliable He begins with this and then, as the patient improves, he changes to sodium salicylate For endocarditis he gives 1 or 1 5 gm during the twenty-four hours In conclusion he commends for local application Bourget's salve as effectual and nonirritating although it contains 25 per cent salicylic acid The formula is 12 5 parts salicylic acid, 8 parts turpentine and 42 parts lard It is inexpensive and colorless, rubs in easily, and does not turn rancid

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

December 9 1916 II No 24 pp 2061 2132

120 *The Work of the Railroad Physician (De positie van den spoorwegarts) L W H T Willink —p 2064
121 *Goiter in the Netherlands (Over het voorkomen van struma) B D G Kappenburg —p 2079
122 *Local Anesthesia for Children (Plaatselijke gevoelloosmaking bij kinderen) E H La Chapelle —p 2085

120 **The Railroad Physician** —Willink's article was the opening address at the recent conference of the organized medical officials of the railroads of the Netherlands He discussed in turn the three aspects of the work of the railroad physician as clinician and surgeon, in certifying to the fitness of applicants for positions, and as the confidential adviser of the railroad company Improvement in contract conditions was one of the main objects of the conference, and Willink remarked that there was great room for improvement But he rejects the principle of free choice of a physician for railroad employees, mentioning a number of reasons why it is unwise under these circumstances Among them he notes that it would be impossible to give free passes on the railroad to all outside physicians, while ample facilities for reaching the sick employees are indispensable Another reason is that the contract physician feels his responsibility to the company and when he finds a block-signal man, for instance, suffering from overwork and nervousness, he not only orders him to take a vacation and rest, but he telephones the man higher up to ensure that his directions are enforced

121 **Goiter in the Netherlands** —Kappenburg recently reported that a goiter was manifest in 11 per cent of 493 nurses or attendants at the public hospital of Utrecht Recruiting officers have also called attention to the prevalence of goiter among recruits from Utrecht Examination of other nurses elsewhere revealed a total of 95 with goiter out of 611, that is, nearly 16 per cent A tabulation of their home towns shows anew the prevalence of goiter in those from the

[illegible]

Utrecht district, with Amsterdam a close second But in two other river districts the proportion was still higher, namely, 6 4% and 9 2% nurses with and without enlarged thyroids The figures show further a preponderance of goiter in the *nurses who have served in the care of the insane* Does this tend to induce goiter, he asks, or are nurses with a predisposition to goiter attracted more to the care of the mentally diseased?

122 **Local Anesthesia for Children**—La Chapelle reviews his experience with various operations done on children under 7 with local anesthesia alone The list includes 9 herniotomies on children under 4 There were no mishaps or drawbacks, and no *restlessness except at the first prick of the* needle and this was no more than is observed at the outset of general anesthesia On the whole, his impression is that local anesthesia is about as applicable to children as to adults Even with the latter it is advisable to divert the attention from the operation The advantages of avoiding general anesthesia are likewise the same as for adults He mentions in proof of this that one boy of 10 whose appendix was removed under local anesthesia had an infant brother apparently healthy, who died a few hours after a small nevus on the forehead had been excised under general anesthesia

123 **Suture of Bronchus and Drainage of the Pleura**—The work was done on twenty-four dogs, as is related in detail The device with which the pleura was drained is also illustrated and its advantages over other methods for the purpose are emphasized It can be applied and removed without an anesthetic while it permits the wearer to be up and about

124 **Day Urine and Night Urine**—Jespersen's study of this subject fills twenty pages and reproduces seven typical charts showing the findings over periods up to nine days They show that less urine is secreted at night than during the day, but the specific gravity is higher at night as also the percentage of nitrogen The relative and absolute proportion of sodium chlorid is less at night, as also the absolute nitrogen content of the urine, while the relative proportion is higher at night than in the daytime

Hygiea, Stockholm

126 *Tubercle Bacilli in the Feces of Children with Tuberculosis of the Air Passages (Bidrag till frågan om det diagnostiska vardet av pavisandet av tuberkelbaciller i fæces hos barn med tuberkulos i respirationstractus) J Leffler —p 1809

127 Complications with Incarcerated Hernia Three Cases (Tre sallsynta fall av Hernia incarcerata) G Gussander —p 1831

126 **Tubercle Bacilli in Children's Stools**—Leffler analyzes the scanty literature on the finding of tubercle bacilli in the stools of children with a tuberculous process in the air passages He examined 110 children at the municipal tuberculosis sanatorium and found tubercle bacilli in the stools in 16 4 per cent The feces were examined with the Reh ether technic and also with the Engleson method, the former proving most reliable The cases are tabulated for comparison of the clinical data, and a brief summary of each of the positive cases is given including four infants and five children over 12 and three *respectively* 6 8 and 9 all with advanced physical changes and bad general condition Others with positive findings were three older children with similar advanced lesions but the general condition still good, and four with minor lesions and good general condition Five of the older children *with advanced lesions* had tubercle bacilli in the sputum, and one had considerable expectoration but no tubercle bacilli None of the other children expectorated The tables show thus that the conditions in older children are much the same as in adults Only six infants were examined, tubercle bacilli were found in the stools of all but one, con*firming the diagnosis of progressive pulmonary tuberculosis* These experiences confirm the rarity of "open" tuberculosis in children and testify against the assumption that the tubercle bacilli get into the stools by way of the blood If this were the case, the *positive findings* would probably have been more numerous

December 29 No 52 pp 2337 2350

130 *Influence of Thyroid Treatment on Standard Metabolism (Thyreoidinets Indflydelse paa Standardstofskiftet) M Krogh —p 2337

128 **Chronic Constipation**—Thaysen devotes his third article on this subject to what he calls *Ascendensobstipation*, the feces sojourning abnormally long in the ascending colon and *first part of the transverse colon* There may be excessive or deficient contractions of this part of the bowel In thirteen of Thaysen's twenty-two cases of this ascending type of chronic constipation the stasis was restricted to the ascending colon, and the Roentgen findings showed the atonic or spastic conditions responsible for the constipation He reproduces some of the roentgenograms In the other cases the roentgenograms showed stasis of feces along the ascending colon and beyond Adhesions may be responsible for stasis in the descending colon but this seems to occur but rarely, the trouble here being of functional nature in the majority of cases, either spasmodic contraction or atony or a combination of both Nine of his twenty-three cases were of the spastic type and even in the others there were occasionally symptoms suggesting spasmodic contraction He calls attention to the fact that in six of the nine spastic cases the pains were either exclusively or much stronger in the left than the right side In only two were they restricted to the right side, in one case to the epigastrium The tenderness likewise was most pronounced over the regions where the pains were felt most This suggests that when there is spastic contraction in the ascending or transverse colon, there must be an accompanying spasm in the descending colon Among the fourteen patients with constipation from atony four had no pains in the colon region, six had pains in the right iliac fossa, two in the left and two on both sides The roentgenograms show that the ascending colon is not dilated with this "ascending constipation It is liable to lead to the erroneous diagnosis of appendicitis, especially of "recurrent" appendicitis, while mucous colitis rarely entails appendicitis Four of Thaysen s patients had a temperature somewhat above normal along *with pains in the right iliac fossa confirming the assumption* of appendicitis Of Stierlin's eight patients of this type four had had appendicectomy done The disturbances in such cases persist after removal of the appendix as this does not get rid of the cause In short he concludes, the discovery of *Ascendensobstipation* should contraindicate appendicectomy even when everything seems to indicate chronic appendicitis

130 **Influence of Thyroid Secretion on the Standard Metabolism**—Krogh has had occasion to record the metabolic findings in numbers of persons with exophthalmic goiter and myxedema and has been amazed at the remarkable deviations from normal in certain respects In one case of exophthalmic goiter the standard metabolism was found 80 per cent above normal, and in a myxedema patient 40 per cent below normal It is thus rendered evident that the secretion of the thyroid promotes the metabolic changes This assumption was confirmed by experiments on five frogs, described in detail The metabolic findings showed a pronounced increase under the action of thyroidin, although the animals were entirely under the influence of an anesthetic
